Transient receptor potential ankyrin 1 (TRPA1) is an ion channel involved in thermosensation and nociception. TRPA1 is activated by exogenous irritants and also by oxidants formed in inflammatory reactions. However, our understanding of its role in inflammation is limited. Here, we tested the hypothesis that TRPA1 is involved in acute inflammatory edema. The TRPA1 agonist allyl isothiocyanate (AITC) induced inflammatory edema when injected intraplantarly to mice, mimicking the classical response to carrageenan. Interestingly, the TRPA1 antagonist HC-030031 and the cyclo-oxygenase (COX) inhibitor ibuprofen inhibited not only AITC but also carrageenan-induced edema. TRPA1-deficient mice displayed attenuated responses to carrageenan and AITC. Furthermore, AITC enhanced COX-2 expression in HEK293 cells transfected with human TRPA1, a response that was reversed by HC-030031. This study demonstrates a hitherto unknown role of TRPA1 in carrageenan-induced inflammatory edema. The results also strongly suggest that TRPA1 contributes, in a COX-dependent manner, to the development of acute inflammation.
and mechanical cognisance. In addition, TRPA1 has been shown to mediate inflammatory and formalin-induced pain, irritating effects of pungent compounds and neurogenic inflammation. Also, mice treated with TRPA1 antagonists and TRPA1 knock out (KO) mice were found to develop a less severe ovalbumin-induced asthma reaction than untreated wild type (WT) mice. Topical treatment with mustard oil has been shown to induce local edema, an effect also blunted in TRPA1 deficient mice. However, it is still far from clear if TRPA1 has a role as a modulator of the inflammatory process.

In the present study, we investigated the possible role of TRPA1 in carrageenan-induced inflammatory paw edema which is a widely used model for investigating the acute inflammatory response and novel anti-inflammatory drugs. The results show that a substantial part of the mouse paw edema triggered by carrageenan is dependent on TRPA1. Furthermore, both carrageenan and AITC-induced edemas are to a large extent inhibited by ibuprofen. These findings highlight TRPA1 as a potential drug target for novel anti-inflammatory agents that could be a valuable alternative to cyclo-oxygenase (COX) inhibitors in the treatment of certain inflammatory conditions.

**Results**

Intraplantar (i.pl.) injection of carrageenan induced a substantial paw edema when measured at 3 h and 6 h following injection (Fig. 1A). The contralateral paw injected i.pl. with saline exhibited no measurable edema. Likewise, the TRPA1 agonist AITC evoked a severe edema when injected in the mouse paw (Fig. 1B).

To further study the role of TRPA1 in the inflammatory edema induced by carrageenan and AITC, we treated the mice with the selective TRPA1 antagonist HC-030031. The mice received 300 mg/kg of HC-030031 intraperitoneally (i.p.) 2 h before carrageenan or AITC was injected into the paw. HC-030031 treatment prevented carrageenan-induced inflammatory edema by 48% and 40% when measured at 3 h and 6 h following the carrageenan injection, respectively (Fig. 1A). As expected, HC-030031 reduced the AITC-induced edema response by 67% and 69% at 3 h and 6 h, respectively (Fig. 1B).

Next we used TRPA1-deficient mice to confirm and extend the results obtained with pharmacological blockade of TRPA1. We found that such mice developed on average 62% and 50% less edema as compared to WT mice when measured 3 h and 6 h following the i.pl. carrageenan injection (Fig. 2A). AITC induced a negligible edema in TRPA1 deficient mice (Fig. 2B) providing additional evidence that the AITC-induced response is indeed dependent on TRPA1.

The possible involvement of COX-derived prostanoids in TRPA1-mediated inflammatory edema was investigated by treating the animals with ibuprofen. Ibuprofen (100 mg/kg i.p.) given 2 h before carrageenan reduced the edema response by 51% and 49%, respectively when measured at 3 h and 6 h following carrageenan injection.

**Figure 1** | TRPA1 agonist allyl isothiocyanate (AITC) and carrageenan (Car) induced an inflammatory paw edema, which could be prevented by pre-treatment with HC-030031 (HC) or ibuprofen (Ibu.). HC-030031 (300 mg/kg) or ibuprofen (100 mg/kg) was injected intraperitoneally 2 h prior to intraplantar injection of carrageenan or AITC into the hind paw. The edema was measured 3 h and 6 h after intraplantar injection and compared to the basal level. The contralateral control paw injected with saline developed no measurable edema. Mean ± SEM, n=6, ***p<0.001.

