UNCONDITIONAL BASES FOR HOMOGENEOUS
\(\alpha\)-MODULATION TYPE SPACES

MORTEN NIELSEN

ABSTRACT. In this article we construct orthonormal bases compatible with bi-variate homogeneous \(\alpha\)-modulation spaces and the associated spaces of Triebel-Lizorkin type. The construction is based on generating a separable \(\alpha\)-covering and using carefully selected tensor products of univariate brushlet functions with regards to this covering. We show that the associated systems form an unconditional bases for the homogeneous \(\alpha\)-spaces of Triebel-Lizorkin type.

1. INTRODUCTION

Unconditional bases for smoothness spaces play an important role for many applications as the bases often provide simple characterizations of the space in terms of certain sparseness conditions. For example, smoothness measured in a Besov space is equivalent to a certain sparseness of a wavelet expansion [17]. Moreover, norm characterizations often allow us to identify certain smoothness spaces as nonlinear approximation spaces [11,14]. As a consequence we gain a better understanding of how to compress smooth functions by using the sparse representation of the function in the unconditional basis [7,8].

The \(\alpha\)-modulation spaces \(M_{p,q}^{s,\alpha}(\mathbb{R}^d), \alpha \in [0, 1]\), form a parameterized family of smoothness spaces defined on \(\mathbb{R}^d\) that include the Besov and modulation spaces as special cases, corresponding to \(\alpha = 1\) and \(\alpha = 0\), respectively. The spaces are built from the same type of scheme arising from different segmentations of the frequency space. The \(\alpha\)-parameter determines the nature of the segmentation. For example, the Besov spaces (\(\alpha = 1\)) correspond to a dyadic segmentation of the frequency space, while the modulation spaces (\(\alpha = 0\)) correspond to a uniform covering. The intermediate cases correspond to “polynomial type” segmentations of the frequency space. The classical \(\alpha\)-modulation spaces are inhomogeneous spaces in the sense that the underlying segmentation of the frequency space cover the zero-frequency (so a natural low-pass filter is integrated in the representation). Recently, however, the \(\alpha\)-modulation spaces have been extended to a homogeneous setup. The main contribution of of this note is to present a construction of unconditional bases for homogeneous \(\alpha\)-modulation spaces.

The \(\alpha\)-modulation spaces were introduced by Gröbner [12], and it was pointed out by Feichtinger and Gröbner [9,10] that Besov and modulation spaces are special cases of an abstract construction, the so-called decomposition type Banach spaces.
The coverings giving rise to α-modulation spaces have also been considered by Päivärinta and Somersalo in [19] as a tool to study pseudo-differential operators. The close connection between decomposition spaces and classical smoothness space such as modulation spaces was first pointed out by Triebel [23]. Triebel’s work later inspired a more general treatment of decomposition smoothness spaces [5, 6]. Another benefit of the connection to the general theory of decomposition spaces is that one can easily construct associated smoothness spaces of Triebel-Lizorkin type (α-TL spaces).

The main contribution of the present paper is to offer a construction of an orthonormal basis for $L_2(\mathbb{R}^2)$ that extends to an unconditional basis for bi-variate α-modulation spaces. We believe that our construction is the first example of a non-redundant representation system for multivariate α-TL spaces. Orthonormal bases for classical (inhomogeneous) α-modulation spaces were constructed by the author in [18]. This construction was later extended to anisotropic bi-variate setting by Rasmussen [21].

The orthonormal basis is constructed using a carefully calibrated tensor product approach based on so-called univariate brushlet systems. Brushlets are the image of a local trigonometric basis under the Fourier transform, and such systems were introduced by Laeng [15]. Later Coifman and Meyer [16] used brushlets as a tool for image compression. In [3], Borup and Nielsen used the freedom to choose the frequency localization of a brushlet system to construct (orthonormal) unconditional brushlet bases for the univariate α-modulation spaces. Using the orthonormal basis for bi-variate α-modulation spaces, we give a characterization of the bi-variate α-modulation spaces in terms a sparseness condition on the expansion coefficients, and we also identify the α-modulation spaces as approximation spaces associated with nonlinear $m$-term approximation.

2. BI-VARIATE BRUSHLET BASES

Given an orthonormal basis $\{f_k\}_k$ for $L_2(\mathbb{R})$, a universal method to create an associated orthonormal basis for $L_2(\mathbb{R}^2)$ is to consider the tensor product basis $\{f_k \otimes f_{k'}\}_{k,k'}$. While this works very well for e.g. the trigonometric system on a cube, the straightforward tensor product approach can be considered more problematic for wavelets and similar systems as basis elements with long “skinny” support in the frequency plane are created. Such elements are not well-adapted for analysis of classical isotropic smoothness spaces such as Besov or Triebel-Lizorkin spaces.

In this section we wish to avoid creating elements with “skinny” support in frequency, but still use a tensor product construction to obtain an orthonormal basis for $L_2(\mathbb{R}^2)$. We will accomplish this by modifying the tensor product construction carefully by keeping track of the shape of the system in the frequency plane by extracting subsystems from a sequence of so-called univariate brushlet bases. We also mention that the analysis later in the paper would have been much simplified if one could have used localised orthonormal exponential basis. But, unfortunately, this is not possible due to the Balian-Low theorem.

