A deep quench approach
to the optimal control
of an Allen-Cahn equation
with dynamic boundary condition
and double obstacle potentials

Pierluigi Colli\(^1\), M. Hassan Farshbaf-Shaker\(^2\) and Jürgen Sprekels\(^2\)

Abstract

In this paper, we investigate optimal control problems for Allen-Cahn variational inequalities with a dynamic boundary condition involving double obstacle potentials and the Laplace-Beltrami operator. The approach covers both the cases of distributed controls and of boundary controls. The cost functional is of standard tracking type, and box constraints for the controls are prescribed. We prove existence of optimal controls and derive first-order necessary conditions of optimality. The general strategy is the following: we use the results that were recently established by two of the authors in the paper \([5]\) for the case of (differentiable) logarithmic potentials and perform a so-called “deep quench limit”. Using compactness and monotonicity arguments, it is shown that this strategy leads to the desired first-order necessary optimality conditions for the case of (non-differentiable) double obstacle potentials.

1 Introduction

Let \( \Omega \subset \mathbb{R}^N \), \( 2 \leq N \leq 3 \), denote some open and bounded domain with smooth boundary \( \Gamma \) and outward unit normal \( n \), and let \( T > 0 \) be a given final time. We put \( Q := \Omega \times (0,T) \)

and \( \Sigma := \Gamma \times (0, T) \). Moreover, we introduce the function spaces
\[
H := L^2(\Omega), \quad V := H^1(\Omega), \quad H_\Gamma := L^2(\Gamma), \quad V_\Gamma := H^1(\Gamma),
\]
\[
\mathcal{H} := L^2(Q) \times L^2(\Sigma), \quad \mathcal{X} := L^\infty(Q) \times L^\infty(\Sigma),
\]
\[
\mathcal{Y} := \{(y, y_\Gamma) : y \in H^1(0, T; H) \cap C^0([0, T]; V) \cap L^2(0, T; H^2(\Omega)),
\quad y_\Gamma \in H^1(0, T; H_\Gamma) \cap C^0([0, T]; V_\Gamma) \cap L^2(0, T; H^2(\Gamma)), \quad y_\Gamma = y |_{\Gamma} \}, \quad (1.1)
\]
which are Banach spaces when endowed with their natural norms. In the following, we denote the norm in a Banach space \( E \) by \( \| \cdot \|_E \); for convenience, the norm of the space \( H^N \) will also be denoted by \( \| \cdot \|_H \). Identifying \( H \) with its dual space \( H^* \), we have the Hilbert triplet \( V \subset H \subset V^* \), with dense and compact embeddings. Analogously, we obtain the triplet \( V_\Gamma \subset H_\Gamma \subset V_\Gamma^* \), with dense and compact embeddings.

We assume that \( \beta_i \geq 0, \; 1 \leq i \leq 5 \), are given constants which do not all vanish. Moreover, we assume:

(A1) There are given functions
\[
z_Q \in L^2(Q), \quad z_\Sigma \in L^2(\Sigma), \quad z_T \in H^1(\Omega), \quad z_{\Gamma, T} \in H^1(\Gamma),
\]
\[
\tilde{u}_1, \tilde{u}_2 \in L^\infty(Q) \text{ with } \tilde{u}_1 \leq \tilde{u}_2 \text{ a.e. in } Q,
\]
\[
\tilde{u}_{1}\Gamma, \tilde{u}_{2}\Gamma \in L^\infty(\Sigma) \text{ with } \tilde{u}_{1}\Gamma \leq \tilde{u}_{2}\Gamma \text{ a.e. in } \Sigma.
\]

Then, defining the tracking type objective functional
\[
J((y, y_\Gamma), (u, u_\Gamma)) := \frac{\beta_1}{2} \int_0^T \int_\Omega |y - z_Q|^2 \, dx \, dt + \frac{\beta_2}{2} \int_0^T \int_\Gamma |y_\Gamma - z_\Sigma|^2 \, d\Gamma \, dt
\]
\[
+ \frac{\beta_3}{2} \int_\Omega |y(\cdot, T) - z_T|^2 \, dx + \frac{\beta_3}{2} \int_\Gamma |y_\Gamma(\cdot, T) - z_{\Gamma, T}|^2 \, d\Gamma
\]
\[
+ \frac{\beta_4}{2} \int_0^T \int_\Omega |u|^2 \, dx \, dt + \frac{\beta_5}{2} \int_0^T \int_\Gamma |u_\Gamma|^2 \, d\Gamma \, dt, \quad (1.2)
\]
as well as the parabolic initial-boundary value problem with nonlinear dynamic boundary condition
\[
\partial_t y - \Delta y + \xi + f'(y) = u \quad \text{a.e. in } Q, \quad (1.3)
\]
\[
y_\Gamma = y |_{\Gamma}, \quad \partial_\nu y + \partial_\nu y_\Gamma - \Delta_\Gamma y_\Gamma + \xi_\Gamma + g'(y_\Gamma) = u_\Gamma \quad \text{a.e. on } \Sigma, \quad (1.4)
\]
\[
\xi \in \partial I_{[-1,1]}(y) \quad \text{a.e. in } Q, \quad \xi_\Gamma \in \partial I_{[-1,1]}(y_\Gamma) \quad \text{a.e. on } \Sigma, \quad (1.5)
\]
\[
y(\cdot, 0) = y_0 \quad \text{a.e. in } \Omega, \quad y_\Gamma(\cdot, 0) = y_{0}\Gamma \quad \text{a.e. on } \Gamma, \quad (1.6)
\]
and the admissible set for the control variables
\[
\mathcal{U}_{ad} := \{(u, u_\Gamma) \in L^2(Q) \times L^2(\Sigma) : \tilde{u}_1 \leq u \leq \tilde{u}_2 \quad \text{a.e. in } Q,
\quad \tilde{u}_{1}\Gamma \leq u_\Gamma \leq \tilde{u}_{2}\Gamma \quad \text{a.e. in } \Sigma \}, \quad (1.7)
\]
our overall optimization problem reads as follows:

\[ (P_0) \quad \text{Minimize } J((y, y_\Gamma), (u, u_\Gamma)) \text{ over } Y \times U_{ad} \text{ subject to the condition that (1.3)--(1.6) be satisfied.} \quad (1.8) \]

In (1.6), \( y_0 \) and \( y_0 \Gamma \) are given initial data with \( y_0 \big| \Gamma = y_0 \Gamma \), where the trace \( y \Gamma \) (if it exists) of a function \( y \) on \( \Gamma \) will in the following be denoted by \( y_\Gamma \) without further comment. Moreover, \( \Delta \Gamma \) is the Laplace-Beltrami operator on \( \Gamma \), \( \partial_n \) denotes the outward normal derivative, and the functions \( f_2, g_2 \) are given smooth nonlinearities, while \( u \) and \( u_\Gamma \) play the roles of distributed or boundary controls, respectively. Note that we do not require \( u_\Gamma \) to be somehow the restriction of \( u \) on \( \Gamma \); such a requirement would be much too restrictive for a control to satisfy.

We remark at this place that for the cost functional to be meaningful it would suffice to only assume that \( z_T \in L^2(\Omega) \) and \( z_\Gamma, T \in L^2(\Gamma) \). However, the higher regularity of \( z_T \) and \( z_\Gamma, T \) requested in (A1) will later be essential to be able to treat the adjoint state problem.

The system (1.3)--(1.6) is an initial-boundary value problem with nonlinear dynamic boundary condition for an Allen-Cahn differential inclusion, which, under appropriate conditions on the data (cf. Section 2), admits for every \((u, u_\Gamma) \in U_{ad}\) a unique solution \((y, y_\Gamma, \xi, \xi_\Gamma) \in Y \times H\). Hence, the solution operator \( S_0 : U_{ad} \to Y, (u, u_\Gamma) \mapsto (y, y_\Gamma) \), is well defined, and the control problem \((P_0)\) is equivalent to minimizing the reduced cost functional

\[ J_{\text{red}}((u, u_\Gamma)) := J(S_0(u, u_\Gamma)), (u, u_\Gamma) \]

over \( U_{ad} \).

In the physical interpretation, the unknown \( y \) usually stands for the order parameter of an isothermal phase transition, typically a rescaled fraction of one of the involved phases. In such a situation it is physically meaningful to require \( y \) to attain values in the interval \([-1, 1]\) on both \( \Omega \) and \( \Gamma \). A standard technique to meet this requirement is to use the indicator function \( I_{[-1,1]} \) of the interval \([-1, 1] \), so that the bulk and surface potentials \( I_{[-1,1]} + f_2 \) and \( I_{[-1,1]} + g_2 \) become double obstacle, and the subdifferential \( \partial I_{[-1,1]} \), defined by

\[
\eta \in \partial I_{[-1,1]}(v) \quad \text{if and only if} \quad \eta \begin{cases} 
\leq 0 & \text{if } v = -1 \\
= 0 & \text{if } -1 < v < 1 \\
\geq 0 & \text{if } v = 1 
\end{cases}
\]

is employed in place of the usual derivative. Concerning the selections \( \xi, \xi_\Gamma \) in (1.5), one has to keep in mind that \( \xi \) may be not regular enough as to single out its trace on the boundary \( \Gamma \), and if the trace \( \xi_\Gamma \) exists, it may differ from \( \xi_\Gamma \), in general.

The optimization problem \((P_0)\) belongs to the problem class of so-called MPECs (Mathematical Programs with Equilibrium Constraints). It is a well-known fact that the differential inclusion conditions (1.3)--(1.5) occurring as constraints in \((P_0)\) violate all of the known classical NLP (nonlinear programming) constraint qualifications. Hence, the existence of Lagrange multipliers cannot be inferred from standard theory, and the derivation...
of first-order necessary condition becomes very difficult, as the treatments in [6, 7, 8, 9] for the case of standard Neumann boundary conditions show (note that [9] deals with the more difficult case of the Cahn-Hilliard equation).

The approach in the abovementioned papers was based on penalization as approximation technique. Here, in the more difficult case of a dynamic boundary condition of the form (1.14), we use an entirely different approximation strategy which is usually referred to in the literature as the “deep quench limit”: we replace the inclusion conditions (1.5) by

$$\xi = \varphi(\alpha) h'(y), \quad \xi_\Gamma = \psi(\alpha) h'(y), \quad (1.10)$$

with real-valued functions $\varphi, \psi$ that are continuous and positive on $(0,1]$ and satisfy $\varphi(\alpha) = \psi(\alpha) = o(\alpha)$ as $\alpha \searrow 0$ and $\varphi(\alpha) \leq C_{\varphi\psi} \psi(\alpha)$ for some $C_{\varphi\psi} > 0$, and where

$$h(r) = \begin{cases} (1-r) \ln(1-r) + (1+r) \ln(1+r) & \text{if } r \in (-1,1), \\ 2 \ln 2 & \text{if } r \in \{-1,1\} \end{cases} \quad (1.11)$$

is the standard convex logarithmic potential. We remark that we could simply choose $\varphi(\alpha) = \psi(\alpha) = \alpha^p$ for some $p > 0$; however, there might be situations (e.g., in the numerical approximation) in which it is advantageous to let $\varphi$ and $\psi$ have a different behavior as $\alpha \searrow 0$.

