A strong “abc-conjecture” for certain partitions a+b of c

Constantin M. Petridi
cpetridi@hotmail.com

Abstract We prove that for any positive integer $c$ and any $\varepsilon > 0$ there are representations of $c$ as a sum $a + b$ of two co-prime positive integers $a$, $b$, such that the respective radicals $R(abc)$ satisfy

$$k\varepsilon \, R(c)^{1-\varepsilon} \, c^2 < R(abc),$$

where $k\varepsilon$ is an absolute constant depending only on $\varepsilon$. For the representations in question this is a stronger result than the abc-conjecture

$$k\varepsilon \, c^{1+\varepsilon} < R(abc).$$

An upper bound, depending on the number of prime factors of $c$, is also established.

Preliminaries. Let $c = q_1^{\alpha_1}q_2^{\alpha_2}\cdots q_\omega^{\alpha_\omega}$, $q_i$ different primes, $\alpha_i \geq 1$, be a positive integer. Denote its radical $q_1q_2\cdots q_\omega$, by $R(c)$, and similarly $R(n)$ for any integer $n$. Consider the positive solutions of the Diophantine equation $x + y = c$, $(x, y) = 1$, $x < y$. Their number is $\varphi(c)/2$. Denoting them in some order by $a_i$, $b_i$, $1 \leq i \leq \varphi(c)/2$, and listing them with their respective radicals, one has

\begin{align*}
a_1 + b_1 &= c & R(a_1b_1c) \\
a_2 + b_2 &= c & R(a_2b_2c) \\
\cdots & & \cdots \\
a_{\varphi(c)/2} + b_{\varphi(c)/2} &= c & R(a_{\varphi(c)/2}b_{\varphi(c)/2}c).
\end{align*}

Form the product of above radicals

$$G_c = \prod_{1 \leq i \leq \varphi(c)/2} R(a_ib_ic).$$

$G_c^{\varphi(c)/2}$ is the geometric mean of the radicals.

The function $E_c(x)$ defined for any real $x \neq 0$ by

$$E_c(x) = \left[\frac{1}{x}c\right] - \sum_{1 \leq i \leq \omega} \left[\frac{1}{x}c\right]_{q_i} + \sum_{1 \leq i,j \leq \omega} \left[\frac{1}{x}c\right]_{q_iq_j} - \cdots + (-1)^\omega \left[\frac{1}{x}c\right]_{q_1\cdots q_\omega},$$
plays a key role in our investigations. If the numbers in the integral part
brackets are integers the function reduces to
\[
\frac{1}{x} - \sum_{1 \leq i \leq \omega} \frac{1}{x q_i} + \sum_{1 \leq i, j \leq \omega} \frac{1}{x q_i q_j} - \cdots + (-1)^\omega \frac{1}{x} \frac{c}{q_1 \cdots q_\omega} = \frac{1}{x} \varphi(c).
\]
Throughout the paper, \(p\) designates prime numbers.

**Theorem 1.**

\[ G_c = R(c)^{\frac{\varphi(c)}{x}} \prod_{2 \leq p < c, (p, c) = 1} p^{E_p(c)}. \]

**Proof.** Consider all positive solutions of the Diophantine equation \(x + y = c, \ x \leq y\), and their corresponding radicals \(R(xyc)\)

\[
\begin{align*}
1 + (c - 1) &= c & R(1(c - 1)c) \\
2 + (c - 2) &= c & R(2(c - 2)c) \\
& \cdots & \cdots \\
\left[\frac{c}{2}\right] + (c - \left[\frac{c}{2}\right]) &= c & R \left( \left[\frac{c}{2}\right] c \right)
\end{align*}
\]

Above equalities comprise (1), but include also those for which \((x, y) > 1\).
That all \(q_i\) appear \(\frac{\varphi(c)}{2}\) times in \(G_c\) is obvious. Consequently, so does their product \(R(c)\). For primes \(p \neq q_i\), we apply the inclusion-exclusion principle.
As all numbers \(< c\) do occur in the equalities (2), the number of times \(p\) appears in the radicals (2) is \(\left[\frac{c}{p}\right]\). The number of times \(pq_i\) appears in the radicals (2) is \(\sum_{i, j} \left[\frac{c}{pq_i q_j}\right]\), e.t.c. Inserting these values in the inclusion-exclusion formula we get for the total number of times \(p\) appears in the radicals (1)

\[
\left[\frac{1}{p} \frac{c}{1}\right] - \sum_{1 \leq i \leq \omega} \left[\frac{1}{p q_i}\right] + \sum_{1 \leq i, j \leq \omega} \left[\frac{1}{p q_i q_j}\right] - \cdots + (-1)^\omega \left[\frac{1}{p} \frac{c}{q_1 \cdots q_\omega}\right] = E_p(c),
\]

as stated in the theorem.