To keep the notation manageable, we consider only the bi-variate case in this note, but the reader can verify that the basic idea behind the construction can be adapted to the general multivariate case.
2.1. Univariate brushlets. We begin by introducing brushlet in a univariate setting. Each univariate brushlet basis is associated with a partition of the frequency axis. The partition can be chosen with almost no restrictions, but in order to have good properties of the associated basis we need to impose some growth conditions on the partition. We have the following definition.

**Definition 2.1.** A family $\mathcal{I}$ of intervals is called a **disjoint covering** of $\mathbb{R}$ if it consists of a countable set of pairwise disjoint half-open intervals $I = [\alpha_I, \alpha'_I)$, $\alpha_I < \alpha'_I$, such that $\bigcup_{I \in \mathcal{I}} I = \mathbb{R}$. If, furthermore, each interval in $\mathcal{I}$ has a unique adjacent interval in $\mathcal{I}$ to the left and to the right, and there exists a constant $A > 1$ such that

$$A^{-1} \leq \frac{|I|}{|I'|} \leq A, \quad \text{for all adjacent } I, I' \in \mathcal{I},$$

we call $\mathcal{I}$ a **moderate disjoint covering** of $\mathbb{R}$.

Given a moderate disjoint covering $\mathcal{I}$ of $\mathbb{R}$, assign to each interval $I \in \mathcal{I}$ a cutoff radius $\varepsilon_I > 0$ at the left endpoint and a cutoff radius $\varepsilon'_I > 0$ at the right endpoint, satisfying

\[
\begin{aligned}
(i) & \quad \varepsilon'_I = \varepsilon_I' \text{ whenever } \alpha'_I = \alpha_I' \\
(ii) & \quad \varepsilon_I + \varepsilon'_I \leq |I| \\
(iii) & \quad \varepsilon_I \geq c|I|,
\end{aligned}
\]

with $c > 0$ independent of $I$.

We are now ready to define the brushlet system. For each $I \in \mathcal{I}$, we will construct a smooth bell function localized in a neighborhood of this interval. Take a non-negative ramp function $\rho \in C^\infty(\mathbb{R})$ satisfying

\[
\rho(\xi) = \begin{cases} 0 & \text{for } \xi \leq -1, \\ 1 & \text{for } \xi \geq 1, \end{cases}
\]

with the property that

$$\rho(\xi)^2 + \rho(-\xi)^2 = 1 \quad \text{for all } \xi \in \mathbb{R}. \quad (4)$$

Define for each $I = [\alpha_I, \alpha'_I) \in \mathcal{I}$ the **bell function**

$$b_I(\xi) := \rho \left( \frac{\xi - \alpha_I}{\varepsilon_I} \right) \rho \left( \frac{\alpha'_I - \xi}{\varepsilon'_I} \right). \quad (5)$$

Notice that $\text{supp}(b_I) \subset [\alpha_I - \varepsilon_I, \alpha'_I + \varepsilon'_I]$ and $b_I(\xi) = 1$ for $\xi \in [\alpha_I + \varepsilon_I, \alpha'_I - \varepsilon'_I]$. Now the set of local cosine functions

$$\hat{w}_{n,I}(\xi) = \sqrt{\frac{2}{|I|}} b_I(\xi) \cos \left( \pi \left( n + \frac{1}{2} \right) \frac{\xi - \alpha_I}{|I|} \right), \quad n \in \mathbb{N}_0, \quad I \in \mathcal{I}, \quad (6)$$

with $\mathbb{N}_0 := \mathbb{N} \cup \{0\}$, constitute an orthonormal basis for $L_2(\mathbb{R})$, see e.g. [2]. We call the collection $\{w_{n,I}: I \in \mathcal{I}, n \in \mathbb{N}_0\}$ a **brushlet system**. The brushlets also have an explicit representation in the time domain. Define the set of **central bell functions** $\{g_I\}_{I \in \mathcal{I}}$ by

$$g_I(\xi) := \rho \left( \frac{|I|}{\varepsilon_I} \xi \right) \rho \left( \frac{|I|}{\varepsilon'_I} (1 - \xi) \right),$$

$$\hat{g}_I(\xi) = \sqrt{\frac{2}{|I|}} g_I(\xi) \cos \left( \pi \left( n + \frac{1}{2} \right) \frac{\xi - \alpha_I}{|I|} \right), \quad n \in \mathbb{N}_0, \quad I \in \mathcal{I}, \quad (7)$$
such that \( b_I(\xi) = \hat{g}_I(|I|^{-1}(\xi - \alpha_I)) \), and let for notational convenience 
\[ e_{n,I} := \frac{\pi(n + \frac{1}{2})}{|I|}, \quad I \in \mathbb{I}, \; n \in \mathbb{N}_0. \]

Then, 
\[ w_{n,I}(x) = \sqrt{\frac{|I|}{2}} e^{ia_I x} \{ g_I(|I|(x + e_{n,I})) + g_I(|I|(x - e_{n,I})) \}. \]  

(8)

By a straight forward calculation it can be verified (see [3]) that for \( r \geq 1 \) there exists a constant \( C := C(r) < \infty \), independent of \( I \in \mathbb{I} \), such that 
\[ |g_I(x)| \leq C(1 + |x|)^{-r}. \]  

(9)

Thus a brushlet \( w_{n,I} \) essentially consists of two well localized humps at the points \( \pm e_{n,I} \).