Now observe that $h'(y) = \ln \left( \frac{1+y}{1-y} \right)$ and $h''(y) = \frac{2}{1-y^2} > 0$ for $y \in (-1,1)$. Hence, in particular, we have

$$\lim_{\alpha \searrow 0} \varphi(\alpha) h'(y) = 0 \quad \text{for } -1 < y < 1,$$

$$\lim_{\alpha \searrow 0} \left( \varphi(\alpha) \lim_{y \rightarrow 1} h'(y) \right) = -\infty, \quad \lim_{\alpha \searrow 0} \left( \varphi(\alpha) \lim_{y \rightarrow -1} h'(y) \right) = +\infty. \quad (1.12)$$

Since similar relations hold if $\varphi$ is replaced by $\psi$, we may regard the graphs of the functions $\varphi(\alpha) h'$ and $\psi(\alpha) h'$ as approximations to the graph of the subdifferential $\partial I_{[-1,1]}$.

Now, for any $\alpha > 0$ the optimal control problem (later to be denoted by $(P_\alpha)$), which results if in $(P_0)$ the relation (1.5) is replaced by (1.10), is of the type for which in [5] the existence of optimal controls $(u^\alpha, u_{\Gamma}^\alpha) \in \mathcal{U}_{ad}$ as well as first-order necessary and second-order sufficient optimality conditions have been derived. Proving a priori estimates (uniform in $\alpha > 0$), and employing compactness and monotonicity arguments, we will be able to show the following existence and approximation result: whenever $\{(u^\alpha_n, u_{\Gamma n})\} \subset \mathcal{U}_{ad}$ is a sequence of optimal controls for $(P_{\alpha_n})$, where $\alpha_n \searrow 0$ as $n \rightarrow \infty$, then there exist a subsequence of $\{\alpha_n\}$, which is again indexed by $n$, and an optimal control $(\bar{u}, \bar{u}_\Gamma) \in \mathcal{U}_{ad}$ of $(P_0)$ such that

$$(u^\alpha_n, u_{\Gamma n}) \rightarrow (\bar{u}, \bar{u}_\Gamma) \quad \text{weakly-star in } \mathcal{X} \quad \text{as } n \rightarrow \infty. \quad (1.13)$$

In other words, optimal controls for $(P_\alpha)$ are for small $\alpha > 0$ likely to be “close” to optimal controls for $(P_0)$. It is natural to ask if the reverse holds, i.e., whether every optimal control for $(P_0)$ can be approximated by a sequence $\{(u^\alpha_n, u_{\Gamma n}^\alpha)\}$ of optimal controls for $(P_{\alpha_n})$ for some sequence $\alpha_n \searrow 0$. 

Unfortunately, we will not be able to prove such a “global” result that applies to all optimal controls for \((P_0)\). However, a “local” result can be established. To this end, let \((\bar{u}, \bar{u}_\Gamma) \in U_{ad}\) be any optimal control for \((P_0)\). We introduce the “adapted” cost functional

\[
\tilde{J}((y, y_\Gamma), (u, u_\Gamma)) := J((y, y_\Gamma), (u, u_\Gamma)) + \frac{1}{2} \|u - \bar{u}\|^2_{L^2(Q)} + \frac{1}{2} \|u_\Gamma - \bar{u}_\Gamma\|^2_{L^2(\Sigma)}
\]  

(1.14)

and consider for every \(\alpha \in (0, 1]\) the “adapted control problem” of minimizing \(\tilde{J}\) over \(\mathcal{Y} \times U_{ad}\) subject to the constraint that \((y, y_\Gamma)\) solves the approximating system \((1.3), (1.4), (1.6), (1.10)\). It will then turn out that the following is true:

(i) There are some sequence \(\alpha_n \searrow 0\) and minimizers \((\bar{u}^{\alpha_n}, \bar{u}^{\alpha_n}_\Gamma) \in U_{ad}\) of the adapted control problem associated with \(\alpha_n, n \in \mathbb{N}\), such that

\[
(\bar{u}^{\alpha_n}, \bar{u}^{\alpha_n}_\Gamma) \rightarrow (\bar{u}, \bar{u}_\Gamma) \text{ strongly in } \mathcal{H} \text{ as } n \rightarrow \infty.
\]  

(1.15)

(ii) It is possible to pass to the limit as \(\alpha \searrow 0\) in the first-order necessary optimality conditions corresponding to the adapted control problems associated with \(\alpha \in (0, 1]\) in order to derive first-order necessary optimality conditions for problem \((P_0)\).

The paper is organized as follows: in Section 2, we give a precise statement of the problem under investigation, and we derive some results concerning the state system \((1.3)-(1.6)\) and its \(\alpha\)-approximation which is obtained if in \((P_0)\) the relation \((1.5)\) is replaced by the relations \((1.10)\). In Section 3, we then prove the existence of optimal controls and the approximation result formulated above in (i). The final Section 4 is devoted to the derivation of the first-order necessary optimality conditions, where the strategy outlined in (ii) is employed.

During the course of this analysis, we will make repeated use of the elementary Young’s inequality

\[
a b \leq \gamma |a|^2 + \frac{1}{4\gamma} |b|^2 \quad \forall a, b \in \mathbb{R} \quad \forall \gamma > 0,
\]

of Hölder’s inequality, and of the fact that we have the continuous embeddings \(H^1(\Omega) \subset L^p(\Omega)\), for \(1 \leq p \leq 6\), and \(H^2(\Omega) \subset L^\infty(\Omega)\) in three dimensions of space. In particular, we have

\[
\|v\|_{L^p(\Omega)} \leq \tilde{C}_p \|v\|_{H^1(\Omega)} \quad \forall v \in H^1(\Omega),
\]

(1.16)

\[
\|v\|_{L^\infty(\Omega)} \leq \tilde{C}_\infty \|v\|_{H^2(\Omega)} \quad \forall v \in H^2(\Omega),
\]

(1.17)

with positive constants \(\tilde{C}_p, p \in [1,6] \cup \{\infty\}\), that only depend on \(\Omega\).

2 General assumptions and the state equations

In this section, we formulate the general assumptions of the paper, and we state some preparatory results for the state system \((1.3)-(1.6)\) and its \(\alpha\)-approximations. To begin with, we make the following general assumptions:
Definition 2.1: A quadruplet \((y, y_t, \xi, \xi_t) \in \mathcal{Y} \times \mathcal{H}\) is called a solution to (1.3)–(1.6) if we have \(\xi \in \partial I_{[-1,1]}(y)\) a.e. in \(Q\), \(\xi_t \in \partial I_{[-1,1]}(y_t)\) a.e. on \(\Sigma\), \(y(0) = y_0\), \(y_t(0) = y_{0t}\), and, for almost every \(t \in (0,T)\),

\[
\begin{align*}
\int_\Omega \partial_t y(t) \varrho \, dx + \int_\Omega \nabla y(t) \cdot \nabla \varrho \, dx + \int_\Omega (\xi(t) + f_2'(y(t))) \varrho \, dx \\
+ \int_\Gamma \partial_t y_t(t) z_t \, d\Gamma + \int_\Gamma \nabla y_t(t) \cdot \nabla z_t \, d\Gamma + \int_\Gamma (\xi_t(t) + g_2'(y_t(t))) z_t \, d\Gamma \\
= \int_\Omega u(t) \varrho \, dx + \int_\Gamma u_t(t) z_t \, d\Gamma
\end{align*}
\]

for every \(\varrho \in \mathcal{V} = \{ \varrho \in \mathcal{V} : \varrho|_\Gamma = z_t \in V_\Gamma \}\), \((2.3)\)

The following result follows as a special case from [4] Theorems 2.3–2.5 and Remark 4.5] if one puts (in the notation of [4]) \(\beta = \beta_t = \partial I_{[-1,1]}\), \(\pi = f_2\), \(\pi_t = g_2\) there.

Proposition 2.2: Assume that (A2)–(A3) are fulfilled. Then there exists for any \((u, u_t) \in \mathcal{H}\) a unique quadruplet \((y, y_t, \xi, \xi_t) \in \mathcal{Y} \times \mathcal{H}\) solving problem (1.3)–(1.6) in the sense of Definition 2.1.

As in the Introduction, we denote the solution operator of the mapping \((u, u_t) \in \mathcal{H} \mapsto (y, y_t) \in \mathcal{Y}\) by \(S_0\).

We now turn our attention to the approximating state equations. As announced in the Introduction, we choose a special approximation of (1.3)–(1.6); namely, for \(\alpha \in (0,1]\) we consider the system

\[
\begin{align*}
\partial_t y^\alpha - \Delta y^\alpha + \varphi(\alpha) h'(y^\alpha) + f_2'(y^\alpha) = u & \quad \text{a.e. in } Q, \quad (2.4) \\
y_t^\alpha = y_{0t}^\alpha, \quad \partial_t y_t^\alpha + \Delta y_t^\alpha + \psi(\alpha) h'(y_t^\alpha) + g_2'(y_t^\alpha) = u_t & \quad \text{a.e. on } \Sigma, \quad (2.5)
\end{align*}
\]
\[ y^\alpha(\cdot, 0) = y_0^\alpha \quad \text{a.e. in } \Omega, \quad y_1^\alpha(\cdot, 0) = y_0^\alpha \quad \text{a.e. on } \Gamma. \] (2.6)

Here, \( h' \) denotes the derivative, existing in the open interval \((-1, 1)\), of the potential \( h \) defined by \( 1.11 \). Moreover, \( \varphi \) and \( \psi \) are continuous functions on \((0, 1]\) such that

\[ 0 < \varphi(\alpha) \leq 1, \quad 0 < \psi(\alpha) \leq 1, \quad \forall \alpha \in (0, 1], \] (2.7)

\[ \lim_{\alpha \searrow 0} \varphi(\alpha) = \lim_{\alpha \searrow 0} \psi(\alpha) = 0, \] (2.8)

\[ \exists C_{\varphi \psi} > 0 \text{ such that } \varphi(\alpha) \leq C_{\varphi \psi} \psi(\alpha) \quad \forall \alpha \in (0, 1]. \] (2.9)

Of course, for any \( \alpha \in (0, 1] \) it follows that

\[ |\varphi(\alpha) h'(r)| \leq C_{\varphi \psi} |\psi(\alpha) h'(r)| \quad \forall r \in (-1, 1), \] (2.10)

and this implies that the crucial growth condition \((2.3)\) in \([5]\) (see also \([4]\) assumptions \((2.22)-(2.23)\)) is satisfied. Finally, let \( \{(y_0^\alpha, y_0^{\alpha r})\} \) denote a family of approximating data such that

\[ (y_0^\alpha, y_0^{\alpha r}) \in V \times V_T, \quad y_0^{\alpha r} = y_0^\alpha \quad \text{a.e. on } \Gamma, \quad \forall \alpha \in (0, 1], \] (2.11)

\[ |y_0^\alpha| < 1 \quad \text{a.e. in } \Omega, \quad |y_0^{\alpha r}| < 1 \quad \text{a.e. on } \Gamma, \quad \forall \alpha \in (0, 1], \] (2.12)

\[ (y_0^\alpha, y_0^{\alpha r}) \to (y_0, y_0^{\alpha r}) \quad \text{in } V \times V_T \quad \text{as } \alpha \searrow 0. \] (2.13)

In view of \((A3)\) it is straightforward to construct such an approximating family, for instance by truncating \((y_0, y_0^{\alpha r})\) to the levels \(-1 + \alpha\) below and \(1 - \alpha\) above. Now, following the lines of \([5]\), we can state the following lemma.

