A NOTE ON OPTIMIZATION WITH MORSE POLYNOMIALS

LÊ CÔNG-TRINH

Abstract. In this paper we prove that the gradient ideal of a Morse polynomial is radical. This gives a generic class of polynomials whose gradient ideals are radical. As a consequence we reclaim a previous result that the unconstrained polynomial optimization problem for Morse polynomials has a finite convergence.

1. Introduction

Let us consider the unconstrained polynomial optimization problem

\[ f^* = \inf_{x \in \mathbb{R}^n} f(x), \quad (1.1) \]

where \( f \in \mathbb{R}[x_1, \cdots, x_n] =: \mathbb{R}[X] \) is a real polynomial in \( n \) variables \( x_1, \cdots, x_n \) whose degree is \( d \).

In principle polynomial optimization problems can be solved algorithmically by symbolic computation using algorithms from real algebraic geometry [2, 13]. Moreover, the optimization problem (1.1) is NP-hard even when \( d = 4 \) (cf. [12]).

A milestone in minimizing multivariate polynomials was given by J.-B. Lasserre (2001, [6]). He has introduced a sum of squares (SOS) relaxation for this problem by computing a lower bound for \( f^* \):

\[ f_{\text{sos}}^* := \max \gamma \quad \text{subject to } f(x) - \gamma \text{ is a SOS in } \mathbb{R}[X]. \quad (1.2) \]

Note that the SOS relaxation (1.2) can be solved by semidefinite programming (SDP). Moreover, it should be also noted that

\[ f^* = \max \quad \text{subject to } f(x) - \gamma \geq 0 \text{ for all } x \in \mathbb{R}^n. \]

Key words and phrases. Gradient ideal; Milnor number; Morse polynomial; Non-degenerate critical point; Polynomial optimization.

\(^1\)A sum of squares in \( \mathbb{R}[X] \) is a sum of the form \( \sum_{i=1}^{k} f_i^2 \), where \( k \in \mathbb{N} \) and \( f_i \in \mathbb{R}[X] \) for every \( i = 1, \cdots, k \).
Therefore $f^*_{\text{sos}} \leq f^*$, and the equality occurs if and only if $f - f^*$ is a SOS. In the case where $f^*_{\text{sos}}$ is strictly less than $f^*$, Lasserre proposed finding a sequence of lower bounds for $f(x)$ in some large ball \{x ∈ \mathbb{R}^n | ||x|| \leq R\}. This sequence converges to $f^*$ when the degrees of the polynomials introduced in the algorithm tend to infinity. However, it may not converge in finitely many steps, and moreover the degrees of the required auxiliary polynomials can be very large.

J. Nie, J. Demmel and B. Sturmfels (2006, [11]) have given a method to compute the global infimum $f^*$ which terminates in finitely many steps in terms of the gradient ideal $I_{\text{grad}}(f) = \langle \frac{\partial f}{\partial x_1}, \ldots, \frac{\partial f}{\partial x_n} \rangle$. The finite convergence of their SOS relaxation depends mainly on the SOS representation of $f - f^*$ modulo the gradient ideal $I_{\text{grad}}(f)$. More explicitly, for each natural number $N$, let us consider the problem

$$f^*_{N,\text{grad}} := \max_{\gamma} \gamma$$

subject to $f(x) - \gamma - \sum_{i=1}^{m} \phi_i(x) \frac{\partial f}{\partial x_i}$ is a SOS in $\mathbb{R}[X]$ and $\phi_i(x) \in \mathbb{R}[X]_{2N-d+1}$.

Here $\mathbb{R}[X]_m$ denotes the $(n+m)$-dimensional vector space of polynomials of degree at most $m$. Nie, Demmel and Sturmfels proved the following

**Theorem 1.1** ([11] Theorem 10). If $f$ attains its infimum $f^*$ over $\mathbb{R}^n$, then the sequence $\{f^*_{N,\text{grad}}\}_N$ converges increasing to $f^*$. Moreover, if the gradient ideal $I_{\text{grad}}(f)$ is radical, then there exists an integer $N$ such that $f^*_{N,\text{grad}} = f^*$.