Given a bell function \( b_I \), define an operator \( \mathcal{P}_I : L_2(\mathbb{R}) \to L_2(\mathbb{R}) \) by 
\[ \widehat{\mathcal{P}_I f}(\xi) := b_I(\xi) [b_I(\xi) f(\xi) + b_I(2\alpha_I - \xi) \hat{f}(2\alpha_I - \xi) - b_I(2\alpha'_I - \xi) \hat{f}(2\alpha'_I - \xi)] \]  

(10)

It can be verified that \( \mathcal{P}_I \) is an orthogonal projection, mapping \( L_2(\mathbb{R}) \) onto \( \mathcal{R} \left\{ w_{n,I} : n \in \mathbb{N}_0 \right\} \). In Section 2.2, we will need some of the finer properties of the operator given by (10). Let us list properties here, and refer the reader to [13, Chap. 1] for a more detailed discussion of the properties of local trigonometric bases.

Suppose \( I = [\alpha_I, \alpha'_I] \) and \( J = [\alpha_J, \alpha'_J] \) are two adjacent compatible intervals (i.e., \( \alpha'_I = \alpha_J \) and \( \varepsilon'_I = \varepsilon_J \)). Then it holds true that 
\[ \mathcal{P}_I f(\xi) + \mathcal{P}_J f(\xi) = \hat{f}(\xi), \quad \xi \in [\alpha_I + \varepsilon_I, \alpha'_I - \varepsilon'_I], \quad f \in L_2(\mathbb{R}). \]  

(11)

We can verify (11) using the fact that \( b_I \equiv 1 \) on \([\alpha_I + \varepsilon_I, \alpha'_I - \varepsilon'_I]\) and that \( b_J \equiv 1 \) on \([\alpha_J + \varepsilon_J, \alpha'_J - \varepsilon'_J]\), together with the fact that 
\[ \text{supp}(b_I(\cdot) b_I(2\alpha_I - \cdot)) \subseteq [\alpha_I - \varepsilon_I, \alpha_I + \varepsilon_I] \]  

and 
\[ \text{supp}(b_I(\cdot) b_I(2\alpha'_I - \cdot)) \subseteq [\alpha'_I - \varepsilon'_I, \alpha'_I + \varepsilon'_I]. \]

For \( \xi \in [\alpha'_I - \varepsilon'_I, \alpha_J + \varepsilon_J] \) we notice that 
\[ \mathcal{P}_I f(\xi) + \mathcal{P}_J f(\xi) = [b_I^2(\xi) + b_J^2(\xi)] \hat{f}(\xi) \]  

\[ + \ v_J(\xi) b_J(2\alpha' - \xi) \hat{f}(2\alpha' - \xi) - b_I(\xi) b_J(2\alpha' - \xi) \hat{f}(2\alpha' - \xi). \]  

(12)

We can then conclude that (11) holds true using the following facts (see [13, Chap. 1])
\[ b_I(\xi) = b_J(2\alpha' - \xi), \quad b_J(\xi) = b_I(2\alpha - \xi), \quad \text{for} \ \xi \in [\alpha'_I - \varepsilon'_I, \alpha_J + \varepsilon_J], \]  

and 
\[ b_I^2(\xi) + b_J^2(\xi) = 1, \quad \text{for} \ \xi \in [\alpha_I + \varepsilon_I, \alpha'_I - \varepsilon'_I]. \]

Moreover,
\[ \mathcal{P}_I + \mathcal{P}_J = \mathcal{P}_{I \cup J} \]  

(13)

with the \( \varepsilon \)-values \( \varepsilon_I \) and \( \varepsilon'_J \) for \( I \cup J \).

Finally, for a rectangle \( Q = I \times J \subset \mathbb{R}^2 \) with \( I = [\alpha_I, \alpha'_I] \) and \( J = [\alpha_J, \alpha'_J] \), we define \( \mathcal{P}_Q = \mathcal{P}_I \otimes \mathcal{P}_J \). Clearly, \( \mathcal{P}_Q \) is a projection operator \( \mathcal{P}_Q : L_2(\mathbb{R}^2) \to \text{span}\{w_{i,I} \otimes w_{j,J} : i, j \in \mathbb{N}_0\} \).
Notice that,  
\[ P_Q = b_Q(D)\left[ (\Id + R_{\alpha_j} - R_{\alpha'_j}) \otimes (\Id + R_{\alpha_j} - R_{\alpha'_j}) \right] b_Q(D), \]  
where  
\[ b_Q(D)f := b_Q\hat{f}, \]  
with \( b_Q := b_f \otimes b_j \), and \( R_{\alpha}f(x) := e^{i2\alpha f(-x)}, x, a \in \mathbb{R} \). The corresponding orthonormal tensor product basis of brushlets is given by  
\[ w_{n,Q} := w_{n_1,I} \otimes w_{n_2,J}, \quad n = (n_1, n_2) \in \mathbb{N}_0^2. \]