**Lemma 2.3:** Assume that \((A2)-(A3)\) and \((2.7)-(2.13)\) are fulfilled, and let \( \alpha \in (0, 1] \) be given. Then we have:

(i) The state system \((2.4)-(2.6)\) has for any pair \((u, u_T) \in H\) a unique solution \((y^\alpha, y_1^\alpha) \in Y\) such that

\[ |y^\alpha| < 1 \quad \text{a.e. in } Q, \quad |y_1^\alpha| < 1 \quad \text{a.e. on } \Sigma. \]

(ii) Suppose that also assumption \((A4)\) is satisfied, and suppose that it holds

\[ -1 < \text{ess inf}_{x \in \Omega} y_0^\alpha(x), \quad \text{ess sup}_{x \in \Omega} y_0^\alpha(x) < 1, \] (2.14)

\[ -1 < \text{ess inf}_{x \in \Gamma} y_0^{\alpha r}(x), \quad \text{ess sup}_{x \in \Gamma} y_0^{\alpha r}(x) < 1. \] (2.15)

Then there are constants \(-1 < r_*(\alpha) \leq r^*(\alpha) < 1\), which only depend on \(\Omega, T, y_0^\alpha, y_0^{\alpha r}, f_2, g_2, R\) and \(\alpha\), such that we have: whenever \((y^\alpha, y_1^\alpha) \in Y\) is the unique solution to the state system \((2.4)-(2.6)\) for some \((u, u_T) \in U\), then it holds

\[ r_*(\alpha) \leq y^\alpha \leq r^*(\alpha) \quad \text{a.e. in } Q, \quad r_*(\alpha) \leq y_1^\alpha \leq r^*(\alpha) \quad \text{a.e. in } \Sigma. \] (2.16)

(iii) Suppose that the assumptions in (ii) hold true. Then there is a constant \(K_1^*(\alpha) > 0\), which only depends on \(\Omega, T, f_2, g_2, R\), and \(\alpha\), such that the following holds: whenever
\((u_1, u_{1T}), (u_2, u_{2T}) \in \mathcal{U}\) are given and \((y_1^\alpha, y_{1T}^\alpha), (y_2^\alpha, y_{2T}^\alpha) \in \mathcal{Y}\) are the associated solutions to the state system \((2.4)-(2.6)\), then we have

\[
\|(y_1^\alpha, y_{1T}^\alpha) - (y_2^\alpha, y_{2T}^\alpha)\|_\mathcal{Y} \leq K_1^\alpha \|(u_1, u_{1T}) - (u_2, u_{2T})\|_\mathcal{H}. \tag{2.17}
\]

**Proof:** See \[5\] Theorem 2.1 and Remarks 2.3–2.4.

**Remark 2.4:** It follows from Lemma 2.3, in particular, that the control-to-state mapping

\[
\mathcal{S}_\alpha : \mathcal{X} \to \mathcal{Y}, \quad (u, u_T) \mapsto \mathcal{S}_\alpha(u, u_T) := (y^\alpha, y_T^\alpha), \tag{2.18}
\]

is well defined; moreover, \(\mathcal{S}_\alpha\) is Lipschitz continuous when viewed as a mapping from the subset \(\mathcal{U}\) of \(\mathcal{H}\) into the space \(\mathcal{Y}\).

The next step is to prove a priori estimates uniformly in \(\alpha \in (0, 1]\) for the solution \((y^\alpha, y_T^\alpha) \in \mathcal{Y}\) of \((2.4)-(2.6)\). We have the following result.

**Lemma 2.5:** Suppose that \((A2)-(A4)\) and \((2.7)-(2.15)\) are satisfied. Then there is a constant \(K_2^\alpha > 0\), which only depends on \(\Omega\), \(T\), \(f_2\), \(g_2\), and \(R\), such that we have: whenever \((y^\alpha, y_T^\alpha) \in \mathcal{Y}\) is the solution to \((2.4)-(2.6)\) for some \((u, u_T) \in \mathcal{U}\) and some \(\alpha \in (0, 1]\), then it holds

\[
\|(y^\alpha, y_T^\alpha)\|_\mathcal{Y} \leq K_2^\alpha. \tag{2.19}
\]

**Proof:** Suppose that \((u, u_T) \in \mathcal{U}\) and \(\alpha \in (0, 1]\) are arbitrarily chosen, and let \((y^\alpha, y_T^\alpha) = \mathcal{S}_\alpha(u, u_T)\). The result will be established in a series of a priori estimates. To this end, we will in the following denote by \(C_i, i \in \mathbb{N}\), positive constants which may depend on the quantities mentioned in the statement, but not on \(\alpha \in (0, 1]\).

**First a priori estimate:**

We add \(y^\alpha\) on both sides of \((2.4)\) and \(y_T^\alpha\) on both sides of \((2.5)\). Then we test the equation resulting from \((2.4)\) by \(\partial_t y^\alpha\) to find the estimate

\[
\int_0^t \int_{\Omega} |\partial_t y^\alpha|^2 \, dx \, dt + \int_0^t \int_{\Gamma} |\partial_t y_T^\alpha|^2 \, dx \, d\Gamma + \frac{1}{2} \|y^\alpha(t)\|_V^2 + \frac{1}{2} \|y_T^\alpha(t)\|_V^2 \tag{2.20}
\]

\[
+ \varphi(\alpha) \int_{\Omega} h(y^\alpha(t)) \, dx + \int_{\Omega} f_2(y^\alpha(t)) \, dx + \psi(\alpha) \int_{\Gamma} h(y_T^\alpha(t)) \, d\Gamma + \int_{\Gamma} g_2(y_T^\alpha(t)) \, d\Gamma \leq \Phi_\alpha + \frac{1}{2} \|y^\alpha\|_V^2 + \frac{1}{2} \|y_T^\alpha\|_V^2 + \int_0^t \int_{\Omega} |u| |\partial_t y^\alpha| \, dx \, dt + \int_0^t \int_{\Gamma} |u_T| |\partial_t y_T^\alpha| \, d\Gamma \, dt \tag{2.20}
\]

where, owing to \((A2), (1.11), (2.7), \) and \((2.12), \) the expression

\[
\Phi_\alpha := \varphi(\alpha) \int_{\Omega} h(y^\alpha_0) \, dx + \int_{\Omega} f_2(y^\alpha_0) \, dx + \psi(\alpha) \int_{\Gamma} h(y_T^\alpha_0) \, d\Gamma + \int_{\Gamma} g_2(y_T^\alpha_0) \, d\Gamma
\]
is bounded from above. By virtue of (2.13), the same is true for the expression

\[ \frac{1}{2} \| y_0 \|_V^2 + \frac{1}{2} \| y_0^\alpha \|_{V^1}^2. \]

Moreover, by (A2), Lemma 2.3(i), and since \( h \) is bounded from below on \([-1, 1]\), also the expression in the second line of (2.20) is bounded from below. Hence, after applying Young’s inequality to the expressions in the fourth line, we can conclude from Gronwall’s lemma that

\[ \| y^\alpha \|_{H^1(0,T;H) \cap C^0([0,T];V)} + \| y_0^\alpha \|_{H^1(0,T;H) \cap C^0([0,T];V^1)} \leq C_1. \]

Second a priori estimate:

We multiply (2.4) by \(-\Delta y^\alpha\) and integrate over \( \Omega \) and by parts, using the boundary condition (2.5). We obtain:

\[
\begin{align*}
\| \Delta y^\alpha(t) \|_H^2 &+ \int_\Omega \varphi(\alpha) h''(y^\alpha(t)) |\nabla y^\alpha(t)|^2 \, dx + \frac{d}{dt} \int_\Gamma \varphi(\alpha) h(y^\alpha(t)) \, d\Gamma \\
&+ \int_\Gamma \varphi(\alpha) h''(y^\alpha(t)) |\nabla y^\alpha(t)|^2 \, d\Gamma + \int_\Gamma \varphi(\alpha) \psi(\alpha) |h'(y^\alpha(t))|^2 \, d\Gamma \\
&= \int_\Gamma \varphi(\alpha) h'(y^\alpha(t)) u_\Gamma(t) \, d\Gamma - \int_\Gamma \varphi(\alpha) h'(y^\alpha(t)) g_2(y^\alpha(t)) \, d\Gamma \\
&+ \int_{\Omega} (\partial_t y^\alpha + f_2'(y^\alpha(t))) \Delta y^\alpha(t) \, dx - \int_{\Omega} u(t) \Delta y^\alpha(t) \, dx. \quad (2.22)
\end{align*}
\]

Now notice that \( h'' > 0 \) in \((-1, 1)\), which implies that the two integrals, in which \( h'' \) occurs in the integrands, are both nonnegative. Moreover, (2.9) implies that

\[
\int_\Gamma \varphi(\alpha) \psi(\alpha) |h'(y^\alpha(t))|^2 \, d\Gamma \geq \frac{1}{C_{\varphi\psi}} \int_\Gamma (\varphi(\alpha))^2 |h'(y^\alpha(t))|^2 \, d\Gamma.
\]

Therefore, in view of (A2), (2.7), and Lemma 2.3(i), the boundary integral

\[
\int_\Gamma \varphi(\alpha) h'(y^\alpha(t)) g_2(y^\alpha(t)) \, d\Gamma
\]

can be handled using Young’s inequality. Hence, integrating (2.22) over \((0,T)\), and invoking the general assumptions on \( \varphi, \psi, f_2, g_2, u, u_\Gamma \) as well as the estimate (2.21) for \( \partial_t y^\alpha \), we can infer from Young’s inequality that

\[ \| \Delta y^\alpha \|_{L^2(Q)} \leq C_2. \]