**Corollary.** If \(d\) denotes the divisors of \(c\), then

\[
\prod_{d|c} G_d = \prod_{2 \leq p < c, (p, c) = 1} p^{E_p(c)}.
\]
where
\[ \Theta(q_i) = \sum_{d=0(q_i)}^{\varphi(d) \over 2} + \sum_{d \neq 0(q_i)}^{E_d(q_i)}. \]

**Proof.** Applying Theorem 1 to the divisors \( d \) of \( c \) one has
\[ G_d = R(d) {\varphi(d) \over 2} \prod_{p \leq d \atop (p, d) = 1} p^{E_d(p)}. \]

Multiplying over all \( \tau(c) \) divisors and using the, easily established, fact that
\[ \prod_{x+y=c \atop x \leq y} R(xyc) = R(c)^{\omega_x} \prod_{2 \leq p < c \atop (p, c) = 1} p^{\varphi(c)}, \]
gives for \( \prod_{d \mid c} G_d \) the result.

The corollary will not be used in the sequel.

We shall now prove certain Lemmas regarding the function \( E_c(x) \), and state, without proof, some well known facts from the elementary theory of primes, so as not to interrupt the main body of the proof. Absolute constants will be denoted by \( k_i \), indexed in the order they first appear.

**Lemma 1.** For \( x > 0 \) (actually for any \( x \neq 0) \)
\[ Max \left( 0, \frac{\varphi(c)}{x} - 2^{\omega - 1} \right) < E_c(x) < \frac{\varphi(c)}{x} + 2^{\omega - 1}. \]

**Proof.** By definition one has
\[ \frac{1}{x} < \frac{\varphi(c)}{x} < \frac{1}{x} \]
\[ - \sum_{1 \leq i \leq \omega} \frac{1}{x \ q_i} \leq - \sum_{1 \leq i \leq \omega} \left[ \frac{1}{x \ q_i} \right] < \left( \frac{\omega}{1} \right) - \sum_{1 \leq i \leq \omega} \frac{1}{x \ q_i} \]
\[ \sum_{1 \leq i \leq \omega} \frac{1}{x \ q_i q_j} - \left( \frac{\omega}{2} \right) < \sum_{1 \leq i, j \leq \omega} \left[ \frac{1}{x \ q_i q_j} \right] \leq \sum_{1 \leq i, j \leq \omega} \frac{1}{x \ q_i q_j} \]
\[
\frac{1}{x q_1 \cdots q_\omega} - \left( \frac{\omega}{c} \right) < (-1)^\omega \left[ \frac{1}{x q_1 \cdots q_\omega} \right] \leq \frac{1}{x q_1 \cdots q_\omega}, \quad \omega \equiv 0(2)
\]

\[
-\frac{1}{x q_1 \cdots q_\omega} \leq -1)^\omega \left[ \frac{1}{x q_1 \cdots q_\omega} \right] < \left( \frac{\omega}{c} \right) - \frac{1}{x q_1 \cdots q_\omega}, \quad \omega \equiv 1(2).
\]

Adding term-wise above inequalities, we have

\[
\frac{1}{x} \left\{ c - \sum_{1 \leq i \leq \omega} \frac{c}{q_i} + \sum_{1 \leq i,j \leq \omega} \frac{c}{q_i q_j} - \cdots \right\} - \sum_{\nu \equiv 0(2)} \left( \frac{\omega}{\nu} \right) < E_c(x) < \frac{1}{x} \left\{ c - \sum_{1 \leq i \leq \omega} \frac{c}{q_i} + \sum_{1 \leq i,j \leq \omega} \frac{c}{q_i q_j} - \cdots \right\} + \sum_{\nu \equiv 1(2)} \left( \frac{\omega}{\nu} \right).
\]

Considering that

\[
\sum_{\nu \equiv 0(2)} \left( \frac{\omega}{\nu} \right) = \sum_{\nu \equiv 1(2)} \left( \frac{\omega}{\nu} \right) = 2^{\omega-1},
\]

and since \( E_c(x) \) is the \# of numbers \( n \leq \frac{c}{x}, (n,c) = 1 \), i.e. always \( \geq 0 \), we have, as required,

\[
Max \left( 0, \frac{\varphi(c)}{x} - 2^{\omega-1} \right) < E_c(x) < \frac{\varphi(c)}{x} + 2^{\omega-1}.
\]