2.2. Structured \( \alpha \)-coverings and bi-variate brushlet systems. We now turn to the task of creating bi-variate systems with a very specific time-frequency structure that turns out to be well-adapted for the analysis of homogeneous \( \alpha \)-modulation spaces. We are going to fix \( 0 \leq \alpha < 1 \). In this section, \( \alpha \) can be considered just a parameter that can be used to "tune" the specific time-frequency properties of the resulting bi-variate system. We first consider the following subsets of the real axis, with endpoints that are compatible with standard univariate \( \alpha \)-coverings, see [4],

\[ A_j := \left[ -j^{1-\alpha}, j^{1-\alpha} \right), \quad j = 1, 2, \ldots \]

For the low frequencies we will need the following subsets

\[ A_j := \left[ -|j|^{1-\alpha}, |j|^{1-\alpha} \right), \quad j = -1, -2, \ldots \]

We will need to create additional intervals for the final covering. For this we make a further subdivision of \( [-j^{1-\alpha}, j^{1-\alpha}] \) into \( 2|j|/r_1 + 1 \) intervals, where \( r_1 \) is chosen sufficiently small and such that \( 2|j|/r_1 = 2N_j \in 2\mathbb{N}. \) We write

\[ [-j^{1-\alpha}, j^{1-\alpha}] = I_{j,-N_j} \cup I_{j,-N_j+1} \cup \cdots \cup I_{j,N_j}, \]

where \( I_{j,n} := [r_{j,n}, r_{j,n+1}], j = -N_j, \ldots, N_j, \) and we impose the particular "endpoint"-choices \( r_{j,-N_j+1} = -(j-1)^{1-\alpha} \) and \( r_{j,N_j-1} = (j-1)^{1-\alpha}, \) i.e.,

\[ I_{j,-N_j} = [-j^{1-\alpha}, -(j-1)^{1-\alpha}] \quad \text{and} \quad I_{j,N_j} = [(j-1)^{1-\alpha}, j^{1-\alpha}]. \]  

(16)

This is done to ensure seamless "gluing" later on when we create bi-variate systems.

We now repeat the process for \( [-|j|^{1-\alpha}, |j|^{1-\alpha}] \), \( j \in \{-1, -2, \ldots\} \), and make a division into \( 2|j|/r_1 + 1 \) intervals. We write, for \( j \in \{-1, -2, \ldots\} \),

\[ [-|j|^{1-\alpha}, |j|^{1-\alpha}] = I_{j,-N_j} \cup I_{j,-N_j+1} \cup \cdots \cup I_{j,N_j}, \]

where \( I_{j,n} := [r_{j,n}, r_{j,n+1}], j = -N_j, \ldots, N_j, \) and we again impose particular "endpoint"-choices \( r_{j,-N_j+1} = (|j|+1)^{1-\alpha} \) and \( r_{j,N_j-1} = (|j|+1)^{1-\alpha}, \) i.e.,

\[ I_{j,-N_j} = [-|j|^{1-\alpha}, -(|j|+1)^{1-\alpha}] \quad \text{and} \quad I_{j,N_j} = [(|j|+1)^{-1-\alpha}, |j|^{1-\alpha}]. \]  

(17)

For each interval \( I = [r_{j,s}, r_{j,s+1}] \), we associate a corresponding brushlet system with left \( \varepsilon \)-value \( \frac{1}{100} |r_{j,s}|^{1-\alpha} \) and right \( \varepsilon \)-value \( \frac{1}{100} |r_{j,s+1}|^{1-\alpha} \). The scaling factor \( \frac{1}{100} \) has been chosen to ensure that (2) is satisfied.

We now consider the rectangular "annuli" given by

\[ A_j = A_j^L \cup A_j^R \cup A_j^T \cup A_j^B, \quad j \in \mathbb{Z}\backslash\{0\}, \]
with

\[ A_j^L = \{ I_{j,-N_j} \times I_{j,n} \}_{-N_j \leq n \leq N_j}, \quad A_j^R = \{ I_{j,N_j} \times I_{j,n} \}_{-N_j \leq n \leq N_j}, \]

and

\[ A_j^T = \{ I_{j,n} \times I_{j,N_j} \}_{-N_j < n < N_j}, \quad A_j^B = \{ I_{j,n} \times I_{j,-N_j} \}_{-N_j < n < N_j}. \]

For notational convenience, we put \( A_0 = \emptyset \). The following result confirms that one can build orthonormal bi-variate brushlet bases based on the covering of \( \mathbb{R}^2 \) given by the sets \( \{ A_j \} \).

**Proposition 2.2.** The system \( \{ w_{n,Q} : n \in \mathbb{N}_0^2, Q \in A_j, j \in \mathbb{Z} \} \) forms an orthonormal basis for \( L_2(\mathbb{R}^2) \).

**Proof.** We first consider orthonormality. Let \( S_j := \{ w_{n,Q} : Q \in A_j, n \in \mathbb{N}_0^2 \} \) and notice that the functions in \( S_m \) and \( S_n \) have disjoint frequency support for \(|m - n| > 1\) (except in the special case \( m = -1 \) and \( n = 1 \), which will be considered below). Also notice, using the separable structure of the bi-variate brushlet functions, that the particular compatible endpoint structure, see (16) and (17), imposed on the partitioning of the sets \( A_j \) ensures that \( S_m \) is orthogonal to \( S_{m+1} \) for \( m < -1 \) and \( m \geq 1 \), and using the compatibility at the frequency one, we see that \( S_{-1} \) is orthogonal to \( S_1 \). Within each \( S_j \), orthonormality follows directly from the separable structure of the bi-variate brushlet system and the orthogonality of the respective univariate brushlet systems.

