Abstract: This research aims to form polymer matrix composites (PMCs) between calcium aluminosilicate (CaNaAlSi2O7) as a dispersed phase made from eggshells as the raw material via the sol-gel process and polyurethane foam (PU) as a matrix. The received PMCs samples were characterized phase formation by X-ray diffraction (XRD), microstructure by scanning electron microscopy, pore size and specific surface area by brunauer-emmett-teller (BET), mechanical properties by compression test, the functional groups by the Fourier transform infrared spectroscopy (FTIR), and the endothermic-exothermic reaction by differential thermal analysis (DTA). The CaNaAlSi2O7 acted as a dispersant in the polyurethane (PU) matrix, (PMCs). The best composition of composite materials is adding 10 vol% CaNaAlSi2O7 into PU matrix. The average particle size of CaNaAlSi2O7 is approximately 10 μm, non-agglomeration, and good dispersion in the entire volume of PU foam. The composite foam cells are well ordered and uniform in size and shape. The true density, elastic modulus and compressive strength of CaNaAlSi2O7/PU composites are 1.47 g/cm³, 0.0327 Kgf/mm², and 0.0188 Kgf/mm², respectively. The CaNaAlSi2O7/PU composites are semi-crystalline phase formation between tetragonal phase formations of CaNaAlSi2O7 and amorphous phase formation of PU.

Key words: Polymer matrix composites, eggshells, calcium aluminosilicate, catalyst, specific surface area.

1. Introduction

Over 200 years ago, a Swedish scientist discovered the first of a group crystalline microporous aluminosilicate known as zeolite; zeolite derived from Greek word “Zeo” which means boil and “Lithos” means stone [1]. Zeolite consists of open cells, three dimensional framework of tetrahedral AlO₄⁻ and SiO₄⁻ units linked through shared oxygen molecules, crystalline microporous and aluminosilicate minerals. Due to their properties that have size and shape selectivity, so its applications can be used in ion-exchange, purification, desiccant or adsorbent, and as a catalyst. The catalysts are quite important in chemical, petrochemical, and oil refining industries.

The calcium sodium aluminosilicate is one kind of zeolites which can be synthesized from many methods such as electrostatic deposition, sol-gel process [2], mixed matrix membranes (MMM) as a promising morphology for gas separation and as a polymer matrix composite, for example, separation of xylene mixtures using polyurethane-zeolite composite membranes [3]. Because polyurethane (PU) has many good properties such as moisture resistance, high shear strength, excellent sound absorption, vibration resistance, and oscillation environment tolerance [4], several researches have used their benefit with homogeneous pore cells in order to improve their researches. The present study is using polyurethane (PU) foams as a matrix for making catalyst composite foams.

This research aims to produce catalyst composite foams between calcium sodium aluminosilicate (CaNaAlSi2O7) as a dispersed phase made from eggshells as the raw material via the sol-gel process and polyurethane foam (PU) as a matrix. The constituent of eggshells contained 1 wt% of magnesium carbonate, 4 wt% of calcium phosphate...
and organic matter, and mainly 94 wt% of calcium carbonate. The eggshell is an important source of calcium oxide as a raw material to prepare the catalyst powder [5].

2. Experiments

2.1 Calcium Chloride Solution Preparation

Calcium oxide (CaO) was prepared from eggshells by the following steps, washed with tap water and dried at room temperature, crushed and calcined under atmospheric pressure at 900 °C for 1 h with a heating rate of 10 °C/min, then 0.5 g of air cooled CaO powder was dissolved in 20 mL of 1 M HCl (Analytical Reagent, AR, Lab-Scan Co., Ltd., Thailand) to obtain the CaCl2 solution [2].

2.2 Sodium Aluminosilicate Solution Preparation

Sodium aluminosilicate solution was obtained by mixing 0.8 g of fumed silica powder (SiO2, WACKER Chemie, AG, Germany), 5.0 g of precipitated sodium aluminosilicate (United Silica, Siam Ltd, Thailand), and 1.0 g of sodium hydroxide (NaOH, Molecule Co., Ltd., Thailand) with 20 mL distillated water [2].

