Abstract

Measurements of spin observables in $pp \rightarrow \vec{p}\vec{p}\pi^0$ are suggested to remove the phase ambiguity of the threshold amplitude. The suggested measurements complement the IUCF data on $\vec{p}\vec{p} \rightarrow pp\pi^0$ to completely determine all the twelve partial wave amplitudes, taken into consideration by Mayer et. al. [12] and Deepak, Haidenbauer and Hanhart [20].

I. INTRODUCTION

Meson production in $NN$ collisions has continued to excite considerable interest [1–4], since total cross-section measurements [5] for $pp \rightarrow pp\pi^0$ in the early 1990’s were found to be more than a factor of five larger than the then available theoretical predictions [6]. To bridge the gap between experiment and theory, several mechanisms like, exchange of heavy mesons, two pion exchange, off shell extrapolation of the vertex form factor, final state interactions, contributions due to Δ resonance and of low lying nucleon resonances, were proposed. Hanhart et al. [7] in 2000 have observed: “As far as mixing in any of the spin observables measured in [15], the triplet to triplet. Pionic dπ to pπ are also expected to contribute, which are, however, triplet to triplet. Picionic d-wave effects were reported [8] even at a beam energy of 310 MeV. Measurements up to 425 MeV have also been reported [9], where evidence for $Ds$ state was seen even at 310 MeV. Advances in storage ring technology [10] led to detailed experimental studies, including measurements of spin observables employing polarized beams of protons on polarized proton targets. Of the two existing models [11, 12] which include higher partial waves, the Julich meson exchange model [11] was thoroughly confronted with these data. The model was comparatively more successful with the less complete data on $\vec{p}\vec{p} \rightarrow d\pi^+$ [13] and $\vec{p}\vec{p} \rightarrow p\pi^+$ [13], but failed to provide an overall satisfactory reproduction of the complete set of polarization observables in the case of $\vec{p}\vec{p} \rightarrow pp\pi^0$. In this context, a model independent approach [16, 17], was developed, using irreducible tensor techniques [18]. The reaction is characterized, in this formalism, by irreducible tensor amplitudes $M_\lambda^i(s_f, s_i)$ of rank $\lambda = \{s_f - s_i|, ... (s_f + s_i)$, where $s_i, s_f$ denote the initial and final spin states of the two protons. Each of these amplitudes is expressible in terms of partial wave amplitudes $M_\lambda^l(\lambda s_f, \lambda s_i)$, which are functions of the c.m. energy $E$ and invariant mass $W$ of the two proton system in the final state. The relative orbital angular momentum between the two protons in the initial and final states are denoted by $l_i$ and $l_f$ respectively and $l$ denotes the pion orbital angular momentum in the c.m frame. The threshold amplitude $M_{00;0,1}$ contributes to $M_1^0(0, 1)$, and an empirical estimate of the integrated $|M_1^0(0, 1)|^2$ was presented in [16], based on the then existing data [3]. The same approach was employed subsequently to analyze [19] the IUCF data on $\vec{p}\vec{p} \rightarrow pp\pi^0$ immediately after its publication. The sixteen partial waves listed by Mayer et al. [15], covered the $Ss, Ps, Pp, Sd$ and $Ds$ channels. Here, the capital letters denote $l_f$ while the lower case indicate $l$. In [20], the same set of partial waves were listed, of which, the last four, covering $Sd$ and $Ds$ were ignored following [15]. Since, the final spin-singlet and spin-triplet states do not mix in any of the spin observables measured in [15], the $Ss$ amplitude and the larger of the $Ps$ amplitude were both chosen to be real in [20]. This implies that the phase of the $Ss$ amplitude remained ambiguous but chosen to be zero with respect to the larger $Ps$ amplitude. The comparison of the empirically extracted amplitudes with the Julich model predictions revealed that $i)$ the $\Delta$ contributions are important, $ii)$ the model deviated very strongly in the case of $^3P_1 \rightarrow ^3P_0p$ and to a lesser extent in $^3F_1 \rightarrow ^3P_0p$ which will guide the search for the possible shortcomings.” [20]