**Lemma 2.**

\[
E_c(x) > \begin{cases} 
\frac{\varphi(c)}{x} - 2^{\omega-1} & \text{for } 0 < x < \frac{\varphi(c)}{2^{\omega-1}} \\
1 & \text{for } \frac{\varphi(c)}{2^{\omega-1}} \leq x < c.
\end{cases}
\]

**Proof.** The expression \( \frac{\varphi(c)}{x} - 2^{\omega-1} \) is positive for all \( 0 < x < \frac{\varphi(c)}{2^{\omega-1}} \). For \( x \geq \frac{\varphi(c)}{2^{\omega-1}} \) the lowest limit of \( E_c(x) \) is 1, since \( x < c \).
Lemma 3. If one of the prime factors $q_i$, has exponent $\alpha_i \geq 2$ then

$$E_c(q_i) = \frac{\varphi(c)}{q_i}.$$ 

Proof. Writing $q_i$ instead of $x$ in $E_c(x)$, and renaming the running indexes, one has

$$E_c(q_i) = \left[\frac{1}{q_i} c \right] - \sum_{1 \leq j \leq \omega} \left[\frac{1}{q_i} c \frac{1}{q_i q_j} \right] + \sum_{1 \leq j, k \leq \omega} \left[\frac{1}{q_i} c \frac{1}{q_i q_j q_k} \right] - \cdots + (-1)^\omega \left[\frac{1}{q_i} c \frac{1}{q_i q_1 \cdots q_\omega} \right].$$

Since by supposition the exponent of $q_i$ is $\geq 2$, the numbers within the integral part brackets are integers so that we can skip the brackets. This gives

$$\frac{1}{q_i} c - \sum_{1 \leq j \leq \omega} \frac{1}{q_i} c \frac{1}{q_i q_j} + \sum_{1 \leq j, k \leq \omega} \frac{1}{q_i} c \frac{1}{q_i q_j q_k} - \cdots + (-1)^\omega \frac{1}{q_i} c \frac{1}{q_i q_1 \cdots q_\omega} = \frac{\varphi(c)}{q_i},$$

as stated.

Lemma 4. If one of the prime factors $q_i$ has exponent $\alpha_i = 1$, then

$$E_c(q_i) = \frac{\varphi(c)}{q_i - 1} - \frac{E_{c/q_i}(q_i)}{q_i}.$$ 

Proof. For convenience, putting $\overline{c} = c/q_i$, renaming indexes as above, and writing on the left hand side the terms of the $E_c(q_i)$ function vertically, we have following equalities

$$\left[\frac{1}{q_i} c \right] = \left[\frac{1}{q_i} \overline{c}\right]$$

$$- \sum_{1 \leq j \leq \omega} \left[\frac{1}{q_i} c \frac{1}{q_i q_j} \right] = - \left[\frac{1}{q_i} c \frac{1}{q_i} \overline{c}\right] - \sum_{2 \leq j \leq \omega} \left[\frac{1}{q_i} \frac{1}{q_i q_j} \overline{c}\right]$$

$$+ \sum_{1 \leq j, k \leq \omega} \left[\frac{1}{q_i} c \frac{1}{q_i q_j q_k} \right] = + \sum_{2 \leq j \leq \omega} \left[\frac{1}{q_i} q_i q_j \overline{c}\right] + \sum_{2 \leq j, k \leq \omega} \left[\frac{1}{q_i} q_i q_j q_k \overline{c}\right]$$

$$\cdots \cdots \cdots \cdots$$
\[
(-1)^{\omega-1} \sum_{1 \leq j, \nu \leq \omega} \left[ \frac{1}{q_i q_i q_j \cdots q_{j_{\omega-1}}} \right] c = (-1)^{\omega-1} \sum_{1 \leq j, \nu \leq \omega} \left[ \frac{q_j \bar{\nu}}{q_i q_i q_j q_j \cdots q_{j_{\omega-1}}} \right] + \]
\[
(-1)^{\omega-1} \left[ \frac{1}{q_i q_i q_2 \cdots q_\omega} \right]
\]
\[
(-1)^{\omega} \left[ \frac{1}{q_i q_1 q_2 \cdots q_\omega} \right] c = (-1)^{\omega} \left[ \frac{q_j \bar{\nu}}{q_i q_i q_j q_2 \cdots q_\omega} \right].
\]