Now, it is clear that \( \| f_2'(y^\alpha) \|_{L^\infty(Q)} \leq C_3 \), and thus comparison in (2.4) yields that also

\[ \| \varphi(\alpha) h'(y^\alpha) \|_{L^2(Q)} \leq C_4. \]

Next, we invoke [2, Theorem 3.2, p. 1.79] with the specifications

\[ A = -\Delta, \quad g_0 = y_{|\Gamma}, \quad p = 2, \quad r = 0, \quad s = 3/2, \]
to conclude that
\[ \int_0^T \| y^\alpha(t) \|_{H^{3/2}(\Omega)}^2 \, dt \leq C_5 \int_0^T \left( \| \Delta y^\alpha(t) \|_H^2 + \| y^\alpha(t) \|_{V_1}^2 \right) \, dt, \]  
whence it follows that
\[ \| y^\alpha \|_{L^2(0,T;H^{3/2}(\Omega))} \leq C_6. \]  
Hence, by the trace theorem [2, Theorem 2.27, p. 1.64], we have that
\[ \| \partial_n y^\alpha \|_{L^2(0,T;H^1(\Gamma))} \leq C_7. \]  

**Third a priori estimate:**

We now test the differential equation in (2.5) by \( \psi(\alpha) h'(y_G^\alpha) \). Integrating by parts, we obtain
\[ (\psi(\alpha))^2 \int_0^T \int_{\Gamma} |h'(y_G^\alpha)|^2 \, d\Gamma \, dt + \psi(\alpha) \int_0^T \int_{\Gamma} h''(y_G^\alpha) \, |\nabla y_G^\alpha|^2 \, d\Gamma \, dt \]
\[ = \int_0^T \int_{\Gamma} \psi(\alpha) h'(y_G^\alpha) z^\alpha_G \, d\Gamma \, dt, \]
where \( z^\alpha_G := u_\Gamma - \partial_t y_G^\alpha - \partial_n y^\alpha - g_\alpha(y_G^\alpha) \). Owing to the previous estimates (cf., in particular, (2.21) and (2.27)), the functions \( z^\alpha_G \) are bounded in \( L^2(\Sigma) \) by a constant which does not depend on \( \alpha \in (0,1] \). Hence, using Young’s inequality and the positivity of \( h'' \) on \((-1,1)\), we can conclude that
\[ \| \psi(\alpha) h'(y_G^\alpha) \|_{L^2(\Sigma)} \leq C_8, \]
whence, by comparison in (2.5), also
\[ \| \Delta y_G^\alpha \|_{L^2(\Sigma)} \leq C_9. \]
Therefore, we can deduce that
\[ \| y_G^\alpha \|_{L^2(0,T;H^2(\Gamma))} \leq C_{10}. \]
Moreover, by virtue of (2.21), (2.23), (2.31), and since \( \Omega \) has a smooth boundary, we can infer from standard elliptic estimates that
\[ \| y^\alpha \|_{L^2(0,T;H^2(\Omega))} \leq C_{11}. \]
Collecting the above estimates, we have thus shown that
\[ \|(y^\alpha, y_G^\alpha)\|_Y \leq C_{12}, \]
and the assertion of the lemma is finally proved. \( \blacksquare \)

**Remark 2.6:** We cannot expect a uniform in \( \alpha \) bound to hold for \( \|(y^\alpha, y_G^\alpha)\|_X \). In fact, in the \( L^\infty \) bounds derived in (2.16) we may have \( r_+(\alpha) \to -1 \) and/or \( r^*(\alpha) \to +1 \) as \( \alpha \searrow 0 \).
3 Existence and approximation of optimal controls

Our first aim in this section is to prove the following existence result:

**Theorem 3.1:** Suppose that the assumptions (A1)–(A4) are satisfied. Then the optimal control problem \((P_0)\) admits a solution.

Before proving Theorem 3.1, we introduce a family of auxiliary optimal control problems \((P_\alpha)\), which is parametrized by \(\alpha \in (0, 1]\). In what follows, we will always assume that \(h\) is given by (1.11) and that \(\varphi\) and \(\psi\) are functions that are continuous on \((0, 1]\) and satisfy the conditions (2.7)–(2.9). For \(\alpha \in (0, 1]\), let us denote by \(S_\alpha\) the operator mapping the control pair \((u, u_T)\) into the unique solution \((y^\alpha, y_T^\alpha)\) to the problem (2.4)–(2.6), with \((y_0^\alpha, y_T^\alpha)\) satisfying (2.11)–(2.13). We define:

\[
(P_\alpha) \quad \text{Minimize} \quad J((y, y_T), (u, u_T)) \quad \text{over} \quad Y \times U_{ad} \quad \text{subject to the condition that (2.4)–(2.6) be satisfied.} \quad (3.1)
\]

The following result is a consequence of [5] Theorem 3.1.

**Lemma 3.2:** Suppose that the assumptions (A1)–(A4) and (2.7)–(2.13) are fulfilled. Let \(\alpha \in (0, 1]\) be given. Then the optimal control problem \((P_\alpha)\) admits a solution.

**Proof of Theorem 3.1:** Let \(\{\alpha_n\} \subset (0, 1]\) be any sequence such that \(\alpha_n \searrow 0\) as \(n \to \infty\). By virtue of Lemma 3.2, for any \(n \in \mathbb{N}\) we may pick an optimal pair

\[
((y^{\alpha_n}, y_T^{\alpha_n}), (u^{\alpha_n}, u_T^{\alpha_n})) \in Y \times U_{ad}
\]

for the optimal control problem \((P_{\alpha_n})\). Obviously, we have

\[
(y^{\alpha_n}, y_T^{\alpha_n}) = S_{\alpha_n}(u^{\alpha_n}, u_T^{\alpha_n}) \quad \forall n \in \mathbb{N},
\]

and it follows from Lemma 2.3(i) that

\[
|y^{\alpha_n}| < 1 \quad \text{a.e. in } Q, \quad |y_T^{\alpha_n}| < 1 \quad \text{a.e. on } \Sigma. \quad (3.2)
\]

Moreover, Lemma 2.5 implies that \(\|(y^{\alpha_n}, y_T^{\alpha_n})\|_Y \leq K^*_2\) for all \(n \in \mathbb{N}\). Thus, without loss of generality we may assume that there are \((\bar{u}, \bar{u}_T) \in U_{ad}\) and \((\bar{y}, \bar{y}_T) \in Y\) such that

\[
(u^{\alpha_n}, u_T^{\alpha_n}) \to (\bar{u}, \bar{u}_T) \quad \text{weakly-star in } \mathcal{X}, \quad (3.3)
\]

\[
y^{\alpha_n} \to \bar{y} \quad \text{weakly-star in } H^1(0, T; H) \cap L^\infty(0, T; V) \cap L^2(0, T; H^2(\Omega)), \quad (3.4)
\]

\[
y_T^{\alpha_n} \to \bar{y}_T \quad \text{weakly-star in } H^1(0, T; H_T) \cap L^\infty(0, T; V_T) \cap L^2(0, T; H^2(T)). \quad (3.5)
\]

We remark here that, due to the continuity of the embedding

\[
H^1(0, T; H) \cap L^2(0, T; H^2(\Omega)) \subset C^0([0, T]; V),
\]

we have in fact \(\bar{y} \in C^0([0, T]; V)\), and, by the same token, \(\bar{y}_T \in C^0([0, T]; V_T)\). By the Aubin-Lions lemma (see [10] Sect. 8, Cor. 4), we also have

\[
y^{\alpha_n} \to \bar{y} \quad \text{strongly in } C^0([0, T]; H) \cap L^2(0, T; V), \quad (3.6)
\]

\[
y_T^{\alpha_n} \to \bar{y}_T \quad \text{strongly in } C^0([0, T]; H_T) \cap L^2(0, T; V_T). \quad (3.7)
\]
In particular, owing to (2.6) and (2.13) it holds $\bar{y}(\cdot, 0) = y_0$, as well as $\bar{y}_\Gamma(\cdot, 0) = y_0\Gamma$. In addition, the Lipschitz continuity of $f'_2$ and $g'_2$ on $[-1, 1]$ yields that
\begin{align*}
f'_2(y^{\alpha_n}) &\to f'_2(\bar{y}) \quad \text{strongly in } C^0([0, T]; H), \\
g'_2(y^{\alpha_n}_\Gamma) &\to g'_2(\bar{y}_\Gamma) \quad \text{strongly in } C^0([0, T]; H_\Gamma).
\end{align*}
Moreover, (2.24) and (2.29) show that without loss of generality we may assume that
\begin{align*}
\varphi(\alpha_n) h'(y^{\alpha_n}) &\to \xi \quad \text{weakly in } L^2(0, T; H), \\
\psi(\alpha_n) h'(y^{\alpha_n}_\Gamma) &\to \xi_\Gamma \quad \text{weakly in } L^2(0, T; H_\Gamma),
\end{align*}
for some weak limits $\xi$ and $\xi_\Gamma$. Next, we show that $\xi_\Gamma \in \partial I_{[-1, 1]}(\bar{y})$ a.e. in $Q$ and $\xi \in \partial I(\bar{y})$ a.e. in $\Sigma$. Once this will be shown, we can pass to the limit as $n \to \infty$ in the approximating systems (2.7)–(2.13) to arrive at the conclusion that $(\bar{y}, \bar{y}_\Gamma) = S_0(\bar{u}, \bar{u}_\Gamma)$, i.e., the pair $((\bar{y}, \bar{y}_\Gamma), (\bar{u}, \bar{u}_\Gamma))$ is admissible for $(P_0)$.

Now, recalling (1.11) and owing to the convexity of $h$, we have, for every $n \in \mathbb{N}$,
\begin{align*}
\int_0^T \int_{\Omega} \varphi(\alpha_n) h(y^{\alpha_n}) \, dx \, dt + \int_0^T \int_{\Omega} \psi(\alpha_n) h(y^{\alpha_n}_\Gamma) (z - y^{\alpha_n}) \, dx \, dt &\leq \int_0^T \int_{\Omega} \varphi(\alpha_n) h(z) \, dx \, dt
\end{align*}
for all $z \in K = \{ v \in L^2(Q) : |v| \leq 1 \text{a.e. in } Q \}$.