2.3 Synthesis of Calcium Sodium Aluminosilicate

The calcium sodium aluminosilicate (CaNaAlSi2O7) was obtained by pouring the mixture solution of 2.1 into the mixture solution of 2.2 stirred then left at room temperature for 24 h, via the sol-gel process [2]. The gel sample was dried at 110 °C for 24 h (dried gel at 110 °C) and calcined the dried gel at 300 °C for 1 h (catalyst powder at 300 °C) to obtain CaNaAlSi2O7 powder.

2.4 CaNaAlSi2O7-PU Catalyst Foams

PMCs preparation was prepared by using polyurethane foams (PU) as a template (DALTOPED®FF 45804 and SUPRASEC®2749 from Huntsman (Thailand)). The FF 45804 is polyol and the SUPRASEC 2749 is di-isocyanate used as pre-polymer. The weight ratio between FF 45804 and SUPRASEC 2749 is 100:98. The PMCs were prepared by stirring the FF 45804 with a speed of 1,200 rpm for 3 min then added 10 vol% of catalyst gel into the FF 45804, after that adding the SUPRASEC 2749 rapidly into the mixture. The mixture stirred uniformly until to complete exothermic reaction to obtain the catalyst foams.

3. Results and Discussion

The thermal stability of catalyst and PU composite foams was determined by the differential thermal analysis (DTA, Perkins-Elmer TAC7/DX, DTA7, USA) under a nitrogen atmosphere as shown in Fig. 1. The samples were heated from 30 °C to 950 °C with a heating rate 10 °C/min. The result shows an exothermic reaction of PU foams started to degrade from 530 °C to 650 °C as shown in Fig. 1a. Furthermore, the catalyst-composite foams added 10 vol% catalyst powder (calcined at 300 °C) have an endothermic peak at 790 °C and onset at 786 °C due to re-crystalline of catalyst gel in PU foam matrix as shown in Fig. 1b.

The data of true density values of dried gel at 110 °C, catalyst powder (dried gel calcined at 300 °C), pure PU foams, and PU foams added 10 vol% catalyst powder (dried gel and calcined at 300 °C) were analyzed by the gas pycnometer, as shown in Table 1.
Table 1  True density values.

| Sample names                                           | True density (g/cm³) |
|-------------------------------------------------------|----------------------|
| Catalyst dried gel at 110 °C                         | 1.90                 |
| Catalyst powder (dried gel and calcined at 300 °C)    | 1.96                 |
| Pure PU foams                                         | 1.13                 |
| PU foams added 10 vol% catalyst powder (dried gel and calcined at 300 °C) | 1.47                 |

Table 2  BET analysis of catalyst samples.

| Sample codes                                           | Specific surface area (m²/g) | Total pore volume (cm³/g) | Average pore diameter (Å) |
|-------------------------------------------------------|-------------------------------|---------------------------|---------------------------|
| Catalyst dried gel at 110 °C                         | 37.91                         | 0.2917                    | 307.8                     |
| Catalyst powder (dried gel and calcined at 300 °C)    | 38.89                         | 0.3728                    | 383.4                     |

Adding 10 vol% catalyst powder (dried gel and calcined at 300 °C) into pure PU foams can increase the true density values of composite foams from 1.13 to 1.47g/cc. The data of specific surface area, total pore volume, and average pore diameter of dried gel and catalyst powder were analyzed as tabulated in Table 2. The catalyst powder (dried gel and calcined at 300 °C) exhibited surface area, pore volume and pore diameter values higher than the data values of dried gel at 110 °C because internal voids in the material caused by generating of carbon dioxide (CO₂). Therefore, the catalyst powder has high values of specific surface area, pore volume, and pore diameter.

The XRD peak pattern of eggshells is consistent with the International Center for Diffraction Data (JCPDS) number of 01-085-1108 expressed 2θ and (hkl) values equal to 29.47 (104), 36.04 (110), 39.49 (113), 43.24 (2302), 47.69 (018), 48.62 (116) and 48.62 (122), indicating the rhombohedral phase formation of calcium carbonate (CaCO₃) as shown in Fig. 2a.