Adding above equalities, the sum of the left hand side terms is, as stated, \( E_c(q_i) \). The right hand side is equal to
\[
\left\{ - \left[ \frac{1}{q_i q_i} \right] + \sum_{2 \leq j \leq \omega} \left[ \frac{1}{q_i q_i q_j} \right] + \cdots \right\} + (-1)^{\omega-1} \sum_{1 \leq j, \nu \leq \omega} \left[ \frac{1}{q_i q_i q_j q_j \cdots q_{j_{\omega-2}}} q_j \bar{\nu} \right] + (-1)^{\omega} \left[ \frac{1}{q_i q_i q_2 \cdots q_\omega} \right]
\]
\[
\left\{ \left[ \frac{1}{q_i} \right] - \sum_{2 \leq j \leq \omega} \left[ \frac{1}{q_i q_j} \right] + \sum_{2 \leq j, k \leq \omega} \left[ \frac{1}{q_i q_j q_k} \right] - \cdots + (-1)^{\omega-1} \left[ \frac{1}{q_i q_2 \cdots q_\omega} \right] \right\}.
\]

Cancelling \( q_i \) within the brackets, the first brace is clearly equal to \(-E_c(q_i)\). In the second brace, as all \( q_j, q_k, \ldots, 2 \leq j, k \leq \omega, \ldots \) divide \( \bar{\nu} \), the numbers within the integral part brackets are integers. We therefore can write it
\[
\bar{\nu} \left( 1 - \sum_{2 \leq j \leq \omega} \frac{1}{q_j} - \sum_{2 \leq j, k \leq \omega} \frac{1}{q_j q_k} + \cdots + (-1)^{\omega-1} \frac{1}{q_2 \cdots q_\omega} \right) = \varphi(\bar{\nu})
\]

Substituting the braces by their found values and taking into account that \( \varphi(\bar{\nu}) = \varphi(c)/(q_i - 1) \), since \( (c, \bar{\nu}) = 1 \), we get
\[
E_c(q_i) = \frac{\varphi(c)}{q_i - 1} - E_{c/q_i}(q_i),
\]
which proves the Lemma.
Lemma 5.
\[ e^{k_1 c} < \prod_{2 \leq p \leq c} p < e^{k_2 c}. \]

**Proof.** This is the multiplicative form of Tchebycheff's estimate for \( \sum_{2 \leq p \leq c} \log p \), namely,
\[ k_1 c < \sum_{2 \leq p \leq c} \log p < k_2 c, \]
for \( c \geq 2 \), with \( k_1, k_2 \) positive absolute constants.

Lemma 6.
\[ e^{-k_3 c} < \prod_{2 \leq p \leq c} p^{\frac{1}{p}} < e^{k_3 c}. \]

**Proof.** This is the multiplicative form of Merten’s estimate for \( \sum_{2 \leq p \leq c} \frac{1}{p} \log p \), namely,
\[ \log c - k_3 < \sum_{2 \leq p \leq c} \frac{1}{p} \log p < \log c + k_3, \]
for \( c \geq 2 \), with \( k_3 \) a positive absolute constant.

We now state a result which gives a lower bound for the geometric mean \( G_{\phi(c)}^e \) in terms of the prime factors \( q_i(c) \) and their exponents \( \alpha_i \).

**Theorem 2.**
\[ G_{\phi(c)}^e > k_4 \prod_{1 \leq i \leq \omega} q_i^{2 \alpha_i - 1 - \frac{2}{\phi(c)}E_e(q_i)} \left( \frac{q_i - 1}{2} \right)^2, \]
where \( k_4 \) is a positive absolute constant.

**Proof.** We transform the expression given for \( G_e \) in Theorem 1, as follows:
\[ G_e = \prod_{1 \leq i \leq \omega} q_i^{\phi(e)} \prod_{2 \leq p < c} q_i^{E_e(p)}, \]
\[ \text{where} \quad \phi(e) \text{ is the Euler's totient function.} \]
Raising this inequality to the power $2$, we have

$$G_c = \prod_{1 \leq i \leq \omega} \frac{q_{i}^{\varphi(c)}}{q_{i}^{\frac{\varphi(c)}{2}}} \prod_{2 \leq p < \frac{\varphi(c)}{2\omega}} p^{E_c(q_i)} \prod_{2 \leq p < c} p^{E_c(p)}.$$ 

Joining the first two products into one and splitting the third product as indicated, we have

$$G_c = \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2}-E_c(q_i)} \prod_{2 \leq p < \frac{\varphi(c)}{2\omega}} p^{E_c(p)} \prod_{\frac{\varphi(c)}{2\omega} \leq p < c} p^{E_c(p)}.$$ 

Applying Lemma 2 to the second and third product and splitting the products in an obvious way, we get successively

$$G_c > \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2}-E_c(q_i)} \left\{ \prod_{2 \leq p < \frac{\varphi(c)}{2\omega}} p^\frac{1}{p^p} \right\} \left\{ \prod_{2 \leq p < \frac{\varphi(c)}{2\omega}} p \right\}^{-2^\omega - 1} \prod_{2 \leq p < c} p.$$ 