**Figure 2** | In TRPA1 knock out (KO) mice, the carrageenan-induced paw edema formation was blunted when compared to the corresponding wild type (WT) mice (A). TRPA1-deficient mice showed almost no response to the TRPA1 agonist AITC (allyl isothiocyanate) in contrast to the WT mice (B). Carrageenan or AITC were injected intraplantarly. The edema was measured after 3 h and 6 h and compared to the basal level. The contralateral control paw injected with saline developed no measurable edema. Mean ± SEM, n=5, **p<0.01, ***p<0.001.
Likewise, the inflammatory edema evoked by AITC was also clearly inhibited by ibuprofen pre-treatment. The mean edema was about 60% less in ibuprofen treated than in vehicle treated mice at both 3 h and 6 h time points (Fig. 1B). These results indicate that prostanoids play an important role in mediating TRPA1-induced edema.

To further investigate the link between TRPA1 and COX, we transfected HEK 293 cells with human TRPA1. The COX-2 mRNA expression was up-regulated in TRPA1 transfected HEK 293 cells but not in non-transfected cells when they were exposed to AITC. HC-030031 given 30 min before AITC reduced the extent of the up-regulation of COX-2 mRNA triggered by TRPA1 stimulation (Fig. 3), supporting the concept that COX-derived prostanoids are involved in TRPA1-induced responses.

In addition, the direct activation of TRPA1 by carrageenan was investigated in HEK 293 cells expressing human TRPA1. In those cells, exposure to carrageenan (250 μg/ml) did not evoke a change in the basal calcium level, as measured by ratiometric calcium imaging, whereas subsequent addition of AITC (100 μM) always evoked robust calcium responses (Fig. 4). Higher concentrations of carrageenan could not be tested due to viscosity problems.

Discussion

The present study confirms the effects of exogenous TRPA1 agonists on edema formation and, more interestingly, reveals a hitherto unknown role of TRPA1 in carrageenan-induced inflammatory paw edema which is a widely used model for evaluating acute inflammation and anti-inflammatory drugs. The results strongly suggest that TRPA1 has a significant role in mediating the acute inflammatory response.

Previously, TRPA1 has been shown to mediate nociceptive processes in vivo, such as mechanical and cold hyperalgesia\(^30\)\(^-\)\(^31\), and also inflammatory pain\(^32\)\(^-\)\(^34\). A mutation in TRPA1 resulting in hyperfunction of the ion channel was recently associated with familial episodic pain syndrome\(^35\) highlighting the significant role of TRPA1 also in human pain. Although endogenous TRPA1 agonists are produced in inflammatory reactions\(^34\), very little is known about the possible role of TRPA1 in mediating inflammatory responses in addition to pain. Experiments conducted in knock out mice revealed that TRPA1 was involved in the pathogenesis of airway hyperreactivity and inflammation during ovalbumin-induced asthma\(^36\). Exposure to a TRPA1 agonist extracted from cigarette smoke was reported to cause tracheal edema which could be reversed by local administration of a TRPA1 antagonist whereas no edema formation occurred in TRPA1 KO animals\(^34\). In the present study, we observed that activation of TRPA1 by AITC resulted in inflammatory edema, and that a TRPA1-dependent...
The inflammatory edema following carrageenan injection involves both neurogenic and non-neurogenic mechanisms which have been strongly associated with prostaglandin production, COX-2 up-regulation and the formation of reactive nitrogen and oxygen species as well as cytokines and other inflammatory mediators. Many such pro-inflammatory agents can sensitize or activate TRPA1 either indirectly via G protein-coupled phospholipase C and protein kinase A pathways or by directly interacting with TRPA1. In the present study we showed that the TRPA1 antagonist HC-030031 clearly inhibited the development of carrageenan-induced edema while a direct TRPA1 agonist AITC evoked a carrageenan-like inflammatory response. To confirm our findings with the TRPA1 agonist and antagonist in acute inflammatory edema, we performed the experiments also in TRPA1 deficient animals. Indeed, the carrageenan-induced response was markedly attenuated in TRPA1 KO mice, and only a minor response to AITC was detected. When compared with previous reports on the acute phase of carrageenan-induced mouse paw edema, TRPA1 deficient mice showed a quantitatively similar attenuated response as mice lacking Akt143, endothelial nitric oxide-synthetase49 and the tumor necrosis factor α receptor 158,61. Taken together, our results support the conclusion that TRPA1 activation is involved in the pathogenesis of acute inflammatory edema in response to carrageenan.