Fig. 2b shows a peak pattern of CaO, consistent with the JCPDS number of 00-037-1497 at 2θ and (hkl) equal to 32.61 (111), 37.35 (200), 53.86 (220), 64.15 (311), 67.38 (222) and 79.67 (400) indicating the cubic phase formation. Furthermore, both Figs. 2c and 2f demonstrated peak patterns of dried gel at 110 °C and catalyst powder (dried gel and calcined at 300 °C) consistent with the JCPDS numbers of 01-076-0479 and 01-071-2066 at 2θ and (hkl) equal to 31.81 (211), 45.43 (220), 56.45 (222), 29.31 (201), 68.71 (521), and 75.26 (420), indicating the tetragonal phase formation of calcium sodium aluminosilicate.

Fig. 3 shows the XRD peak pattern comparison between pure PU foams and catalyst composite foams. The step scan were used to present time at 1 s with 2θ = 5°-80°. The XRD peak patterns of pure PU foams and catalyst composite foams exhibited amorphous regions, so the step scan measured in the range of 2θ = 5°-80°. However, the XRD peak patterns of CaNaAlSi₂O₇ powder show crystalline phase in the range of 2θ equal to 25°-35° as shown in Fig. 4. The peak patterns of Figs. 4b-4e were demonstrated at 2θ about 32° which indicated the tetragonal formation of calcium sodium aluminosilicate.

Fig. 5a shows the FT-IR (Perkin Elmer, Spectrum one) spectrum of CaO prepared from eggshells calcination.
Preparation of Calcium Aluminosilicate Catalyst Foams from Eggshells and Polyurethane Template

The wave number of peak at 3,642.13 cm$^{-1}$ belongs to $\nu$-OH of Ca(OH)$_2$ due to moisture absorption of CaO. The broad band peak occurs around 1,440.33 cm$^{-1}$ corresponding to the Ca-O. Figs. 5b and 5c are the FTIR spectra of catalyst which dried gel at 110 °C, and catalyst powder (dried gel and calcined at 300 °C) show at 500-550 cm$^{-1}$ indicating Al-O-C, Si-O-Al, Si-O, and Si-O-Si bonding consistent with the data reported [2].

In addition, the FTIR spectra at 794.40, and 1,446.04 cm$^{-1}$ show the characteristics of the $\beta$-Ca-O-Si, Ca-O-Si, and strong C=O vibration, respectively, which indicated the CaNaAlSi$_2$O$_7$.

Figs. 5d, 5e and 5f show the FTIR spectra comparison of PU foams added 10 vol% catalyst dried gel at 110 °C, PU foams added 10 vol% catalyst powder (dried gel and calcined at 300 °C), and pure PU foams.

The PU foams added 10 vol% catalyst dried gel at 110 °C show peak positions at 470.89 and 797.20 cm$^{-1}$, same as the peak positions of the PU foams added 10 vol% catalyst powder (dried gel and calcined at 300 °C) at 463.43 and 794.40 cm$^{-1}$ corresponding to the characteristics of $\beta$-Ca-O-Si and Ca-O-Si, respectively.

The FTIR spectra of the pure polyurethane foams prepared from the FF 45804 and the SUPRASEC 2749 are shown in Fig. 5f. This spectrum indicates peak positions belonging to polyurethanes at 3,437.71 cm$^{-1}$.
consistent with -N-H stretching vibration of urethane groups (3,200-3,450 cm\(^{-1}\)) [4]. The broad band peak at 2,800-3,000 cm\(^{-1}\) corresponds to -C-H stretching [6]. They do not show the peak position at 2,250-2,270 cm\(^{-1}\) consistent with the characteristic of isocyanate (\(\text{-N=O}\)) group because of polymerization [6, 8]. The \(-\text{C} = \text{O}\) stretching of the urethane carbonyl peak at 1,712.90 and 1,730.79 cm\(^{-1}\) are observed and reported at 1,702-1,737 cm\(^{-1}\) [7]. The peak at 1,613.45 cm\(^{-1}\) indicates the carbonyl vibration (\(-\text{C} = \text{O}\)) reported at 1,630-1,637 cm\(^{-1}\) [6, 8] while -NH bending is identified peak at 1,512.21 cm\(^{-1}\). Also, the peak position at 1,541.65 cm\(^{-1}\) originates from the coupling of \(-\text{CN}\) stretching and \(-\text{NH}\) bending [9]. The FTIR peaks observed between 1,400 and 1,480 cm\(^{-1}\) (in this work occurred at 1,414.57 and 1,453 cm\(^{-1}\)) are attributed to \(-\text{CH}_2\) scissoring vibrations. The small peaks at 1,345.96 and 1,374.99 are connected to the wagging vibrations of methylene groups, whereas the peak at 1,310.32 cm\(^{-1}\) is assigned to \(-\text{CH}_2\) twisting. The FTIR spectra exhibit the characteristic peak at 1,000-1,400 cm\(^{-1}\) of C-N and C-O stretching. The presence of the FTIR peaks belongs to polyurethane foams.