Joining the third and the fourth product into one, we have

$$G_c > \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2}-E_c(q_i)} \left\{ \prod_{2 \leq p < \frac{\varphi(c)}{2\omega}} p^\frac{1}{p^p} \right\} ^{\varphi(c)} \left\{ \prod_{2 \leq p < \frac{\varphi(c)}{2\omega}} p \right\}^{-2^\omega - 1} \prod_{2 \leq p < c} p.$$ 

Applying Lemma 6 to the second product, Lemma 5 to the third and fourth product, we have

$$G_c > \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2}-E_c(q_i)} \left\{ \prod_{2 \leq p < \frac{\varphi(c)}{2\omega}} p^\frac{1}{p^p} \right\} ^{\varphi(c)} \left\{ e^{-k_3 \frac{\varphi(c)}{2\omega-1}} \right\}^{\varphi(c)} \left\{ e^{k_2 \frac{\varphi(c)}{2\omega-1}} \right\}^{-2^{\omega - 1} + 1} e^{k_1 c}.$$ 

Summing the exponents of $e$, we have

$$G_c > \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2}-E_c(q_i)} \left( \frac{\varphi(c)}{2\omega-1} \right)^{\varphi(c)} e^{-k_3 \varphi(c) + k_1 c - k_4 \varphi(c) - k_2 \frac{\varphi(c)}{2\omega}}.$$ 

Raising this inequality to the power $\frac{2}{\varphi(c)}$, we get for the geometric mean $G_c^{\frac{2}{\varphi(c)}}$,

$$G_c^{\frac{2}{\varphi(c)}} > \prod_{1 \leq i \leq \omega} q_i^{1 - \frac{2}{\varphi(c)}E_c(q_i)} \left( \frac{\varphi(c)}{2\omega-1} \right)^{\varphi(c)} e^{-2k_3 + 2k_1 \frac{1}{\varphi(c)} - 2k_2 \left( 1 + \frac{1}{2\omega-1} \right)}.$$ 

(3)
Evaluating the second parenthesis, we have
\[
\left( \frac{\varphi(c)}{2^{\omega-1}} \right)^2 = 4 \prod_{1 \leq i \leq \omega} q_i^{2\alpha_i - 2} \left( \frac{q_i - 1}{2} \right)^2.
\]

On the other hand, since \( \frac{c}{\varphi(c)} > 1 \) and \( \left( 1 + \frac{1}{2^{\omega-1}} \right) \leq 2 \), the entire exponent of \( e \) appearing in (3) is \( > -2k_3 + 2k_1 - 4k_2 \). Setting \( k_4 = 4e^{-2k_3+2k_1-4k_2} \), as a new absolute constant and substituting in (3), we finally get
\[
G_{c^{\varphi(c)}}^2 > k_4 \prod_{1 \leq i \leq \omega} q_i^{2\alpha_i - 2 - \frac{2}{\varphi(c)}E_c(q_i)} \left( \frac{q_i - 1}{2} \right)^2,
\]
which was to be proved.

Following main theorem gives a lower bound for the geometric mean \( G_{c^{\varphi(c)}}^2 \) in terms of \( c \) and its radical.

**Theorem 3.** For any given \( \varepsilon > 0 \)
\[
G_{c^{\varphi(c)}}^2 > k_\varepsilon R(c)^{1-\varepsilon} c^2,
\]
where \( k_\varepsilon \) is a positive absolute constant, depending on \( \varepsilon \).

**Proof.** Denote the expressions within the product of theorem 2 by \( F(q_i, \alpha_i) \), \( 1 \leq q_i \leq \omega \). The proof is in three steps. The first step gives a lower bound of \( F(q_i, \alpha_i) \) for \( \alpha_i \geq 2 \). The second step gives a lower bound of \( F(q_i, \alpha_i) \) for \( \alpha_i = 1 \). The third step combines these results to prove the theorem.