The purpose of the present paper is to extend the model independent theoretical discussion to the spin polarization of the protons in the final state and to examine how the additional experimental measurements regarding the final spin state can be used to determine empirically, the strengths of all these amplitudes and the ambiguous
II. THEORETICAL FORMALISM

We consider the reaction $pp \rightarrow pp\pi^0$ at c.m. energy $E$ and initial c.m. momentum $\mathbf{p}_i = p\hat{\mathbf{p}}_i$ which may be chosen to be along the $z$-axis. Let $q = q\hat{q} = -(\mathbf{p}_1 + \mathbf{p}_2)$ denote the pion momentum in c.m. frame and let $\mathbf{p}_f = p\hat{\mathbf{p}}_f = p_0(\mathbf{p}_1 - \mathbf{p}_2)$ in terms of the c.m. momenta $\mathbf{p}_1$ and $\mathbf{p}_2$ of the two protons in the final state.

Following [16], we write the matrix $M$ in spin space for the reaction $pp \rightarrow pp\pi^0$ in the form

$$M = \sum_{\mathcal{L}, j} W(\nu_1 \nu_2 \nu_3 \nu_4; j \lambda) Z(s_f, s_i, \mathcal{L}, j) \times A^\lambda(\mathcal{L}),$$

(1)

where $s_i$ and $s_f$ denote the initial and final channel spins respectively. The irreducible tensor operators $S^\lambda(\nu_1 \nu_2; s_i)$ of rank $\lambda$ with taking values $\mu$ taking values $\mu = \lambda, \lambda - 1, \ldots, -\lambda$ are defined in [13]. The irreducible tensor amplitudes $M(\nu_1 \nu_2; s_i)$ in (1) are expressible as

$$M^\lambda(\nu_1 \nu_2; s_i) = \sum_{\mathcal{L}, j} W(\nu_1 \nu_2 \nu_3 \nu_4; j \lambda) Z(s_f, s_i, \mathcal{L}, j) \times A^\lambda(\mathcal{L}),$$

(2)

and the symbol $\mathcal{L}$ is used to collectively denote $\mathcal{L} = \{ l_1, l, L_f, l_1 \}$. It may be noted that $(-1)^{l_f + i_l + i_i} = -1$ due to parity conservation. The complex numbers $Z(s_f, s_i, \mathcal{L}, j)$ are given by

$$Z(s_f, s_i, \mathcal{L}, j) = \frac{[l_1][j][j_l]}{[s_f]} (-1)^{j_s + 1} \sum_{j_f} W(s_f l_2 j f [j_f] M^j(l_f s_f) j_f; j s_i)$$

(4)

in terms of the sixteen partial wave reaction amplitudes $M^j(l_f s_f) j_f; j s_i$ proportional to the reduced on-energy-shell $T$ matrix elements $(l_f s_f) j_f j |T||l_s j)$ for the reaction. The purely kinematical factor

$$F = (-1)^{l_1 + l_f} 4(2\pi)^{1/2} \sqrt{W \omega(E - \omega) q p f / p i},$$

(6)

is introduced explicitly in [13], so that the dependence on $E$ and $W$ is seen to be completely taken care of by the $M^j(l_f s_f) j_f; j s_i$. They are identical to the amplitudes denoted as $T$ in [20]. We may, following [13, 20], neglect the last four amplitudes which are $Sd$ and $Ds$ and consider the first twelve amplitudes, which are, for simplicity, enumerated as $f_1, \ldots, f_{12}$ in Table 1.