Both mouse and human TRPA1 is inhibited by HC-030031, which is considered to be a selective TRPA1 antagonist as it is inactive on 48 other essential proteins involved in pain and inflammation including COX-2 and TRPV153,54. AITC is present in many naturally occurring plant-derived sources and has been shown to have antimicrobial43,44, cytostatic and cancer protective44 properties linked to multitudinous cellular targets. Whether TRPA1 mediates these effects is, however, unclear. As shown in the present study, AITC evoked edema in wild type but not in TRPA1 deficient animals, and in WT mice the AITC-response was inhibited by the TRPA1 antagonist HC-030031. These data together suggest that the AITC-induced edema response found in the present study was indeed mediated by TRPA1.

Given that TRPA1 is a highly promiscuous chemosensor5,45, one cannot rule out the possibility that TRPA1 may also recognize carrageenan. Due to its high viscosity, we could not test the direct effect of carrageenan in concentrations above 250 μg/ml on TRPA1. This concentration is 40–60 times lower than stock solutions normally used for intraplantar injections8 and 8 times lower than the concentration known to induce inflammation84. However, the injected carrageenan is quickly diluted within the tissue and hence the concentrations may well correspond to the in vitro test concentration that we found inactive at TRPA1 expressed in HEK 293 cells. Thus, we believe that the inflammation triggered by carrageenan is most likely not initiated by a direct interaction with TRPA1, but rather involves TRPA1 at some subsequent step in the inflammatory cascade.

The ability of ibuprofen to reduce both carrageenan and AITC-induced edema suggests that it inhibits COX downstream of TRPA1. Cellular calcium influx through TRPA1 would trigger the calcium-dependent release of prostaglandins and other pro-inflammatory agents that may further sensitize TRPA1 and increase its cell surface expression as occurs in sensory neurons47,48. It is also possible that TRPA1 activation increases prostaglandin production through enhanced COX-2 expression. This is supported by our in vitro finding that activation of TRPA1 by AITC can up-regulate the COX-2 transcript in HEK 293 cells. Accordingly, a significant role of [Ca2+]i in regulating COX-2 expression in macrophages was recently reported53. Together these events would generate and maintain a TRPA1 and COX-dependent inflammation. Our finding that the TRPA1 antagonist HC-030031 is as effective as the COX inhibitor ibuprofen to inhibit the development of carrageenan and AITC-induced edema is promising, and may help to develop safer anti-inflammatory drugs than existing COX inhibitors.

An interesting question remains on the mechanisms behind TRPA1-mediated inflammatory edema which may involve neurogenic and/or non-neurogenic components. TRPA1 activation inafferent nerve endings may lead to a focal release of bioactive compounds such as calcitonin gene-related peptide (CGRP) and substance P which play a major role in neurogenic inflammation and exert vascular effects which may contribute to the formation of inflammatory edema. However, spinal TRPA1 may also regulate the peripheral responses through retrograde afferent signaling52. In addition, activation of TRPA1 on vascular sensory neurons and/or endothelium50 can lead to vasodilatation and increased vascular permeability and edema formation51. Since endothelium is also a known source of vasodilating and edema-evoking prostaglandins and other prostanooids, this could provide an explanation for the link between TRPA1 and COX, as observed in the present study.

In humans, TRPA1 is present on nociceptive nerve endings and in non-neuronal cells such as keratinocytes and fibroblasts, from which prostaglandins and other mediators may be released after TRPA1 activation52,53. Therefore, the mouse carrageenan-induced paw edema may be a useful model to identify novel compounds and drugs targeting TRPA1 in humans.

Our study demonstrates a significant role for TRPA1 in the development of acute inflammation, and suggests that TRPA1 antagonists may have anti-inflammatory properties in addition to their previously recognized analgesic effects in inflammatory pain.