**Step 1.** For \( \alpha_i \geq 2 \) we have by Lemma 3
\[
F(q_i, \alpha_i) = q_i^{2\alpha_i - 1 - \frac{2}{\varphi(c)}E_c(q_i)} \left( \frac{q_i - 1}{2} \right)^2
= q_i^{2\alpha_i - 1 - \frac{2}{q_i}} \left( \frac{q_i - 1}{2} \right)^2
= q_i^{2\alpha_i + 1} \left( \frac{1}{q_i^{q_i}} \right)^2 \left( \frac{1}{2} - \frac{1}{2q_i} \right)^2.
\]

Since for \( q_i \geq 2 \) the product \( \left( \frac{1}{q_i^{q_i}} \right)^{-2} \left( \frac{1}{2} - \frac{1}{2q_i} \right)^2 \), increasing monotonically, tends to \( 1/4 \) for \( q_i \rightarrow \infty \), we can write, for any given \( \varepsilon > 0 \)
\[
F(q_i, \alpha_i) > q_i^{2\alpha_i + 1} q_i^{-\varepsilon} = q_i^{2\alpha_i + 1 - \varepsilon},
\]
for all primes greater than $N_\varepsilon$, where $N_\varepsilon$ is a number depending only on $\varepsilon$.

For primes smaller than $N_\varepsilon$, we can write

$$F(q_i, \alpha_i) > q_i^{2\alpha_i+1} \left( \frac{1}{q_i^{\alpha_i/2}} \right)^2 \left( \frac{1}{2} - \frac{1}{2q_i^{\alpha_i/2}} \right)^2 q_i^{-\varepsilon} > \frac{1}{32} q_i^{2\alpha_i+1-\varepsilon},$$

since, as said before, the product $\left( \frac{1}{q_i^{\alpha_i/2}} \right)^2 \left( \frac{1}{2} - \frac{1}{2q_i^{\alpha_i/2}} \right)^2$ is monotonically increasing, and therefore its minimum is at $q_i = 2$, i.e. is equal to $\left( 2^{\frac{1}{2}} \right)^2 \left( \frac{1}{2} - \frac{1}{4} \right)^2 = \frac{1}{32}$.

$N_\varepsilon$ can be calculated. It is the abscissa where the two curves $y = \left( x^{\frac{1}{x}} \right)^{-2} \left( \frac{1}{2} - \frac{1}{2x} \right)^2$ and $y = x^{-\varepsilon}$ cut each other. Consequently it is the positive root of the equation

$$x - 1 = 2x^{\frac{1}{x} + \frac{2-\varepsilon}{2}},$$

which results after setting

$$\left( x^{\frac{1}{x}} \right)^{-2} \left( \frac{1}{2} - \frac{1}{2x} \right)^2 = x^{-\varepsilon}.$$

By elementary analysis $N_\varepsilon \to \infty$ for $\varepsilon \to 0$.

**Step 2.** For $\alpha_i = 1$ we have by Lemma 4 and Lemma 1

$$F(q_i, \alpha_i) = \frac{2^{\alpha_i-1}}{q_i} \frac{E_{c/\varepsilon}(q_i)}{\phi(q_i)} \left( \frac{1}{q_i^{\alpha_i/2}} \right)^2 = \frac{2^{\alpha_i-1}}{q_i} \frac{\phi(q_i)}{\phi(q_i)} \left( \frac{1}{q_i^{\alpha_i/2}} \right)^2 = \frac{2^{\alpha_i-1}}{q_i^{\alpha_i-1+\phi(q_i)/\phi(q_i)}} \left( \frac{1}{q_i^{\alpha_i/2}} \right)^2 = \frac{2^{\alpha_i-1}}{q_i^{\alpha_i-1}} \left( \frac{1}{2} - \frac{1}{2q_i^{\alpha_i/2}} \right)^2.$$  

Since for $q_i \geq 2$ the product $\left( \frac{1}{q_i^{\alpha_i/2}} \right)^2 \left( \frac{1}{2} - \frac{1}{2q_i^{\alpha_i/2}} \right)^2$, increasing monotonically, tends to $\frac{1}{4}$ for $q_i \to \infty$, we can write

$$F(q_i, \alpha_i) > q_i^{2\alpha_i+1-\varepsilon} = q_i^{3-\varepsilon},$$

for all primes greater than $M_\varepsilon$, where $M_\varepsilon$ is a certain number depending only on $\varepsilon$.

For primes smaller than $M_\varepsilon$ we can write
\[ F(q_i, \alpha_i) > q_i^{2\alpha_i+1} \left( \frac{1}{q_i^{\alpha_i-1}} \right)^{-2} \left( \frac{1}{2} - \frac{1}{2q_i} \right)^2 q_i^{-\varepsilon} \]

since the product \( \left( \frac{1}{q_i^{\alpha_i-1}} \right)^{-2} \left( \frac{1}{2} - \frac{1}{2q_i} \right)^2 \) is monotonically increasing, and therefore its minimum is at \( q_i = 2 \), i.e. is equal to \( (2^{-2}) \left( \frac{1}{2} - \frac{1}{4} \right)^2 = \frac{1}{64} \).