The unpolarized double differential cross section may now be written as

$$\frac{d^2 \sigma_0}{dW d\Omega_f d\Omega} = \frac{1}{4} T^\dagger[M M^\dagger],$$

(7)

where $M^\dagger$ denotes the hermitian conjugate of $M$ given by $\Omega$. The invariant mass $W$ of the two protons in the final state is given by

$$W = (E^2 + m^2 - 2E\omega),$$

(8)

where $m$ denotes the pion mass and $\omega$ denotes the c.m. energy of pion. It may be noted that

$$\frac{d^2 \sigma_0}{d^2 p_f d\Omega} = \frac{W}{p_f} \frac{d^2 \sigma_0}{d^3 p_f d\Omega d\Omega},$$

(9)

It is worth noting that the threshold $Ss$ amplitude $f_1$ alone contributes to

$$M^l(0, 1) = \frac{1}{4 \sqrt{3\pi}} f_1 Y_{l \mu}(\hat{p}_i),$$

(10)

which is spherically symmetric both w.r.t $\hat{p}_f$ as well as $\hat{q}$ in the final state, while all the other irreducible tensor amplitudes are independent of $f_1$.

III. FINAL STATE POLARIZATION WITH INITIALLY UNPOLARIZED PROTONS.

If the colliding protons are unpolarized, the spin density matrix $\rho^f$ characterizing the two protons in the final state is given by

$$\rho^f = \frac{1}{4} M M^\dagger,$$

(11)
so that (7) is identical with $Tr[\rho^f]$. The final spin state is completely determined through measurements of the polarizations

$$P_i = \frac{Tr[\sigma_i \rho^f]}{Tr[\rho^f]}, \quad i = 1, 2 \quad (12)$$

of the two protons and their spin-correlations

$$C_{\alpha\beta} = \frac{Tr[\sigma_{1\alpha} \sigma_{2\beta} \rho^f]}{Tr[\rho^f]}, \quad \alpha, \beta = x, y, z. \quad (13)$$

All these spin observables may elegantly be calculated by considering

$$P^k_\mu(s', s_f) = Tr[S^k_\mu(s', s_f) \rho^f], \quad (14)$$

where $S^k_\mu(s', s_f)$ are given in terms of the Pauli spin matrices $\sigma_1$ and $\sigma_2$ of the two protons in the final state through

$$S^0_\mu(0, 0) = \frac{1}{2}(1 - \sigma_1 \cdot \sigma_2) \quad (15)$$

$$S^0_\mu(1, 1) = \frac{1}{2}(3 + \sigma_1 \cdot \sigma_2) \quad (16)$$

$$S^1_\mu(1, 1) = \frac{\sqrt{3}}{2\sqrt{2}}(\sigma_1 + \sigma_2)_\mu \quad (17)$$

$$S^2_\mu(1, 1) = \frac{\sqrt{3}}{2\sqrt{2}}(\sigma_1 \otimes \sigma_2)_\mu^2 \quad (18)$$

$$S^3_\mu(0, 1) = \frac{1}{2\sqrt{2}}(\sigma_1 \otimes \sigma_2)_\mu - \frac{1}{4}(\sigma_1 - \sigma_2)_\mu^2 \quad (19)$$

$$S^3_\mu(1, 0) = \frac{\sqrt{3}}{2\sqrt{2}}(\sigma_1 \otimes \sigma_2)_\mu^1 + \frac{\sqrt{3}}{4}(\sigma_1 - \sigma_2)_\mu^1. \quad (20)$$

Thus, the double differential cross section is given by

$$\frac{d^2\sigma_0}{dW \, d\Omega_f \, d\Omega_l} = Tr[\rho^f] = P^0_0(0, 0) + P^0_0(1, 1), \quad (21)$$

in terms of the double differential cross sections $P^0_0(0, 0)$ leading to the final singlet state and $P^0_0(1, 1)$ leading to the final triplet state of the two protons. If we use the notations $(P_1)_\mu$ to denote the spherical components, i.e.,

$$(P_1)_0 = P_{z1}; (P_1)_{\pm 1} = \mp \frac{1}{\sqrt{2}}(P_{x1} \pm P_{y1}), \quad (22)$$