We will now verify completeness of the system, where we first notice that for \( f \in L_2(\mathbb{R}^2) \),

\[ \sum_{Q \in A_j, j \in \mathbb{Z}} \hat{P}_Q f(\xi), \]

is well-defined and converges pointwise as the support of each term in the sum overlaps with at most eight other terms corresponding to adjacent rectangles. Next, we notice that by repeated use of (13), for \( j > 1 \),

\[ \sum_{Q \in A_j^L} P_Q = P_{I_{j,-N_j}} \otimes P_{A_j}, \quad \sum_{Q \in A_j^R} P_Q = P_{I_{j,N_j}} \otimes P_{A_j}, \]

\[ \sum_{Q \in A_j^T} P_Q = P_{A_{j-1}} \otimes P_{I_{j,N_j}}, \quad \sum_{Q \in A_j^B} P_Q = P_{A_{j-1}} \otimes P_{I_{j,-N_j}}, \]

So, in particular, again using (13),

\[ P_{A_{j-1} \times A_{j-1}} + \sum_{Q \in A_j^L \cup A_j^T} P_Q = P_{A_{j-1} \times A_j}. \]

Using a similar argument for \( A_j^L \cup A_j^R \), and collecting terms, we may conclude that

\[ P_{A_{j-1} \times A_{j-1}} + \sum_{Q \in A_j} P_Q = P_{A_j \times A_j}, \quad j > 1. \]

Using a parallel argument, we may conclude that

\[ P_{A_{j-1} \times A_{j-1}} + \sum_{Q \in A_j} P_Q = P_{A_j \times A_j}, \quad j \leq -1. \]
UNCONDITIONAL BASES FOR HOMOGENEOUS $\alpha$-MODULATION SPACES

Noting that $A_{-1} = A_1$, it follows that
\[
\sum_{-N \leq j \leq N} \sum_{Q \in A_j} P_Q = P_{A_N \times A_N} - P_{A_{-N-1} \times A_{-N-1}}.
\]

It thus follows easily that
\[
\lim_{N \to \infty} \sum_{-N \leq j \leq N} \sum_{Q \in A_j} P_Q = \text{Id}_{L_2(\mathbb{R}^2)},
\]
in the strong operator topology. This completes the proof. \(\square\)

Let us conclude this section by introducing some additional notation. Put
\[
Q^\alpha := \bigcup_{j \in \mathbb{Z}} A_j.
\]

For an arbitrary rectangle $Q = I \times J \in Q^\alpha$, we let $\xi_Q \in Q$ denote the mid-point of $Q$. Put $Q_0 := [-1/2, 1/2]^2$, and note that
\[
Q = \delta_Q(Q_0) + \xi_Q,
\]
where $\delta_Q := \text{diag}(|I|, |J|)$. This shows that $Q^\alpha$ is a so-called structured covering in the terminology of [1]. Notice also that the covering satisfies the geometric rule
\[
|Q| \asymp |\xi_Q|^{\beta(Q)}, \quad \beta(Q) = \begin{cases} 2\alpha, & Q \in \bigcup_{j>0} A_j; \\ 2(2-\alpha), & Q \in \bigcup_{j<0} A_j. \end{cases}
\]

3. HOMOGENEOUS $\alpha$-MODULATION SPACES

In this section we introduce $\alpha$-modulation and $\alpha$-TL spaces in the homogeneous setting, an extension that was first considered in [1]. In the inhomogeneous setup on the real line, an $\alpha$-covering can easily be obtained from the knots $\pm n^\beta$, $n \in \mathbb{N}$, taking $\beta = 1/(1-\alpha)$ for $0 \leq \alpha < 1$, while in the limiting (Besov) case $\alpha = 1$, we simply use dyadic knots $\pm 2^j$, $j \in \mathbb{N}$. Now, in the Besov case, we add the low frequency knots $\pm 2^{-j}$, $j \in \mathbb{N}$, to obtain a full decomposition yielding homogeneous Besov spaces. Notice that the low frequency knots can be considered the image under $\xi \to 1/\xi$ of the high frequency knots. The idea is now to copy this process for the $\alpha$-covering obtaining low-frequency knots $\pm n^{-\beta}$, $n \in \mathbb{N}$, that can be seen to satisfy the geometric “rule” $|n^{-\beta} - (n+1)^{-\beta}| \asymp n^{-\beta(2-\alpha)}$, while the high-frequency knots satisfy $|(n+1)^{-\beta} - n^{-\beta}| \asymp n^{\alpha\beta}$.