\( M_\varepsilon \) can be calculated as a function of \( \varepsilon \). It is the abscissa where the two curves \( y = \left( \frac{1}{x^{x-1}} \right)^{-2} \left( \frac{1}{2} - \frac{1}{2x} \right)^2 \) and \( y = x^{-\varepsilon} \) cut each other. It is therefore the positive root of the equation

\[ x - 1 = 2x^\frac{1}{x-1} + \frac{3}{2^e} \]

which results after setting

\[ \left( \frac{1}{x^{x-1}} \right)^{-2} \left( \frac{1}{2} - \frac{1}{2x} \right)^2 = x^{-\varepsilon}. \]

By elementary analysis \( M_\varepsilon \to \infty \) for \( \varepsilon \to 0 \).

Step 3. Let \( p \) run through the primes \( q_i, 1 \leq i \leq \omega \) of \( c \), and denote by \( D(p) \) the corresponding exponents \( \alpha_i \).

All the integers \( q_i^{\alpha_i}, 1 \leq i \leq \omega \), fall into one of the following, mutually exclusive, classes specified under Steps 1 and Step 2, namely

\[
\begin{align*}
2 & \leq p \leq [N_\varepsilon] & D(p) & \geq 2 & \omega_1(\varepsilon) \\
[N_\varepsilon] + 1 & \leq p & D(p) & \geq 2 & \omega_2(\varepsilon, c) \\
2 & \leq p \leq [M_\varepsilon] & D(p) & = 1 & \omega_3(\varepsilon) \\
[M_\varepsilon] + 1 & \leq p & D(p) & = 1 & \omega_4(\varepsilon, c).
\end{align*}
\]

It is clear from their definition that

\[
\begin{align*}
\omega_1(\varepsilon) & < \pi(N_\varepsilon) \\
\omega_3(\varepsilon) & < \pi(M_\varepsilon)
\end{align*}
\]

where \( \pi(x) \) denotes the number of primes not exceeding \( x \).
As indicated $\omega_2$ and $\omega_4$ depend on both $\varepsilon$ and $c$.

Accordingly, the product $\prod_{1 \leq i \leq \omega} F(q_i, \alpha_i)$ extended over above classes can be written

\[ \prod_{1 \leq i \leq \omega} F(q_i, \alpha_i) = \prod_{2 \leq p < [N_c]} F(p, D(p)) \prod_{[N_c]+1 \leq p \atop D(p) \geq 2} F(p, D(p)) \prod_{2 \leq p \leq [M_c]} F(p, D(p)) \prod_{[M_c]+1 \leq p \atop D(p) = 1} F(p, D(p)). \]

Applying to these four products the lower bounds found in Step 1 and Step 2 for the respective expressions $F(q_i, \alpha_i)$, we obtain

\[ \prod_{1 \leq i \leq \omega} F(q_i, \alpha_i) > \frac{1}{32^{\omega_1(\varepsilon)}} \prod_{2 \leq p < [N_c]} p^{2D(p) + 1 - \varepsilon} \prod_{[N_c]+1 \leq p \atop D(p) \geq 2} p^{2D(p) + 1 - \varepsilon} \prod_{2 \leq p \leq [M_c]} p^{2D(p) + 1 - \varepsilon} \prod_{[M_c]+1 \leq p \atop D(p) = 1} p^{2D(p) + 1 - \varepsilon}. \]

Since, as said above, the four classes cover, by definition, the whole range of the integers $q_i^{\alpha_i}, 1 \leq i \leq \omega$, this inequality can be written

\[ \prod_{1 \leq i \leq \omega} F(q_i, \alpha_i) > \frac{1}{2^{5\omega_1(\varepsilon) + 6\omega_3(\varepsilon)}} \prod_{1 \leq i \leq \omega} q_i^{2\alpha_i + 1 - \varepsilon} = \frac{1}{2^{5\omega_1(\varepsilon) + 6\omega_3(\varepsilon)}} R(c)^{1-\varepsilon} c^2. \]

By Theorem 2 we therefore have

\[ G_{\varepsilon}^{\frac{2}{\varphi(c)}} = k_4 \prod_{1 \leq i \leq \omega} F(q_i, \alpha_i) > \frac{k_4}{2^{5\omega_1(\varepsilon) + 6\omega_3(\varepsilon)}} R(c)^{1-\varepsilon} c^2 \]

\[ > \frac{k_4}{2^{5\pi(N_c) + 6\pi(M_c)}} R(c)^{1-\varepsilon} c^2 \]

Setting $\frac{k_4}{2^{5\pi(N_c) + 6\pi(M_c)}}$ as an absolute constant depending on $\varepsilon$, we finally get

\[ G_{\varepsilon}^{\frac{2}{\varphi(c)}} > k_\varepsilon R(c)^{1-\varepsilon} c^2, \]

as claimed by Theorem 3.