It follows from Theorem 1.1 that the radicality of the gradient ideal $I_{\text{grad}}(f)$ is a sufficient condition for the finite convergence of the sequence $\{f^*_{N,\text{grad}}\}$. Moreover, for almost all polynomials $f$ in $\mathbb{R}[X]_d$ the gradient ideal $I_{\text{grad}}(f)$ is radical [11] Proposition 1], i.e. the ideal $I_{\text{grad}}(f)$ is generically radical.

In this paper we introduce a generic class of polynomials whose gradient ideals are radical - the class of Morse polynomials. Recall that a point $x^0 \in \mathbb{R}^n$ is called a critical point of a polynomial $f \in \mathbb{R}[X]$ if

$$\frac{\partial f}{\partial x_1}(x^0) = \cdots = \frac{\partial f}{\partial x_n}(x^0) = 0.$$ 

A critical point $x^0$ of the polynomial $f$ is said to be non-degenerate if the Hessian matrix\footnote{For a polynomial $f \in \mathbb{R}[x_1, \cdots, x_n]$, its Hessian matrix at a point $x^0 \in \mathbb{R}^n$ is defined by

$$\nabla^2 f(x^0) := \begin{bmatrix}
\frac{\partial^2 f}{\partial x_1^2}(x^0) & \cdots & \frac{\partial^2 f}{\partial x_1 \partial x_n}(x^0) \\
\vdots & \ddots & \vdots \\
\frac{\partial^2 f}{\partial x_n \partial x_1}(x^0) & \cdots & \frac{\partial^2 f}{\partial x_n^2}(x^0)
\end{bmatrix}.$$} $\nabla^2 f(x^0)$ of $f$ at $x^0$ is invertible. A polynomial $f \in \mathbb{R}[X]$ is called a Morse polynomial if all of its critical points are non-degenerate.
with distinct critical values. It is well-known from differential topology and singularity theory that almost all polynomial functions on \( \mathbb{R}^n \) are Morse (cf. \[1\]). Moreover, it was shown recently by Hà and Phạm \[5, Theorem 5.1\] that the set of Morse polynomials in \( \mathbb{R}[X] \) whose Newton polyhedra at infinity \( \mathcal{N}(f) \) contained in a convenient \( 4 \) Newton polyhedron at infinity \( \mathcal{N} \) is open and dense in \( \mathcal{N} \). Hence the class of Morse polynomials in \( \mathbb{R}[X] \) with a given convenient Newton polyhedron at infinity is large enough to consider for optimization.

The main result in this paper is the following

**Theorem 1.2.** Let \( f \in \mathbb{R}[X] \) be a Morse polynomial. Then its gradient ideal \( I_{\text{grad}}(f) \) is radical.

As a direct consequence of this theorem and Theorem 1.1, we get the following result which was obtained by the author in \[8\].

**Corollary 1.3.** Let \( f \in \mathbb{R}[X] \) be a Morse polynomial. Assume that \( f \) attains its infimum \( f^* \) over \( \mathbb{R}^n \). Then there exists an integer \( N \) such that \( f^*_{N, \text{grad}} = f^* \).

**Remark 1.4.** In Corollary 1.3 the assumption that \( f \) achieves a minimum on \( \mathbb{R}^n \) cannot be removed. In fact, let us consider the polynomial \( f(x, y) = x^2 + (xy - 1)^2 \in \mathbb{R}[x, y] \). It is easy to check that \( f \) has a single critical point at \((0, 0)\) which is non-degenerate. Hence \( f \) is a Morse polynomial. Moreover, since \( \lim_{y \to \infty} f(\frac{1}{y}, y) = 0 \), we have \( f^* = 0 \). But \( f \) does not attain the value 0 at any points in \( \mathbb{R}^2 \). On the other hand, we have

\[
f(x, y) - 1 = \frac{1}{2} x(1 - y^2) \frac{\partial f}{\partial x} + \frac{1}{2} y(1 + y^2) \frac{\partial f}{\partial y}.
\]