Thanks to (2.8), the integral on the right-hand side of (3.12) tends to zero as $n \to \infty$. The same holds for the first integral on the left-hand side. Hence, invoking (3.6) and (3.10), the passage to the limit as $n \to \infty$ leads to the inequality
\begin{align*}
\int_0^T \int_{\Omega} \xi(\bar{y} - z) \, dx \, dt &\geq 0 \quad \forall z \in K.
\end{align*}

Inequality (3.13) entails that $\xi$ is an element of the subdifferential of the extension $I$ of $I_{[-1, 1]}$ to $L^2(Q)$, which means that $\xi \in \partial I(\bar{y})$ or equivalently (cf. [2, Ex. 2.3.3., p. 25]) $\xi \in \partial I_{[-1, 1]}(\bar{y})$ a.e. in $Q$. Similarly we prove that $\xi_\Gamma \in \partial I_{[-1, 1]}(\bar{y})$ a.e. in $\Sigma$.

It remains to show that $((\bar{y}, \bar{y}_\Gamma), (\bar{u}, \bar{u}_\Gamma))$ is in fact an optimal pair of $(P_0)$. To this end, let $(v, v_\Gamma) \in \mathcal{U}_{ad}$ be arbitrary. In view of the convergence properties (3.3)–(3.7), and using the weak sequential lower semicontinuity of the cost functional, we have
\begin{align*}
J((\bar{y}, \bar{y}_\Gamma), (\bar{u}, \bar{u}_\Gamma)) &= J(S_0(\bar{u}, \bar{u}_\Gamma), (\bar{u}, \bar{u}_\Gamma)) \\
&\leq \liminf_{n \to \infty} J(S_{\alpha_n}(u^{\alpha_n}, u^{\alpha_n}_\Gamma), (u^{\alpha_n}, u^{\alpha_n}_\Gamma)) \\
&\leq \liminf_{n \to \infty} J(S_{\alpha_n}(v, v_\Gamma), (v, v_\Gamma)) = J(S_0(v, v_\Gamma), (v, v_\Gamma)),
\end{align*}
where for the last equality the continuity of the cost functional with respect to the first variable was used. With this, the assertion is completely proved.

\textbf{Corollary 3.3:} Let the general assumptions (A1)–(A4) and (2.7)–(2.13) be fulfilled, and let the sequences $\{\alpha_n\} \subset (0, 1]$ and $\{(u^{\alpha_n}, u^{\alpha_n}_\Gamma)\} \subset \mathcal{U}$ be given such that, as $n \to \infty$, $\alpha_n \searrow 0$ and $(u^{\alpha_n}, u^{\alpha_n}_\Gamma) \rightharpoonup (\bar{u}, \bar{u}_\Gamma)$ weakly-star in $\mathcal{X}$. Then it holds
\begin{align*}
S_{\alpha_n}(u^{\alpha_n}, u^{\alpha_n}_\Gamma) &\rightharpoonup S_0(\bar{u}, \bar{u}_\Gamma) \quad \text{weakly-star in } \left( H^1(0, T; H) \cap L^\infty(0, T; V) \\
\cap L^2(0, T; H^2(\Omega)) \right) \times \left( H^1(0, T; H_\Gamma) \cap L^\infty(0, T; V_\Gamma) \cap L^2(0, T; H^2(\Gamma)) \right).
\end{align*}
Moreover, we have that
\[
\lim_{n \to \infty} J(S_{\alpha_n}(v, v_{T}), (v, v_{T})) = J(S_0(v, v_{T}), (v, v_{T})) \quad \forall (v, v_{T}) \in \mathcal{U}.
\] (3.16)

**Proof:** By the same arguments as in the first part of the proof of Theorem 3.1, we can conclude that (3.15) holds at least for some subsequence. But since the limit, being the unique solution to the state system (1.3)–(1.6), is the same for all convergent subsequences, (3.15) is true for the whole sequence. Now, let \((v, v_{T}) \in \mathcal{U}\) be arbitrary. Then (see (3.6)–(3.7)) \(S_{\alpha_n}(v, v_{T})\) converges strongly to \(S_0(v, v_{T})\) in \((C^0([0, T]; H) \cap L^2(0, T; V)) \times (C^0([0, T]; H_T) \cap L^2(0, T; V_T))\), and (3.16) follows from the continuity properties of the cost functional with respect to its first argument.

Theorem 3.1 does not yield any information on whether every solution to the optimal control problem \((\mathcal{P}_0)\) can be approximated by a sequence of solutions to the problems \((\mathcal{P}_\alpha)\). As already announced in the Introduction, we are not able to prove such a general “global” result. Instead, we can only give a “local” answer for every individual optimizer of \((\mathcal{P}_0)\). For this purpose, we employ a trick due to Barbu [1]. To this end, let \(((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T)) \in \mathcal{Y} \times \mathcal{U}_{ad}\), where \((\bar{y}, \bar{y}_T) = S_0(\bar{u}, \bar{u}_T)\), be an arbitrary but fixed solution to \((\mathcal{P}_0)\). We associate with this solution the “adapted cost functional”
\[
\tilde{J}((y, y_{T}), (u, u_{T})) := J((y, y_{T}), (u, u_{T})) + \frac{1}{2} \| u - \bar{u} \|^2_{L^2(Q)} + \frac{1}{2} \| u_{T} - \bar{u}_{T} \|^2_{L^2(\Sigma)} \tag{3.17}
\]
and a corresponding “adapted optimal control problem”
\[
(\tilde{\mathcal{P}}_\alpha) \quad \text{Minimize} \quad \tilde{J}((y, y_{T}), (u, u_{T})) \quad \text{over} \quad \mathcal{Y} \times \mathcal{U}_{ad} \quad \text{subject to the condition that} \quad (2.4)–(2.6) \text{ be satisfied.} \tag{3.18}
\]

With a proof that resembles that of [5] Theorem 3.1] and needs no repetition here, we can show the following result.

**Lemma 3.4:** Suppose that the assumptions \((A1)–(A4)\) and \((2.7)–(2.13)\) are satisfied, and let \(\alpha \in (0, 1]\). Then the optimal control problem \((\tilde{\mathcal{P}}_\alpha)\) admits a solution.

We are now in the position to give a partial answer to the question raised above. We have the following result.

**Theorem 3.5:** Let the general assumptions \((A1)–(A4)\) and \((2.7)–(2.13)\) be fulfilled, and suppose that \(((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T)) \in \mathcal{Y} \times \mathcal{U}_{ad}\) is any fixed solution to the optimal control problem \((\mathcal{P}_0)\). Then, for every sequence \(\{\alpha_n\} \subset (0, 1]\) such that \(\alpha_n \searrow 0\) as \(n \to \infty\), and for any \(n \in \mathbb{N}\) there exists a pair \(((\bar{y}^{\alpha_n}, \bar{y}_T^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n})) \in \mathcal{Y} \times \mathcal{U}_{ad}\) solving the
adapted problem \((\tilde{P}_{\alpha_n})\) and such that, as \(n \to \infty\),

\[
\begin{align*}
(\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n}) & \to (\bar{u}, \bar{u}_T) \quad \text{strongly in } \mathcal{H}, \\
\bar{y}^{\alpha_n} & \to \bar{y} \quad \text{weakly-star in } H^1(0, T; H) \cap L^\infty(0, T; V) \cap L^2(0, T; H^2(\Omega)), \\
\bar{y}_T^{\alpha_n} & \to \bar{y}_T \quad \text{weakly-star in } H^1(0, T; H_T) \cap L^\infty(0, T; V_T) \cap L^2(0, T; H^2(\Gamma)), \\
\bar{J}((\bar{y}^{\alpha_n}, \bar{y}_T^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n})) & \to \bar{J}((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T)).
\end{align*}
\]

**Proof:** For every \(\alpha \in (0, 1]\), we pick an optimal pair \(((\bar{y}^\alpha, \bar{y}_T^\alpha), (\bar{u}^\alpha, \bar{u}_T^\alpha)) \in \mathcal{Y} \times \mathcal{U}_{ad}\) for the adapted problem \((\tilde{P}_\alpha)\). By the boundedness of \(\mathcal{U}_{ad}\), there are some sequence \(\{\alpha_n\} \subset (0, 1]\), with \(\alpha_n \searrow 0\) as \(n \to \infty\), and some pair \((u, u_T) \in \mathcal{U}_{ad}\) satisfying

\[
(\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n}) \to (u, u_T) \quad \text{weakly in } \mathcal{X} \quad \text{as } n \to \infty.
\]

Moreover, owing to Lemma 2.5, we may without loss of generality assume that there is some limit element \((y, y_T) \in \mathcal{Y}\) such that \((3.20)\) and \((3.21)\) are satisfied with \(\bar{y}\) and \(\bar{y}_T\) replaced by \(y\) and \(y_T\), respectively. From Corollary 3.3 (see \((3.15)\)) we can infer that actually

\[
(y, y_T) = \mathcal{S}_0(u, u_T),
\]

which implies, in particular, that \(((y, y_T), (u, u_T))\) is an admissible pair for \((P_0)\).

We now aim to prove that \((u, u_T) = (\bar{u}, \bar{u}_T)\). Once this will be shown, we can infer from the unique solvability of the state system \((1.3)-(1.6)\) and that \((y, y_T) = (\bar{y}, \bar{y}_T)\), whence \((3.20)\) and \((3.21)\) will follow. We will check \((3.19)\) and \((3.22)\) as well. Moreover, the convergences in \((3.19)-(3.22)\) will hold for the whole family \(((y^\alpha, y^\alpha_T, (\bar{u}^\alpha, \bar{u}_T^\alpha))\) as \(\alpha \searrow 0\).