From above theorem results immediately
Theorem 4. For any positive integer there are partitions $c = a + b$, with positive coprime integers $a$ and $b$, such that

$$k_\varepsilon R(c)^{1-\varepsilon}c^2 < R(abc).$$

Proof. Because of Theorem 3, all radicals of equations (1) which are greater than $G_{2^2\varphi(c)}^c$ satisfy a fortiori the condition of Theorem 4.

For said partitions this is a substantially stronger result than the $abc$-conjecture

$$\kappa_\varepsilon c^{1+\varepsilon} < R(abc), \quad \varepsilon > 0.$$

We shall now obtain an upper bound for $G_{2^2\varphi(c)}^c$. This will depend on $\omega$, the number of prime factors of $c$. To this end we prove following

Theorem 5.

$$G_{2^2\varphi(c)}^c < k_5 k_6^\omega R(c)^2,$$

where $k_5 > 0$ and $k_6 > 1$ are absolute constants.

Proof. Applying Lemma 1, Lemma 5 and Lemma 6, we get successively

$$G_c = R(c)^{\varphi(c)/2} \prod_{2\leq p \leq c} p^{E_c(p)}$$

by Theorem 1

$$= \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2} - E_c(q_i)} \prod_{2 \leq p \leq c} p^{E_c(p)}$$

by Lemma 1

$$< \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2} - E_c(q_i)} \left\{ \prod_{2 \leq p \leq c} p^{\varphi(c)} \left( \prod_{2 \leq p \leq c} p \right)^{2^\omega - 1} \right\}$$

by Lemma 5, 6

$$< e^{k_3\varphi(c) + k_2 2^\omega - 1} c^{\varphi(c)} \prod_{1 \leq i \leq \omega} q_i^{\frac{\varphi(c)}{2} - E_c(q_i)}.$$ 

Raising the last inequality to the power $\frac{2}{\varphi(c)}$ we have

$$G_c^{2^{\frac{1}{\varphi(c)}}} < e^{2 k_3 + k_2 2^\omega - \frac{2}{\varphi(c)}} c^2 \prod_{1 \leq i \leq \omega} q_i^{1 - \frac{2}{\varphi(c)}E_c(q_i)}.$$ 

13
\[
\frac{2q_i}{q_i - 1} \leq 3 \text{ for all } q_i \geq 3 \text{ and } \frac{2q_i}{q_i - 1} = 4 \text{ for } q_i = 2,
\]
we have
\[
2^\omega \frac{c}{\varphi(c)} = \prod_{1 \leq i \leq \omega} \frac{2q_i}{q_i - 1} < 2 \cdot 3^\omega.
\]

Hence
\[
G_c^2 \varphi(c) < e^{2k_3 + 2k_2 3^\omega} c^2 \prod_{1 \leq i \leq \omega} q_i^{1 - \frac{2}{\varphi(c)} E(c(q_i))}
\]
\[
< e^{2k_3 + 2k_2 3^\omega} c^2 \prod_{1 \leq i \leq \omega} q_i.
\]

Setting \(k_5 = e^{2k_3}\) and \(k_6 = e^{2k_2}\) as absolute constants, we obtain
\[
G_c^2 \varphi(c) < k_5 k_6 3^\omega R(c) c^2,
\]
as required.

\textbf{Remark.} Combining Theorem 4 and Theorem 5 we have
\[
k_\varepsilon R(c)^{1-\varepsilon} c^2 < G_c^2 \varphi(c) < k_5 k_6 3^\omega R(c) c^2,
\]
and dividing by \(R(c)c^2\) we get
\[
k_\varepsilon R(c)^{-\varepsilon} < \frac{G_c^2 \varphi(c)}{R(c)c^2} < k_5 k_6 3^\omega.
\]
Letting \(c\) run through the numbers \(c_x = q_1^{x_1} \cdots q_\omega^{x_\omega}, 1 \leq x_i < \infty\), which all have the same radical \(R(c) = R\) we have
\[
k_\varepsilon R^{-\varepsilon} \leq \liminf_{1 \leq x_i < \infty} \frac{G_c^2 \varphi(c_x)}{R c_x^2} \leq \limsup_{1 \leq x_i < \infty} \frac{G_c^2 \varphi(c_x)}{R c_x^2} \leq k_5 k_6 3^\omega.
\]