Therefore, it follows from the definition of \( f^*_{N, \text{grad}} \) in \(1.3\), with \( \phi_1(x, y) = \frac{1}{2} x(1 - y^2) \) and \( \phi_2(x, y) = \frac{1}{2} y(1 + y^2) \), that \( f^*_{N, \text{grad}} = 1 > 0 = f^* \) for every \( N \geq 3 \). This means that the sequence \( \{f^*_{N, \text{grad}}\}_N \) never converges to \( f^* \) in this case.

### 2. Proof of Theorem 1.2

In this section we give a proof for Theorem 1.2 applying some known results in singularity theory. Let \( f \in \mathbb{R}[X] \) be a Morse polynomial. Let us denote by

\[
V_{\text{grad}}(f) := \{x \in \mathbb{C}^n | \frac{\partial f}{\partial x_1}(x) = \cdots = \frac{\partial f}{\partial x_n}(x) = 0\}
\]

3 A set \( \mathcal{N} \) of the positive cone \( \mathbb{R}^+_n \) is called a Newton polyhedron at infinity if it is the convex hull in \( \mathbb{R}^n \) of the set \( A \cup \{0\} \), where \( A \subseteq \mathbb{N}^n \) is a finite set.

4 A polyhedron \( \mathcal{N} \subseteq \mathbb{R}^+_n \) is called convenient if it intersects each coordinate axis at a point different from the origin. For a polynomial \( f(x) = \sum u_x x^\alpha \) := \( \sum u_x x_1^{\alpha_1} \cdots x_n^{\alpha_n} \in \mathbb{R}[X] \), its Newton polyhedron at infinity \( \mathcal{N}(f) \) is defined by the convex hull in \( \mathbb{R}^n \) of the set \( \{\alpha | u_\alpha \neq 0\} \cup \{0\} \).
the set of complex critical points of $f$. Since $f$ is a polynomial, the set $V_{\text{grad}}(f)$ is actually an algebraic subset of $\mathbb{C}^n$ defined by the gradient ideal $I_{\text{grad}}(f)$.

**Lemma 2.1.** If $f$ is a Morse polynomial, then $V_{\text{grad}}(f)$ is finite.

*Proof.* It is well-known that each complex critical point of the Morse polynomial $f$ is isolated (cf. [10, Corollary 2.3]). Therefore the set $V_{\text{grad}}(f)$ is discrete. On the other hand, the set $V_{\text{grad}}(f)$ is algebraic in $\mathbb{C}^n$, hence it has only finitely many connected components (cf. [9, p.408]). Note that, each critical point itself is a connected component of the algebraic set $V_{\text{grad}}(f)$. This implies that $V_{\text{grad}}(f)$ has only finitely many elements. □

Assume $V_{\text{grad}}(f) = \{p^1, \ldots, p^N\}$, and let $p \in \mathbb{C}^n$ denote one of the points $p^i$. If $p = (p_1, \ldots, p_n) \in \mathbb{C}^n$, denote by $\mathbb{C}\{x_1 - p_1, \ldots, x_n - p_n\}$ the ring of convergent power series at the point $p$. The number

$$\mu(f, p) := \dim _{\mathbb{C}} \mathbb{C}\{x_1 - p_1, \ldots, x_n - p_n\}/I_{\text{grad}}(f)$$

is called the Milnor number of $f$ at $p$.

**Lemma 2.2.** $\mu(f, p)$ is finite.

*Proof.* The result follows from the Hilbert’s Nullstellensatz, since $p$ is an isolated critical point of $f$ (cf. [4, Lemma I. 2.3]). □

Denote

$$\mu(f) := \sum_{i=1}^{N} \mu(f, p^i) = \dim _{\mathbb{C}} \mathbb{C}[x_1, \ldots, x_n]/I_{\text{grad}}(f),$$

which is called the total Milnor number of $f$. It follows from Lemma 2.2 that $\mu(f)$ is finite.