Indeed, we have, owing to the weak sequential lower semicontinuity of \(\bar{J}\), and in view of the optimality property of \(((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T))\) for problem \((P_0)\),

\[
\liminf_{n \to \infty} \bar{J}((\bar{y}^{\alpha_n}, \bar{y}_T^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n})) \\
\geq J((y, y_T), (u, u_T)) + \frac{1}{2} \|u - \bar{u}\|_{L^2(Q)} + \frac{1}{2} \|u_T - \bar{u}_T\|_{L^2(\Sigma)}
\]

\[
\geq J((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T)) + \frac{1}{2} \|u - \bar{u}\|_{L^2(Q)} + \frac{1}{2} \|u_T - \bar{u}_T\|_{L^2(\Sigma)}.
\]

On the other hand, the optimality property of \(((\bar{y}^{\alpha_n}, \bar{y}_T^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n}))\) for problem \((\tilde{P}_{\alpha_n})\) yields that for any \(n \in \mathbb{N}\) we have

\[
\bar{J}((\bar{y}^{\alpha_n}, \bar{y}_T^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n})) = \bar{J}(\mathcal{S}_{\alpha_n}(\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n})) \\
\leq \bar{J}(\mathcal{S}_{\alpha_n}(\bar{u}, \bar{u}_T), (\bar{u}, \bar{u}_T)),
\]

whence, taking the limes superior as \(n \to \infty\) on both sides and invoking \((3.16)\) in Corollary 3.3,

\[
\limsup_{n \to \infty} \bar{J}((\bar{y}^{\alpha_n}, \bar{y}_T^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_T^{\alpha_n})) \leq \bar{J}(\mathcal{S}_0(\bar{u}, \bar{u}_T), (\bar{u}, \bar{u}_T)) = \bar{J}((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T))
\]

\[
= J((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T)).
\]
Combining (3.25) with (3.27), we have thus shown that
\[ \frac{1}{2} \| u - \bar{u} \|_{L^2(Q)}^2 + \frac{1}{2} \| u_\Gamma - \bar{u}_\Gamma \|_{L^2(\Sigma)}^2 = 0, \]
so that \((u, u_\Gamma) = (\bar{u}, \bar{u}_\Gamma)\) and thus also \((y, y_\Gamma) = (\bar{y}, \bar{y}_\Gamma)\). Moreover, (3.25) and (3.27) also imply that
\[ J((\bar{y}, \bar{y}_\Gamma), (\bar{u}, \bar{u}_\Gamma)) = \liminf_{n \to \infty} J((\bar{y}^{\alpha_n}, \bar{y}_\Gamma^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_\Gamma^{\alpha_n})) = \limsup_{n \to \infty} J((\bar{y}^{\alpha_n}, \bar{y}_\Gamma^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_\Gamma^{\alpha_n})) = \lim_{n \to \infty} J((\bar{y}^{\alpha_n}, \bar{y}_\Gamma^{\alpha_n}), (\bar{u}^{\alpha_n}, \bar{u}_\Gamma^{\alpha_n})), \]
which proves (3.22) and, at the same time, also (3.19). The assertion is thus completely proved.

4 The optimality system

In this section our aim is to establish first-order necessary optimality conditions for the optimal control problem \((P_0)\). This will be achieved by deriving first-order necessary optimality conditions for the adapted optimal control problems \((\bar{P}_\alpha)\) and passing to the limit as \(\alpha \downarrow 0\). We will finally show that in the limit certain generalized first-order necessary conditions of optimality result. To fix things once and for all, we will throughout the entire section assume that \(h\) is given by (1.11) and that (2.7)–(2.9) are satisfied.

4.1 The linearized system

For the derivation of first-order optimality conditions, it is essential to show the Fréchet-differentiability of the control-to-state operator. In view of the occurrence of the indicator function in (1.5), this is impossible for the control-to-state operator \(S_0\) of the state system (1.3)–(1.6). It is, however (cf. [5]), possible for the control-to-state operators \(S_\alpha\) of the approximating systems (2.4)–(2.6). In preparation of a corresponding theorem, we now consider for given \((k, k_\Gamma) \in X\) the following linearized version of (2.4)–(2.6):

\[ \partial_t \bar{y}^\alpha - \Delta \bar{y}^\alpha + \varphi(\alpha) h''(\bar{y}^\alpha) \bar{y}^\alpha + f''_2(\bar{y}^\alpha) \bar{y}^\alpha = k \quad \text{a. e. in } Q, \tag{4.1} \]
\[ \bar{y}^\alpha_{|_{\partial Q}} = \bar{y}_\Gamma^\alpha, \quad \partial_n \bar{y}^\alpha + \partial_t \bar{y}_\Gamma^\alpha - \Delta \bar{y}_\Gamma^\alpha + \psi(\alpha) h''(\bar{y}_\Gamma^\alpha) \bar{y}_\Gamma^\alpha + g''(\bar{y}_\Gamma^\alpha) \bar{y}_\Gamma^\alpha = k_\Gamma \quad \text{a. e. on } \Sigma, \tag{4.2} \]
\[ \bar{y}^\alpha(\cdot, 0) = 0 \quad \text{a. e. in } \Omega, \quad \bar{y}_\Gamma^\alpha(\cdot, 0) = 0 \quad \text{a. e. on } \Gamma, \tag{4.3} \]
with given functions \((\bar{y}^\alpha, \bar{y}_\Gamma^\alpha) \in Y\). In the next sections, \((\bar{y}^\alpha, \bar{y}_\Gamma^\alpha)\) will be the unique solution to the system (2.4)–(2.6) corresponding to a reference control. By [5, Theorem 2.2], the system (1.1)–(1.3) admits for every \((k, k_\Gamma) \in C\) (and thus, a fortiori, for every \((k, k_\Gamma) \in X\)) a unique solution \((\bar{y}^\alpha, \bar{y}_\Gamma^\alpha) \in Y\), and the linear mapping \((k, k_\Gamma) \mapsto (\bar{y}^\alpha, \bar{y}_\Gamma^\alpha)\) is continuous from \(C\) into \(Y\) and thus also from \(X\) into \(Y\).
4.2 Differentiability of the control-to-state operator $S_\alpha$

We have the following differentiability result, which is a direct consequence of [3, Theorem 3.2].

**Theorem 4.1:** Let the assumptions (A2)–(A4) and (2.7)–(2.13) be satisfied, and let $\alpha \in (0,1]$ be given. Then we have the following results:

(i) Let $(u,u_\Gamma) \in \mathcal{U}$ be arbitrary. Then the control-to-state mapping $S_\alpha$, viewed as a mapping from $X$ into $Y$, is Fréchet differentiable at $(u,u_\Gamma)$, and the Fréchet derivative $D_S\alpha(u,u_\Gamma)$ is given by $D_S\alpha(u,u_\Gamma)(k,k_\Gamma) = (\dot{y}^\alpha,\ddot{y}^\alpha)$, where for any given $(k,k_\Gamma) \in X$ the pair $(\dot{y}^\alpha,\ddot{y}^\alpha)$ denotes the solution to the linearized system (4.1)–(4.3).

(ii) The mapping $D_S\alpha : \mathcal{U} \to \mathcal{L}(X,Y)$, $(u,u_\Gamma) \mapsto D_S\alpha(u,u_\Gamma)$ is Lipschitz continuous on $\mathcal{U}$ in the following sense: there is a constant $K_3^\alpha(\alpha) > 0$ such that for all $(u_1,u_{1\Gamma}),(u_2,u_{2\Gamma}) \in \mathcal{U}$ and all $(k,k_\Gamma) \in X$ it holds

$$
\|(D_S\alpha(u_1,u_{1\Gamma}) - D_S\alpha(u_2,u_{2\Gamma}))(k,k_\Gamma)\|_Y \\
\leq K_3^\alpha(\alpha) \|(u_1,u_{1\Gamma}) - (u_2,u_{2\Gamma})\|_\mathcal{U} \|(k,k_\Gamma)\|_\mathcal{H}.
$$

**Remark 4.2:** From Theorem 4.1 it easily follows, using the quadratic form of $\tilde{J}$ and the chain rule, that for any $\alpha \in (0,1]$ the reduced cost functional

$$
\tilde{J}_\alpha(u,u_\Gamma) := \tilde{J}(S_\alpha(u,u_\Gamma),(u,u_\Gamma))
$$

is Fréchet differentiable, where, with obvious notation, the Fréchet derivative has the form

$$
D\tilde{J}_\alpha(u,u_\Gamma) = D_{(\tilde{y},\tilde{y}_\Gamma)}\tilde{J}(S_\alpha(u,u_\Gamma),(u,u_\Gamma)) \circ D_S\alpha(u,u_\Gamma) + D_{(u,u_\Gamma)}\tilde{J}(S_\alpha(u,u_\Gamma),(u,u_\Gamma)).
$$

4.3 First-order necessary optimality conditions for $(\tilde{P}_\alpha)$

Suppose now that $(\bar{u},\bar{u}_\Gamma) \in \mathcal{U}_{\text{ad}}$ is any local minimizer for $(\mathcal{P}_0)$ with associated state $(\bar{y},\bar{y}_\Gamma) = S_0(\bar{u},\bar{u}_\Gamma) \in \mathcal{Y}$. With [1,6] at hand it is now easy to formulate the variational inequality that every local minimizer $(\bar{u}^\alpha,\bar{u}_2^\alpha)$ of $(\tilde{P}_\alpha)$ has to satisfy. Indeed, by the convexity of $\mathcal{U}_{\text{ad}}$, we must have

$$
D\tilde{J}_\alpha(\bar{u}^\alpha,\bar{u}_2^\alpha)(v - \bar{u}^\alpha,v_\Gamma - \bar{u}_2^\alpha) \geq 0 \quad \forall (v,v_\Gamma) \in \mathcal{U}_{\text{ad}}.
$$

Identification of the expressions in (4.7) from (1.2) and Theorem 4.1 yields the following result (see also [5, Corollary 3.3]).

**Corollary 4.3:** Let the assumptions (A1)–(A4) and (2.7)–(2.13) be satisfied. For a given $\alpha \in (0,1]$, if $(\bar{u}^\alpha,\bar{u}_2^\alpha) \in \mathcal{U}_{\text{ad}}$ is an optimal control for the control problem $(\tilde{P}_\alpha)$
with associated state \((\bar{y}^a, \bar{y}^\alpha)^T) = S_\alpha(\bar{u}^a, \bar{u}^\alpha) \in \mathcal{Y}\) then we have for every \((v, v_T) \in \mathcal{U}_{ad}\)
\[
\beta_1 \int_0^T \int_\Omega (\bar{y}^a - z_Q) \dot{y}^a \, dx \, dt + \beta_2 \int_0^T \int_\Gamma (\bar{y}^\alpha - z_S) \dot{y}^\alpha \, d\Gamma \, dt
\]
\[
+ \beta_3 \int_0^T (\bar{y}^a(\cdot, T) - z_T) \dot{y}^a(\cdot, T) \, dx + \beta_3 \int_\Gamma (\bar{y}^\alpha(\cdot, T) - z_{\Gamma, T}) \dot{y}^\alpha(\cdot, T) \, d\Gamma
\]
\[
+ \int_0^T \int_\Omega (\beta_4 \bar{u}^a + (\bar{u}^a - \bar{u})) (v - \bar{u}^a) \, dx \, dt
\]
\[
+ \int_0^T \int_\Gamma (\beta_5 \bar{u}^\alpha + (\bar{u}^\alpha - \bar{u}_T)) (v_T - \bar{u}_T^\alpha) \, d\Gamma \, dt \geq 0,
\]
where \((\bar{y}^a, \bar{y}^\alpha)^T) \in \mathcal{Y}\) is the unique solution to the linearized system \((A1) - (A3)\) associated with \((k^a, k^\alpha)^T) = (v - \bar{u}^a, v_T - \bar{u}_T^\alpha)\).