Inspired by these considerations, we define a general hybrid weight $\tilde{h}_\alpha : \mathbb{R}^2 \to \mathbb{R}_+$ by $\tilde{h}_\alpha(\xi) := \rho(\xi) h_1(\xi) + (1 - \rho(\xi)) h_2(\xi)$, where $\rho : \mathbb{R}^2 \to \mathbb{R}_+$ is a smooth function that satisfies
\[
\rho(x) := \begin{cases} 1, & |x| \leq \frac{2}{3}; \\ 0, & |x| \geq \frac{4}{3} ; \end{cases}
\]
$h_1(\xi) = |\xi|^{2-\alpha}$ and $h_2(\xi) = |\xi|^{\alpha}$.

We now introduce the notion of an $\alpha$-covering.
Definition 3.1. A countable set $Q$ of subsets $Q \subset \mathbb{R}^2 \setminus \{0\}$ is called an admissible covering if $\mathbb{R}^2 \setminus \{0\} = \bigcup_{Q \in Q} Q$ and there exists $n_0 < \infty$ such that

$$\#\{Q' \in Q : Q \cap Q' \neq \emptyset\} \leq n_0$$

for all $Q \in Q$. Let

$$r_Q = \sup\{r \in \mathbb{R}^+ : B(c_r, r) \subset Q \text{ for some } c_r \in \mathbb{R}^2\},$$

$$R_Q = \inf\{R \in \mathbb{R}^+ : Q \subset B(c_R, R) \text{ for some } c_R \in \mathbb{R}^2\}$$

denote, respectively, the radius of the inscribed and circumscribed disc of $Q \in Q$. An admissible covering is called a homogeneous $\alpha$-covering if $|Q|^{1/2} \propto \tilde{h}_\alpha(\xi)$ (uniformly) for all $x \in Q$ and for all $Q \in Q$, and there exists a constant $K \geq 1$ such that $R_Q / r_Q \leq K$ for all $Q \in Q$.

We have already noticed that the covering $Q^\alpha$ satisfies, for $Q \in Q^\alpha$,

$$|Q|^{1/2} \propto \tilde{h}_\alpha(\xi), \quad \text{(uniformly) for all } \xi \in Q. \quad (20)$$

It is also straightforward to verify that the inscribed/circumscribed disc condition is satisfied as the rectangles in $Q^\alpha$ have eccentricity close to one, so we may pick $r_Q \propto R_Q \approx |Q|^{1/2}$, uniformly in $Q \in Q^\alpha$. We conclude that $Q^\alpha$ is indeed a homogeneous $\alpha$-covering. It was proven in [1, Lemma 2.8] that the weight $\tilde{h}_\alpha$ is moderate relative to $Q^\alpha$ in the sense that there exists a constant $R > 0$ depending only on $Q^\alpha$ such that for $Q \in Q^\alpha$,

$$R^{-1} \leq \frac{\tilde{h}_\alpha(x)}{\tilde{h}_\alpha(y)} \leq R, \quad x, y \in Q.. \quad (21)$$

In order to define smoothness spaces adapted to $\alpha$-coverings, we need to consider an associated slightly expanded $\alpha$-covering defined by the sets

$$Q^\varepsilon := \delta_Q([-0.6, 0.6]^2) + \xi_Q, \quad Q \in Q^\alpha,$$

where $\xi_Q$ and $\delta_Q$ are defined in (18). The only important characteristic of the number 0.6 in this context is that it is slightly larger than 1/2. It is proven in [1, Proposition 2.5] that one can create two bounded partitions of unity (BAPUs) of smooth functions $\{\varphi_Q\}_{Q \in Q^\alpha}$ and $\{\tilde{\varphi}_Q\}_{Q \in Q^\alpha}$ satisfying $\text{supp}(\varphi_Q) \subseteq Q^\varepsilon$,

$$\sum_{Q \in Q^\alpha} \varphi_Q(\xi) = \sum_{Q \in Q^\alpha} \tilde{\varphi}_Q(\xi) = 1, \quad \xi \in \mathbb{R}^2 \setminus \{0\},$$

and $\tilde{\varphi}_Q(x) = 1$ for $x \in \text{supp}(\varphi_Q)$, $Q \in Q^\alpha$. Moreover, one can ensure that the sequences $\{\varphi_Q\}$ and $\{\tilde{\varphi}_Q\}$ act as bounded multiplier sequences on certain vector-valued $L_p$-spaces as stated in Proposition A.2. We will not discuss this rather technical issue here, but instead refer the reader to the discussion in [1,6], and henceforth assume that $\{\varphi_Q\}$ and $\{\tilde{\varphi}_Q\}$ both are constructed such that they satisfy the multiplier condition needed for Proposition A.2 for any $0 < p < \infty$ and $0 < q \leq \infty$.

We can now define the homogeneous (anisotropic) T-L type spaces and the decomposition spaces. We let $\mathcal{S} \setminus \mathcal{P}$ denote the class of tempered distributions modulo polynomials defined on $\mathbb{R}^2$.

Definition 3.2. Let $\tilde{h}_\alpha$ be a hybrid weight for $Q^\alpha$. Let $\{\varphi_j\}_{j \in J}$ be a corresponding BAPU and set $\varphi_j(D)f := F^{-1}(\varphi_j F f)$. 