it follows from (19) and (20) that

$$P^1_\mu(1, 0) - \sqrt{3}P^1_\mu(0, 0) = \frac{\sqrt{3}}{2} Tr[\rho^f] (P_1 - P_2)_\mu, \quad (23)$$

where as it follows from (17) that

$$P^1_\mu(1, 1) = \frac{\sqrt{3}}{2\sqrt{2}} Tr[\rho^f] (P_1 + P_2)_\mu, \quad (24)$$

which together determine $P_1$ and $P_2$ individually. Finally, the spin correlations $C_{\alpha\beta}$ defined in (13) may like wise be related to (14) using

$$P^0_0(1, 1) - 3P^0_0(0, 0) = Tr[(\sigma_1 \cdot \sigma_2) \rho^f], \quad (25)$$

$$P^1_\mu(1, 0) + \sqrt{3}P^1_\mu(0, 1) = \frac{\sqrt{3}i}{2} Tr[\rho^f (\sigma_1 \times \sigma_2)]_\mu. \quad (26)$$

Using the known properties of the spin operators $S^k_\mu$ and standard Racah techniques, we may obtain a master formula for all the final state spin observables, which is given by

$$P^k_\mu(s', s_f) = \frac{1}{4} \sum_{s_i, \lambda, \lambda'} (-1)^{s_f - s_i}[s_f][s'_f]^{2}[[\lambda][\lambda']} \times W(s'_f, s_f; s_i k) \times (M^{\lambda}(s_f, s_i) \otimes M^{\lambda}(s'_f, s_i))_\mu^k, \quad (28)$$

where $M^{\lambda}(s_f, s_i)$ are defined in terms of the complex conjugates $M^{\lambda}(s_f, s_i)^*$ of $M^{\lambda}(s_f, s_i)$ given by (2) through

$$M^{\lambda}(s_f, s_i) = (-1)^{1-\lambda} \sum_{\lambda'} W(l, s_i L_f s_f; j \lambda) \times Z^{*}(s_f, s_i, j, \lambda) A^{\lambda}_{\lambda'}(\lambda), \quad (30)$$

where $Z^{*}(s_f, s_i, j, \lambda)$ denote the complex conjugates of $Z(s_f, s_i, j, \lambda)$ given by (3).

IV. RELATIVE PHASE OF THE THRESHOLD AMPLITUDE

We may now take advantage of the fact that $M^0_0(0, 1)$ given by (10) is spherically symmetric with respect to $P_f$ and $\bar{q}$ and involves only the threshold amplitude $f_1$. Moreover, $M^0_0(1, 1)$ are independent of $f_1$ and depend only on the $\bar{q}p$ amplitudes $A_{f_1}, \ldots, A_{f_{12}}$. Therefore, we focus attention on (2) and (3) which involve

$$(M^{\lambda}(1, 1) \otimes M^{\lambda}(0, 1))_\mu = \frac{1}{4\sqrt{3}i} \sum_{\lambda, \mu} W(l_1 L_f 1; j \lambda) \times Z^{*}(1, 1, j, \lambda) f^0_1 \times (A^{\lambda}(\lambda) \otimes Y_1(\hat{p}_1))_\mu^1, \quad (31)$$

$$(M^1(0, 1) \otimes M^{\lambda}_{11}(1, 1))_\mu = \frac{-1}{4 \sqrt{3}i} \sum_{\lambda, \mu} W(l_1 L_f 1; j \lambda) \times Z^{*}(1, 1, j, \lambda) f_1 \times (A^{\lambda}(\lambda) \otimes Y_1(\hat{p}_1))_\mu^1, \quad (32)$$