We are now in the position to derive the first-order necessary optimality conditions for the control problem for \((\bar{P}_\alpha)\). For technical reasons, we need to make a compatibility assumption:

\[(A5) \quad \text{It holds } z_{\Gamma, T} = z_T|_{\Gamma}.\]

The following result is a direct consequence of \([5] \text{ Theorem 3.4}].\)

**Theorem 4.4:** Let the assumptions \((A1) - (A5)\) and \((A7) - (A13)\) be satisfied. Moreover, assume that \(\alpha \in (0, 1]\) is given and \((\bar{u}^a, \bar{u}^\alpha) \in \mathcal{U}_{ad}\) is an optimal control for the control problem \((\bar{P}_\alpha)\) with associated state \((\bar{y}^a, \bar{y}^\alpha)^T) = S_\alpha(\bar{u}^a, \bar{u}^\alpha) \in \mathcal{Y}\). Then the adjoint state system
\[
- \partial_t p^a - \Delta p^a + \varphi(\alpha) h''(\bar{y}^a) p^a + g''_2(\bar{y}^a) p^a = \beta_1 (\bar{y}^a - z_Q) \quad \text{a.e. in } Q,
\]
\[
p^a|_\Gamma = p^a_\Gamma, \quad \partial_t p^a - \partial_t p^\alpha - \Delta p^\alpha + \psi(\alpha) h''(\bar{y}^\alpha) p^\alpha + g''_2(\bar{y}^\alpha) p^\alpha = \beta_2 (\bar{y}^\alpha - z_S)
\]
\[
a.e. \text{ on } \Sigma,
\]
\[
p^a(\cdot, T) = \beta_3 (\bar{y}^a(\cdot, T) - z_T) \quad \text{a.e. in } Q,
\]
\[
p^\alpha(\cdot, T) = \beta_3 (\bar{y}^\alpha(\cdot, T) - z_{\Gamma, T}) \quad \text{a.e. on } \Gamma,
\]
has a unique solution \((\bar{p}^a, \bar{p}^\alpha)^T) \in \mathcal{Y}\), and for every \((v, v_T) \in \mathcal{U}_{ad}\) we have
\[
\int_0^T \int_\Omega (\bar{p}^a + \beta_4 \bar{u}^a + (\bar{u}^a - \bar{u})) (v - \bar{u}^a) \, dx \, dt
\]
\[
+ \int_0^T \int_\Gamma (\beta_5 \bar{u}^\alpha + (\bar{u}^\alpha - \bar{u}_T)) (v_T - \bar{u}_T^\alpha) \, d\Gamma \, dt \geq 0.
\]
Remark 4.5: The compatibility condition \((A5)\) is needed to guarantee the compatibility property \(p^\alpha(T)|_t = P^\alpha_1(T)\), which (cf. [5]) is necessary to obtain the regularity \((\bar{p}^\alpha, \bar{p}^\alpha_1) \in Y\).

4.4 The optimality conditions for \((P_0)\)

Suppose now that \((\bar{u}, \bar{u}_f) \in U_{ad}\) is a local minimizer for \((P_0)\) with associated state \((\bar{y}, \bar{y}_f) = S_0(\bar{u}, \bar{u}_f) \in Y\). Then, by Theorem 3.5, for any sequence \(\{\alpha_n\} \subset (0, 1]\) with \(\alpha_n \searrow 0\) as \(n \to \infty\) and, for any \(n \in \mathbb{N}\), we can find an optimal pair \(((\bar{y}^\alpha_n, \bar{y}^\alpha_1_n), (\bar{u}^\alpha_n, \bar{u}^\alpha_1_n)) \in Y \times U_{ad}\) of the adapted optimal control problem \((P_{\alpha_n})\), such that the convergences \([3.19]–[3.22]\) hold true. Moreover, by Theorem 4.4 for any \(n \in \mathbb{N}\) there exist the corresponding adjoint variables \((\bar{p}^\alpha_n, \bar{p}^\alpha_1_n) \in Y\) to the problem \((P_{\alpha_n})\). We now derive some a priori estimates for the adjoint state variables \((\bar{p}^\alpha_n, \bar{p}^\alpha_1_n)\).

To this end, we introduce some further function spaces. At first, we put

\[
W(0, T) := \left( H^1(0, T; V^*) \cap L^2(0, T; V) \right) \times \left( H^1(0, T; V_1^*) \cap L^2(0, T; V_1) \right). \tag{4.13}
\]

Then we define

\[
W_0(0, T) := \{ (\eta, \eta_f) \in W(0, T) : (\eta(0), \eta_f(0)) = (0, 0_f) \}. \tag{4.14}
\]

Observe that both these spaces are Banach spaces when equipped with the natural norm of \(W(0, T)\). Moreover, \(W(0, T)\) is continuously embedded into \(C^0([0, T]; H) \times C^0([0, T]; H_1)\). We thus can define the dual space \(W_0(0, T)^*\) and denote by \(\langle \cdot, \cdot \rangle\) the duality pairing between \(W_0(0, T)^*\) and \(W_0(0, T)\). Note that if \((z, z_f) \in L^2(0, T; V^*) \times L^2(0, T; V_1^*)\), then we have that \((z, z_f) \in W_0(0, T)^*\) and it holds, for all \((\eta, \eta_f) \in W_0(0, T)^*\),

\[
\langle (z, z_f), (\eta, \eta_f) \rangle = \int_0^T \langle z(t), \eta(t) \rangle dt + \int_0^T \langle z_f(t), \eta_f(t) \rangle dt, \tag{4.15}
\]

with obvious meaning of \(\langle \cdot, \cdot \rangle\) and \(\langle \cdot, \cdot \rangle_T\). Next, we put

\[
Z := (L^\infty(0, T; H) \cap L^2(0, T; V)) \times (L^\infty(0, T; H_1) \cap L^2(0, T; V_1)), \tag{4.16}
\]

which is a Banach space when equipped with its natural norm.

We have the following result.

Lemma 4.6: Let the assumptions \((A1)–(A5)\) and \([2.17]–[2.13]\) be satisfied, and let

\[
(\lambda^\alpha_n, \lambda^\alpha_1_n) := (\varphi(\alpha_n) h''(\bar{y}^\alpha_n) \bar{p}^\alpha_n, \psi(\alpha_n) h''(\bar{y}^\alpha_1_n) \bar{p}^\alpha_1_n) \quad \forall n \in \mathbb{N}. \tag{4.17}
\]

Then there is some constant \(C > 0\) such that, for all \(n \in \mathbb{N}\),

\[
\| (\bar{p}^\alpha_n, \bar{p}^\alpha_1_n) \|_Z + \| (\partial_t \bar{p}^\alpha_n, \partial_t \bar{p}^\alpha_1_n) \|_{W_0(0, T)^*} + \| (\lambda^\alpha_n, \lambda^\alpha_1_n) \|_{W_0(0, T)^*} \leq C. \tag{4.18}
\]
Proof: In the following, \( C_i, i \in \mathbb{N} \), denote positive constants which are independent of \( \alpha_n \), by \( \bar{p}^{\alpha_n} \) and integrate over \([t, T]\) for any \( t \in [0, T)\). We obtain:

\[
-\frac{1}{2} \| \bar{p}^{\alpha_n}(T) \|_{H}^{2} + \frac{1}{2} \| \bar{p}^{\alpha_n}(t) \|_{H}^{2} - \frac{1}{2} \| \bar{p}_{T}^{\alpha_n}(T) \|_{H_T}^{2} + \frac{1}{2} \| \nabla \bar{p}^{\alpha_n}(t) \|_{L^2(t,T;H)}^{2} + \| \nabla \bar{p}^{\alpha_n} \|_{L^2(t,T;H)}^{2}
\]

First, we observe that the terms in the third line of the left-hand side of (4.19) are nonnegative, and, owing to (A2) and Lemma 2.3(i), the two integrals in the second line can be estimated by an expression of the form

\[
C_1 \left( \int_{t}^{T} \int_{\Omega} |\bar{p}^{\alpha_n}|^2 \, dx \, ds + \int_{t}^{T} \int_{\Gamma} |\bar{p}_{T}^{\alpha_n}|^2 \, d\Gamma \, ds \right).
\]

Now we recall that by Lemma 2.5 the sequence \( \{ \| (\bar{y}^{\alpha_n}, \bar{y}_{T}^{\alpha_n}) \|_{\mathcal{Y}} \} \) is bounded. Therefore, using the final time conditions (4.11), applying Young’s inequality appropriately, and then invoking Gronwall’s inequality, we find the estimate

\[
\| \bar{p}^{\alpha_n} \|_{L^\infty(0,T;H) \cap L^2(0,T;V)} + \| \bar{p}_{T}^{\alpha_n} \|_{L^\infty(0,T;H_T) \cap L^2(0,T;V_T)} \leq C_2 \quad \forall n \in \mathbb{N}.
\]

Next, we derive the bound for the time derivatives. To this end, let \( \( \eta, \eta_T \) \in \mathcal{W}_0(0, T) \) be arbitrary. As \( (\bar{p}^{\alpha_n}, \bar{p}_{T}^{\alpha_n}) \in \mathcal{Y} \), we obtain from integration by parts that

\[
\langle \langle \partial_t \bar{p}^{\alpha_n}, \partial_t \bar{p}_{T}^{\alpha_n} \rangle, (\eta, \eta_T) \rangle = \int_{0}^{T} \int_{\Omega} \partial_t \bar{p}^{\alpha_n} \eta \, dx \, dt + \int_{0}^{T} \int_{\Gamma} \partial_t \bar{p}_{T}^{\alpha_n} \eta_T \, d\Gamma \, dt
\]

\[
= -\int_{0}^{T} \langle \partial_t \eta(t), \bar{p}^{\alpha_n}(t) \rangle \, dt - \int_{0}^{T} \langle \partial_t \eta_T(t), \bar{p}_{T}^{\alpha_n}(t) \rangle \, d\Gamma \, dt
\]

\[
+ \int_{\Omega} \bar{p}^{\alpha_n}(T) \eta(T) \, dx + \int_{\Gamma} \bar{p}_{T}^{\alpha_n}(T) \eta_T(T) \, d\Gamma.
\]

Recalling the continuous embedding of \( \mathcal{W}(0,T) \) in \( C^0([0,T];H) \times C^0([0,T];H_T) \), and invoking (4.20), we thus obtain that

\[
\langle \langle \partial_t \bar{p}^{\alpha_n}, \partial_t \bar{p}_{T}^{\alpha_n} \rangle, (\eta, \eta_T) \rangle \leq \| \bar{p}^{\alpha_n} \|_{L^2(0,T;V)} \| \partial_t \eta \|_{L^2(0,T;V^*)}
\]

\[
+ \| \bar{p}_{T}^{\alpha_n} \|_{L^2(0,T;V_T)} \| \partial_t \eta_T \|_{L^2(0,T;V_T^*)} + \| \bar{p}^{\alpha_n}(T) \|_{H} \| \eta(T) \|_{H} + \| \bar{p}_{T}^{\alpha_n}(T) \|_{H_T} \| \eta_T(T) \|_{H_T}
\]

\[
\leq C_3 \| (\eta, \eta_T) \|_{\mathcal{W}_0(0,T)}, \quad (4.22)
\]
which means that
\[
\| (\partial_t \bar{p}^n, \partial_t \bar{p}_I^n) \|_{W_0^2(0,T)} \leq C_3 \quad \forall n \in \mathbb{N}.
\] (4.23)

Finally, comparison in (4.19) and in (4.10), invoking the estimates (4.20) and (4.23), yields that also
\[
\| (\lambda^n, \chi_I^n) \|_{W_0^2(0,T)} \leq C_4 \quad \forall n \in \mathbb{N},
\] (4.24)
and the assertion is proved.