• For $s \in \mathbb{R}, 0 < p < \infty$ and $0 < q \leq \infty$, we define the (anisotropic) homogeneous Triebel-Lizorkin space $\dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ as the set all $f \in \mathcal{S}' \setminus \mathcal{P}$ satisfying

$$\|f\|_{\dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2)} := \left\| \left( \sum_{Q \in \mathcal{Q}^\alpha} \left| \hat{h}_\alpha(\xi_Q) s\varphi_Q(D) f \right|^q \right)^{1/q} \right\|_{L^p} < \infty.$$ 

• For $s \in \mathbb{R}, 0 < p \leq \infty$ and $0 < q < \infty$ we define the (anisotropic) homogeneous decomposition space $\dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ as the set of all $f \in \mathcal{S}' \setminus \mathcal{P}$ satisfying

$$\|f\|_{\dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2)} = \left( \sum_{Q \in \mathcal{Q}^\alpha} \left| \hat{h}(\xi_Q) s\varphi_Q(D) f \right|^q \right)^{1/q} < \infty,$$

with the usual modification if $q = \infty$.

It can be verified that $\dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ and $\dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ are quasi-Banach spaces if $0 < p < 1$ or $0 < q < 1$, and they are Banach spaces when $1 \leq p, q < \infty$. The particular space does not (up to norm equivalence) depend on the choice of $\rho$ in the definition of $\hat{h}_\alpha$ nor does it depend on the particular choice of sample frequencies $\xi_Q$ as long as $\xi_Q \in Q$, see the moderation condition (21), and it does not depend on the particular choice of BAPU, see [1, 6]. In particular, $\{\varphi_Q\}_Q$ will generate the same spaces up to norm equivalence. We mention that it is possible to consider other reservoirs of distributions than $\mathcal{S}' \setminus \mathcal{P}$ to build the function spaces, see Voigtlaender [24] for further details.

Let us recall that class $\mathcal{S}_0 := \mathcal{S}_0(\mathbb{R}^2)$, which is the closed subspace of the Schwartz class $\mathcal{S}(\mathbb{R}^2)$, is defined by

$$\mathcal{S}_0 = \left\{ f \in \mathcal{S}(\mathbb{R}^2) : \int f(x) \cdot x^\alpha \, dx = 0 \text{ for all } \alpha \in \mathbb{N}^2_0 \right\}.$$

It can be proved that $\dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ and $\dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ satisfy

$$\mathcal{S}_0 \hookrightarrow \dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2) \hookrightarrow \mathcal{S}' \setminus \mathcal{P}, \quad \mathcal{S}_0 \hookrightarrow \dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2) \hookrightarrow \mathcal{S}' \setminus \mathcal{P},$$

see [1]. Moreover, if $p, q < \infty$, $\mathcal{S}_0$ is dense in $\dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2)$.

### 3.1. A characterization of $\dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2)$

We claim that the spaces $\dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ and $\dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ can be completely characterized using the brushlet system build on $Q^n$. In this note, we focus on proving this claim for the Triebel-Lizorkin type spaces $\dot{F}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ spaces. For the many of the proofs in this Section, we will call on results on vector-valued multiplies that can be found in Appendix A. The modulation spaces $\dot{M}^{s,\alpha}_{p,q}(\mathbb{R}^2)$ are easier to handle due to their (simpler) structure, and the reader can verify that the results and proofs presented in [18] can be adapted to this homogeneous setup.

For $Q = I \times J \in \cup_j \Lambda_j$, we defined an associated dilation matrix by $\delta_Q := \text{diag}(|I|, |J|)$. We define for $n \in \mathbb{N}^2_0$,

$$U(Q, n) = \left\{ y \in \mathbb{R}^2 : \delta_Q y - \pi(n + a) \in B(0, 1) \right\}, \quad (22)$$
where \( a := \left[ \frac{1}{2}, \frac{1}{2} \right]^T \). It is easy to verify there exists \( L < \infty \) so that uniformly in \( x \) and \( Q, \sum_{n} \chi_{U(Q,n)}(x) \leq L \). One may also verify that for \( n, n' \in \mathbb{N}_0 \), \( U(Q, n') = U(Q, n) + \pi \delta_Q^{-1}(n' - n) \).

We can now prove that the canonical coefficient operator is bounded on \( F_{p,q}^s(h, w) \).

**Lemma 3.3.** Let \( \{T_Q = \delta_Q \cdot \xi_Q\}_{Q \in \mathcal{Q}^a} \) be the family of invertible affine transformations associated with \( \mathcal{Q}^a \) in (18). Suppose \( s \in \mathbb{R}, 0 < p < \infty, \) and \( 0 < q \leq \infty \). Then

\[
\|S^s_q(f)\|_{L_p} \leq C\|f\|_{F_{p,q}^s}, \quad f \in \dot{F}_{p,q}^{s,\alpha}(\mathbb{R}^2),
\]

where

\[
S^s_q(f) := \left( \sum_{Q} \sum_{n \in \mathbb{N}_0^2} \left( \hat{h}_\alpha(\xi_Q)^s |\langle f, w_{n,Q} \rangle_A |Q|^{1/2} \chi_{U(Q,n)} \right)^q \right)^{1/p},
\]

with \( U(Q, n) \) given in (22).