Expressing

$$(A^{\lambda}(\lambda) \otimes Y_1(\hat{p}_1))_\mu = \frac{\sqrt{3}}{4\pi} \sum L_i W(L_f l_1 11; \lambda L_i) \times \lambda[L][L_i] C(l_1 L_i, 000) \times A^{\lambda}(l_1 L_f L_i), \quad (33)$$
and carrying out the summation over \( \mathcal{L} \) and \( j \), we obtain

\[
P^1_\mu(1,0) = f_1^* [F_1^* A^1_\mu(1110) + F_2^* A^1_\mu(1112) + F_3^* A^1_\mu(1122)], \quad (34)
\]

\[
P^1_\mu(0,1) = -\frac{1}{\sqrt{3}} f_1 [F_1^* A^1_\mu(1110) + F_2^* A^1_\mu(1112) + F_3^* A^1_\mu(1122)], \quad (35)
\]

where \( F_i, i=1,2,3 \) are well-defined linear combinations of the \( pp \) amplitudes given by

\[
F_1 = \frac{1}{32\pi^{3/2}} \left[ f_4 - \frac{5}{6} f_5 + \frac{5}{2\sqrt{3}} f_6 + \frac{1}{3\sqrt{3}} f_7 - \frac{1}{6} f_9 - \frac{\sqrt{5}}{6\sqrt{3}} f_{11} \right],
\]

\[
F_2 = \frac{1}{32\sqrt{2}\pi^{3/2}} \left[ f_5 - \sqrt{3} f_6 + \sqrt{\frac{3}{2}} f_7 + \frac{3}{\sqrt{2}} f_8 \right],
\]

\[
F_3 = -\frac{1}{32\sqrt{2}\pi^{3/2}} \left[ \sqrt{3} f_5 + f_6 + \sqrt{7} f_7 + \sqrt{\frac{7}{3}} f_8 \right].
\]

Since the \( pp \) amplitudes have been determined both in magnitude and relative phase w.r.t \( f_2 \) in [20], we may express

\[
F_\alpha = |F_\alpha| e^{i\Delta_\alpha}, \alpha = 1,2,3
\]

and treat \( |F_\alpha| \) and \( \Delta_\alpha \) as known. In [20], \( f_2 \) was assumed to be real. Since the relative phase between \( f_1 \) and \( f_2 \)
could not be ascertained from the measurements of Meyer et al. [15], \( f_1 \) was also assumed to be real, although only one of the amplitudes can be taken as real. Therefore, we choose \( f_2 \) to be real and express \( f_1 \) as

\[
f_1 = |f_1| e^{i\delta_1}, \quad (40)
\]

This leads to

\[
P^1_\mu(1,0) - \sqrt{3} P^1_\mu(0,1) = 2 \sum_{\alpha=1}^3 R_\alpha \text{cos}(\Delta_\alpha - \delta_1) A^1_\mu(\alpha), \quad (41)
\]

\[
P^1_\mu(1,0) + \sqrt{3} P^1_\mu(0,1) = 2i \sum_{\alpha=1}^3 R_\alpha \text{sin}(\Delta_\alpha - \delta_1) A^1_\mu(\alpha), \quad (42)
\]

where \( R_\alpha = |F_\alpha|/|f_1| \) and \( A^1_\mu(\alpha) \) for \( \alpha = 1,2,3 \) denote \( A^1_\mu(1110), A^1_\mu(1112), A^1_\mu(1122) \) respectively.

It is seen from (11) that measuring the double differential crosssection (7) yields \( T_r[\rho^\mu] \). Measurements of \( (P_1 - P_2)_\mu \) given by (23) then leads to empirical determination of (11), while measurements of spin correlations \( C_{xy} - C_{yx}, C_{yz} - C_{zy}, C_{zx} - C_{xz} \) where \( C_{\alpha\beta} \) are given by [13] lead to empirical determination of (12) using (26).

Thus, we find that it is possible to determine empirically the relative phase \( \delta_1 \) of \( f_1 \), without any trigonometric ambiguities, since \( R_\alpha \) and \( \Delta_\alpha \) are known from [20]. We therefore advocate measurement of these \( pp \) spin observables in the final state, employing simply an unpolarized beam and unpolarized target initially, to complement the spin observables measured by Meyer et al. [15], so that the amplitudes \( f_1, f_2, \ldots, f_{12} \) may be determined empirically without any phase ambiguity.