We draw some consequences from Lemma 4.6. At first, it follows from (4.18) that there is some subsequence, which is again indexed by \( n \), such that, as \( n \to \infty \),
\[
(p^n, \bar{p}_I^n) \to (p, \bar{p}_I) \quad \text{weakly-star in } \mathcal{Z},
\] (4.25)
\[
(\lambda^n, \chi_I^n) \to (\lambda, \chi_I) \quad \text{weakly in } W_0^2(0,T)^*.
\] (4.26)
for suitable limits \((p, \bar{p}_I)\) and \((\lambda, \chi_I)\). Therefore, passing to the limit as \( n \to \infty \) in the variational inequality (4.12), written for \( \alpha_n, \ n \in \mathbb{N} \), we obtain that \((p, \bar{p}_I)\) satisfies
\[
\int_0^T \int_\Omega (p + \beta_4 \bar{u}) (v - \bar{u}) \, dx \, dt + \int_0^T \int_\Gamma (p_I + \beta_5 \bar{u}_I) \, (v_I - \bar{u}_I) \, d\Gamma \, dt \geq 0
\]
\[
\forall (v, v_I) \in \mathcal{U}_{ad}.
\] (4.27)

Next, we will show that in the limit as \( n \to \infty \) a limiting adjoint system for \((P_0)\) is satisfied. To this end, let \((\eta, \eta_I) \in W_0^2(0,T)\) be arbitrary. We multiply the equations (4.3) and (4.10), written for \( \alpha_n, \ n \in \mathbb{N} \), by \( \eta \) and \( \eta_I \), respectively. Integrating over \( Q \) and \( \Sigma \), respectively, using repeated integration by parts, and adding the resulting equations, we arrive at the identity
\[
\int_0^T \int_\Omega \lambda^n \eta \, dx \, dt + \int_0^T \int_\Gamma \lambda^n \eta_I \, d\Gamma \, dt + \int_0^T \langle \partial_t \eta(t), \bar{p}^n(t) \rangle \, dt + \int_0^T \langle \partial_t \eta_I(t), \bar{p}_I^n(t) \rangle \, dt
\]
\[
+ \int_0^T \int_\Omega \nabla \bar{p}^n \cdot \nabla \eta \, dx \, dt + \int_0^T \int_\Gamma \nabla \bar{p}_I^n \cdot \nabla \eta_I \, d\Gamma \, dt
\]
\[
+ \int_0^T \int_\Omega f''(\bar{y}^n) \, \bar{p}^n \eta \, dx \, dt + \int_0^T \int_\Gamma g''(\bar{y}^n) \, \bar{p}_I^n \eta_I \, d\Gamma \, dt
\]
\[
= \beta_3 \int_\Omega (\bar{y}^n(\cdot, T) - z_T) \eta(\cdot, T) \, dx + \beta_3 \int_\Gamma (\bar{y}^n_I(\cdot, T) - z_{\Gamma,T}) \eta_I(\cdot, T) \, d\Gamma
\]
\[
+ \beta_1 \int_\Omega (\bar{y}^n - z_Q) \eta \, dx \, dt + \beta_2 \int_\Gamma (\bar{y}^n_I - z_{\Sigma}) \eta_I \, d\Gamma \, dt.
\] (4.28)

Now, by virtue of the convergences (4.25), (4.26), we may pass to the limit as \( n \to \infty \) in
to obtain, for all \((\eta, \eta_T) \in W_0(0, T)\),

\[
\langle (\lambda, \lambda_T), (\eta, \eta_T) \rangle + \int_0^T \langle \partial_\eta \eta(t), p(t) \rangle \, dt + \int_0^T \langle \partial_{\eta_T} \eta_T(t), p_T(t) \rangle \, dt \\
+ \int_0^T \int_{\Omega} \nabla p \cdot \nabla \eta \, dx \, dt + \int_0^T \int_{\Gamma} \nabla_{\Gamma} p_T \cdot \nabla_{\Gamma} \eta_T \, d\Gamma \, dt \\
+ \int_0^T \int_{\Omega} f_{\Gamma}'(\bar{y}) \, p \eta \, dx \, dt + \int_0^T \int_{\Gamma} g_{\Gamma}'(\bar{y}_T) \, p_T \eta_T \, d\Gamma \, dt \\
= \beta_3 \int_\Omega (\bar{y}(\cdot, T) - z_T) \eta(\cdot, T) \, dx + \beta_3 \int_{\Gamma} (\bar{y}_T(\cdot, T) - z_{T,T}) \eta_T(\cdot, T) \, d\Gamma \\
+ \beta_1 \int_0^T \int_{\Omega} (\bar{y} - z_Q) \eta \, dx \, dt + \beta_2 \int_0^T \int_{\Gamma} (\bar{y}_T - z_{\Gamma}) \eta_T \, d\Gamma \, dt. \tag{4.29}
\]

Next, we show that the limit pair \(((\lambda, \lambda_T), (p, p_T))\) satisfies some sort of a complementarity slackness condition. To this end, observe that for all \(n \in \mathbb{N}\) we obviously have

\[
\int_0^T \int_{\Omega} \lambda_n^a \bar{p}_n^a \, dx \, dt = \int_0^T \int_{\Omega} \varphi(\alpha_n) h''(\bar{y}_n^a) |\bar{p}_n^a|^2 \, dx \, dt \geq 0.
\]

An analogous inequality holds for the corresponding boundary terms. We thus have

\[
\liminf_{n \to \infty} \int_0^T \int_{\Omega} \lambda_n^a \bar{p}_n^a \, dx \, dt \geq 0, \quad \liminf_{n \to \infty} \int_0^T \int_{\Gamma} \lambda_n \bar{p}_n^a \, d\Gamma \, dt \geq 0. \tag{4.30}
\]

Finally, we derive a relation which suggests that the limit \((\lambda, \lambda_T)\) should be concentrated on the set where \(|\bar{y}| = 1\) and \(|\bar{y}_T| = 1\) (which, however, we are not able to prove). To this end, we test the pair \((\lambda_n^a, \lambda_T^a)\) by \(((1 - (\bar{y}^a_n)^2) \phi, (1 - (\bar{y}_T^a)^2) \phi_T)\), where \((\phi, \phi_T)\) is any smooth test function satisfying \((\phi(0), \phi_T(0)) = (0, 0, T)\). Since \(h''(r) = \frac{2}{2 - r} - \frac{1}{2 - r^2}\), we obtain

\[
\lim_{n \to \infty} \left( \int_0^T \int_{\Omega} \lambda_n^a (1 - (\bar{y}^a_n)^2) \phi \, dx \, dt, \int_0^T \int_{\Gamma} \lambda_n^a (1 - (\bar{y}_T^a)^2) \phi_T \, d\Gamma \, dt \right) \\
= \lim_{n \to \infty} \left( 2 \int_0^T \int_{\Omega} \varphi(\alpha_n) \bar{p}_n^a \phi \, dx \, dt, 2 \int_0^T \int_{\Gamma} \psi(\alpha_n) \bar{p}_n^a \phi_T \, d\Gamma \, dt \right) = (0, 0). \tag{4.31}
\]

We now collect the results established above, especially in Theorem 3.5. We have the following statement.

**Theorem 4.7:** Let the assumptions (A1)–(A5) and (2.7)–(2.13) be satisfied, and let \(h\) be given by (1.11). Moreover, let \(((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T)) \in Y \times U_{ad}\), where \((\bar{y}, \bar{y}_T) = S_0(\bar{u}, \bar{u}_T)\), be an optimal pair for \((P_0)\). Then the following assertions hold true:
(i) For every sequence $\{\alpha_n\} \subset (0,1]$ with $\alpha_n \downarrow 0$ as $n \to \infty$, and for any $n \in \mathbb{N}$ there exists a solution pair $((\bar{y}^{\alpha_n}, \bar{y}^{\alpha_n}_T), (\bar{u}^{\alpha_n}, \bar{u}^{\alpha_n}_T)) \in Y \times U_{\text{ad}}$ to the adapted control problem $(\tilde{P}_{\alpha_n})$, such that (3.19)–(3.22) hold as $n \to \infty$.

(ii) Whenever sequences $\{\alpha_n\} \subset (0,1]$ and $((\bar{y}^{\alpha_n}, \bar{y}^{\alpha_n}_T), (\bar{u}^{\alpha_n}, \bar{u}^{\alpha_n}_T)) \in Y \times U_{\text{ad}}$ having the properties described in (i) are given, then the following holds true: to any subsequence $\{n_k\}_{k \in \mathbb{N}}$ of $\mathbb{N}$ there are a subsequence $\{n_k^{\ell}\}_{\ell \in \mathbb{N}}$ and some $((\lambda, \lambda_T), (p, p_T)) \in W_0(0,T)^* \times Z$ such that

- the relations (4.25), (4.26), (4.30), and (4.31) hold (where the sequences are indexed by $n_k^{\ell}$ and the limits are taken for $\ell \to \infty$), and
- the variational inequality (4.27) and the adjoint equation (4.29) are satisfied.

Remark 4.7: Unfortunately, we are not able to show that the limit pair $(p, p_T)$ solving the adjoint problem associated with the optimal pair $((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T))$ is uniquely determined. Therefore, it is well possible that the limiting pairs differ for different subsequences. However, it follows from the variational inequality (4.27) that for any such limit pair $(p, p_T)$ at least the orthogonal projection $\mathbb{P}_{U_{\text{ad}}}(p, p_T)$ onto $U_{\text{ad}}$ (with respect to the standard inner product in $H$) is uniquely determined; namely, we have

$$\mathbb{P}_{U_{\text{ad}}}(p, p_T) = (-\beta_4 \bar{u}, -\beta_5 \bar{u}_T).$$