Fig. 6 shows the SEM photographs analyzed by the scanning electron microscope (SEM) (Philips, XC, Netherland) of pure PU foams and pure PU foams added with 10 vol% catalyst powder (dried gel and calcined at 300 °C). The cell edges and cell walls of pure PU foams are distinctly visible with almost uniform cell structures throughout as shown in Figs. 6a, 6b and 6c. Cell size measured by SEM is approximately 200-250 μm. The samples added with 10 vol% catalyst powder (dried gel and calcined at 300 °C) are shown in Figs 6d, 6e, and 6f. The 15 vol%, 20 vol%, 30 vol%, and 50 vol% of catalyst powder (dried gel and calcined at 300 °C) were added into PU foams. The excess volume percentage of catalyst added into PU foams is not good for making catalyst composite foam formation due to the agglomeration of catalyst particles within the interconnecting cells of PU foams. Therefore, the best composition of composite materials is adding 10 vol% CaNaAlSi\(_2\)O\(_7\) into PU matrix with uniform structure and non-agglomeration of catalyst powder. The composite foam cells still are well ordered and uniform in size and shape. However, open cells of the composite foam seem smaller than that of pure PU foams. According to the SEM image results of catalyst composite foams which added 10 vol% catalyst dried gel at 110 °C into PU foam matrix are similar SEM micrographs of catalyst composite foams added with 10 vol% catalyst powder (dried gel and calcined at 300 °C) into PU foam matrix.

The compressive strength and elastic modulus of PU foams added 10 vol% catalyst powder (dried gel and calcined at 300 °C) compared to pure PU foams were measured by a compressive testing instrument (Qmat 5.44 M-Series-10 KM) according to ASTM D 695 compression of rigid plastics. The dimensions of are 25.4 × 25.4 × 12.7 mm\(^3\) and the crosshead speed of compression was set at 1.2 mm/min. The elastic
modulus and compressive strength of the composite foams are $0.0327 \pm 0.0078$ and $0.0188 \pm 0.0017$ Kgf/mm$^2$, respectively. The elastic modulus and compressive strength of pure PU foams are $0.1162 \pm 0.047$ and $0.0245 \pm 0.0067$ Kgf/mm$^2$, respectively. The mechanical properties (elastic modulus and compressive strength) of catalyst composite foams added catalyst powder (dried gel and calcined at 300 °C) are less than that of pure PU foams due to H-bond formation among urethane groups that greatly contributes to the strength and modulus of PU foam, for the reason of catalyst powder (dried gel and calcined at 300 °C) may intervene with the H-bond formation and no strong interaction or graft within PU matrix. Therefore, the pure PU foams have high elastic modulus and compressive strength. Furthermore, catalyst composite foams have high specific surface area, thermal resistance, and corrosion resistance useful for using as catalyst composite foams.

4. Conclusions

The catalyst foam was successfully made from eggshells as the raw material of calcium sodium aluminosilicate catalyst via the sol-gel process to prepare PMCs. The CaNaAlSi$_2$O$_7$/PU composites have potential as catalyst composite foams in the chemical and petrochemical industries functioned as ion exchange, filter, and desiccant.