The following result gives a relation between the number $|V_{\text{grad}}(f)|$ of complex critical points of $f$ and the total Milnor number of $f$, which yields also a criterion to check for radicality of the gradient ideal $I_{\text{grad}}(f)$.

**Lemma 2.3** ([3, Theorem 2.10]). $|V_{\text{grad}}(f)| \leq \dim _{\mathbb{C}} \mathbb{C}[x_1, \ldots, x_n]/I_{\text{grad}}(f)$, with equality if and only if the gradient ideal $I_{\text{grad}}(f)$ is radical.

To apply this lemma, we need to prove the following

**Lemma 2.4.** $\mu(f, p^i) = 1$ for every $i = 1, \ldots, N$.

*Proof.* Let us denote by $p$ one of the points $p^i$, $i = 1, \ldots, N$. By translating the variety accordingly, without loss of generality we may assume that $p$ is the origin $0 \in \mathbb{C}^n$. Consider the polynomial map

$$(f_1, \ldots, f_n) : \mathbb{C}^n \to \mathbb{C}^n,$$

where $f_i := \frac{\partial f}{\partial x_i} \in \mathbb{C}[x_1, \ldots, x_n]$, $i = 1, \ldots, n$. We have $f_i(0) = 0$ for all $i = 1, \ldots, n$. Moreover, we will show in the following that the determinant of the Jacobian matrix $J(f_1, \ldots, f_n)$ of this polynomial map at the origin
0 ∈ ℂ^n is non-zero. In fact, since f is Morse, we see that 0 is a non-degenerate critical point of f. It follows that the determinant of the Hessian matrix \( \nabla^2 f(0) \) of f at 0 is non-zero. Observe that

\[
\det J(f_1, \cdots, f_n)(0) = \det \begin{bmatrix}
\frac{\partial f_1}{\partial x_1}(0) & \cdots & \frac{\partial f_1}{\partial x_n}(0) \\
\vdots & \ddots & \vdots \\
\frac{\partial f_n}{\partial x_1}(0) & \cdots & \frac{\partial f_n}{\partial x_n}(0)
\end{bmatrix}
= \det \begin{bmatrix}
\frac{\partial^2 f}{\partial x_1^2}(0) & \cdots & \frac{\partial^2 f}{\partial x_1 \partial x_n}(0) \\
\vdots & \ddots & \vdots \\
\frac{\partial^2 f}{\partial x_n \partial x_1}(0) & \cdots & \frac{\partial^2 f}{\partial x_n^2}(0)
\end{bmatrix}
= \det \nabla^2 f(0).
\]

Hence \( \det J(f_1, \cdots, f_n)(0) \neq 0 \). It follows from the \textit{implicit function theorem} for convergent power series (cf. [4, Theorem I.1.18]) the following isomorphism of \( \mathbb{C} \)-vector spaces:

\[
\mathbb{C}\{x_1, \cdots, x_n\} / \langle f_1, \cdots, f_n \rangle \cong \mathbb{C}.
\]

This implies that \( \mu(f, 0) = \dim_\mathbb{C} \mathbb{C} = 1 \). \( \square \)

\textbf{Proof of Theorem 1.2} Assume that f is a Morse polynomial. Then it follows from Lemma 2.1 that \( V_{\text{grad}}(f) \) is a finite set whose elements are \( p^1, \cdots, p^N \). By Lemma 2.3, at each complex critical point \( p^i \) of f we have \( \mu(f, p^i) = 1 \). Hence

\[
\mu(f) = \sum_{i=1}^{N} \mu(f, p^i) = N = |V_{\text{grad}}(f)|.
\]

The theorem now follows from Lemma 2.3. \( \square \)

\textbf{Acknowledgements} The author would like to express his gratitude to Professor Hà Huy Vui for his valuable discussions on Morse theory and polynomial optimization. He would also like to thank the anonymous referees for their careful reading and detailed comments with many helpful suggestions.