Methods
Wild type and TRPA1-deficient C57BL/6 mice were used in the experiments. TRPA1-deficient mice and the corresponding WT mice were originally obtained from Dr David Julius (UCSF) and back-crossed in the laboratory of EDH and PMZ. AITC was purchased from Drp (St Louis, MO, USA) and injected ad libitum. Edema was measured before and 3 h after carrageenan or AITC injection using a plethysmometer (Ugo Basile, Comerio, Italy). Edema is expressed as the difference between the carrageenan or AITC treated paw at the time indicated and the basal level.

HEK 293 human embryonic kidney cells (American Type Culture Collection, Manassas, VA, USA) were cultured in Eagle’s Minimum Essential Medium (EMEM) supplemented with 10% heat-inactivated fetal bovine serum, sodium bicarbonate (1.5%), sodium pyruvate (1 mM), non-essential amino acids (1 mM each) (all from Lonza, Verviers, Belgium), penicillin (100 U/ml), streptomycin (100 μg/ml) and amphotericin B (the last three compounds from Invitrogen, Paisley, UK) at 37 °C in 5% CO2. The cells were transfected using 0.42 μg/cm² human TRPA1 plasmid DNA (pCMV6- XL4 from Origene Rockville, MD, USA) with Lipofectamine 2000 (Invitrogen) according to the manufacturer’s directions. After 24 h of transfection, HC-030031 (10 μM) or solvent (control) was added to the cells in fresh culture medium 30 min prior to the activation of TRPA1 by AITC (10 μM). The cells were then incubated for 6 h before being harvested for RNA extraction. Similar experiments were carried out by using non-transfected (wild type, WT) HEK 293 cells.

Total RNA extraction was carried out with the use of GenElute Mammalian Total RNA Miniprep Kit (Sigma). Reverse-transcription of RNA to cDNA and quantitative RT-PCR reactions were performed as previously described44. TRPA1 expression was measured by using TaqMan Gene Expression Assay (Applied Biosystems, Foster City, CA, USA). COX-2 and GAPDH primers and probes were identical to those previously described44. COX-2 mRNA levels were normalized against GAPDH.

Fluorometric calcium imaging was used to study the effect of carrageenan on human TRPA1 expressed in HEK 293 cells. The cells were plated in 96-well black-walled plates (Costar, Cambridge, MA, USA) and loaded with Fura 2-AM (1 μM,
Involvitis), probenecid (2 mM, Sigma Chemical Co.) and plumericin acid (20%, Involvitis) for 1 h at 37 °C. The cells were then washed with physiological buffer solution (PBS), containing 140 mM NaCl, 5 mM KCl, 10 mM glucose, 10 mM HEPES, 2 mM CaCl2 and 1 mM MgCl2, and allowed to equilibrate for a period of 30 min in the dark before the start of the experiments. The intracellular calcium concentration was determined at 25 °C in a Flexstation 3 (Molecular Devices, Sunnyvale, CA, USA) with excitation wavelengths of 340 nm and 380 nm and changes were detected by a dye emission ratio (λ ratio) determined at various times after compound addition.

Results are expressed as mean ± standard error of mean (SEM). Statistical analysis was carried out by using Student’s t-test or one-way ANOVA with Bonferroni’s multiple comparisons test and results were considered significant at *p < 0.05, **p < 0.01 and ***p < 0.001.

Acknowledgements

We wish to thank Ms Petra Mikkulainen for technical assistance and Mrs Heli Määttä for secretarial help. The study was supported by grants from the Medical Research Fund of Tampere University Hospital, Finland; Tampere Tuberculosis Foundation, Finland; the Medical Faculty of Lund (ALF) and the Swedish Research Council (2007–3095, 2010–3347). The authors thank Peter McIntyre, University of Melbourne, for providing the human TRPA1-inducible cell line.

Author contribution

LJM participated in the animal and laboratory experiments, calculated the results and statistics and drafted the manuscript. ML, MK, RK, TL, and RMN participated in the animal and the laboratory experiments. EDH and PMZ provided the TRPA1 knock out and corresponding wild type animals and carried out the calcium imaging experiments. EM conceived and supervised the study and helped to draft the manuscript. All authors were involved in the planning of the study and in writing the manuscript.