**Remark 3.4.** Using the observation in (20), we also have

\[
S^s_q(f) \asymp \left( \sum_{Q} \sum_{n \in \mathbb{N}_0^2} \left( \hat{h}_\alpha(\xi_Q)^{s+1} |\langle \cdot, w_{n,Q} \rangle_A |Q|^{1/2} \right) \right)^{1/p}.
\]

**Proof.** Take \( f \in F_{p,q}^{s,\alpha}(\mathbb{R}^2) \) and fix \( Q \in \mathcal{Q}^a \). We write the cosine term in Eq. (6) as a sum of complex exponentials, and we take a tensor product to create \( w_{n,Q} \). This process creates a bi-variate function with four “humps”, and, as it turns out, we will consequently need four terms to control the inner product \( \langle f, w_{n,Q} \rangle \). We first obtain the estimate

\[
|\langle f, w_{n,Q} \rangle| \leq \sqrt{\frac{2}{|Q|}} \sum_{j=1}^4 \left| (b_Q(D)f)(v_j) \right|,
\]

with \( b_Q(D) \) defined in (15), \( v_1 := \pi \delta_Q^{-1}(n + a), v_2 := -v_1, v_3 := \hat{v}_1, v_4 := \hat{v}_2, \) where for a vector \( v = [v_1, v_2]^T, \) we let \( \hat{v} := [v_1, -v_2]^T \). Notice, if \( U(Q, n) \cap U(Q, n') \neq \emptyset \) and \( u \in U(Q, n), v \in U(Q, n') \) then \( |u - v| \leq c|Q|^{-1/2} \) for some \( c > 0 \) independent of \( Q \). Using the observations about the sets \( U(Q, n) \) above, and defining the linear maps \( R_j : \mathbb{R}^2 \rightarrow \mathbb{R}^2, j = 1, \ldots, 4, \) by \( R_1 := \text{Id}, R_2 := -R_1, R_3u := \tilde{u}, u \in \mathbb{R}^2, \) and \( R_4 := -R_3, \) we obtain

\[
|\langle b_Q(D)(f)(v_1) \rangle| \leq \sup_{y \in U(Q,n)} |\langle b_Q(D)(f)(y) \rangle| \leq \sup_{u \in B(0, c|Q|^{-1/2})} |\langle b_Q(D)(f)(R_1x - u) \rangle|,
\]

\[
|\langle b_Q(D)(f)(v_2) \rangle| \leq \sup_{y \in U(Q,n-2a)} |\langle b_Q(D)(f)(y) \rangle| \leq \sup_{u \in B(0, c|Q|^{-1/2})} |\langle b_Q(D)(f)(R_2x - u) \rangle|,
\]

\[
|\langle b_Q(D)(f)(v_3) \rangle| \leq \sup_{y \in U(Q,\tilde{h}+e_1)} |\langle b_Q(D)(f)(y) \rangle| \leq \sup_{u \in B(0, c|Q|^{-1/2})} |\langle b_Q(D)(f)(R_3x - u) \rangle|,
\]

\[
|\langle b_Q(D)(f)(v_4) \rangle| \leq \sup_{y \in U(Q,-\tilde{h}-e_1)} |\langle b_Q(D)(f)(y) \rangle| \leq \sup_{u \in B(0, c|Q|^{-1/2})} |\langle b_Q(D)(f)(R_4x - u) \rangle|.
\]

We now estimate the inner sum in \( S^s_q(f) \) to obtain,

\[
\sum_{n \in \mathbb{N}_0^2} \langle f, w_{n,Q} \rangle |Q|^{1/2} \chi_{U(Q,n)}(x)^q
\]
Recall that $\text{supp}(b_{Q}(D)f) \subset T_{Q}([-0.6,0.6)^{2})$, so by Proposition A.1, Proposition A.2, and the estimate above,

$$\|S_{q}^{s}(f)\|_{L_{p}} \leq C\left\|\left(\sum_{Q} \langle \tilde{h}_{\alpha}(\xi_{Q})^{sq} \sum_{j=1}^{4} (b_{Q}(D)f)^{*}(2/r, c|Q|^{1/2}; R_{j}x))^{q}\right)^{1/p}\right\|_{L_{p}}$$

$$\leq C'\sum_{j=1}^{4} \left\|\left(\sum_{Q} \langle \tilde{h}_{\alpha}(\xi_{Q})^{sq}(b_{Q}(D)f)^{*}(2/r, c|Q|^{1/2}; R_{j}x))^{q}\right)^{1/p}\right\|_{L_{p}}$$

$$\leq 4C'\left\|\left(\sum_{Q} \langle \tilde{h}_{\alpha}(\xi_{Q})^{sq}(b_{Q}(D)f)^{*}(2/r, c|Q|^{1/2}; x))^{q}\right)^{1/p}\right\|_{L_{p}}$$

$$= 4C'\left\|\left(\sum_{Q} \langle \tilde{h}_{\alpha}(\xi_{Q})^{sq}(\tilde{\varphi}_{Q}(D)f)^{x}(2/r, c|Q|^{1/2}; x))^{q}\right)^{1/p}\right\|_{L_{p}}$$

$$\leq C''\left\|\left(\sum_{Q} \langle \tilde{h}_{\alpha}(\xi_{Q})^{sq}(\tilde{\varphi}_{Q}(D)f)(x))^{q}\right)^{1/p}\right\|_{L_{p}}$$

$$= C''\|f\|_{F_{p,q}^{s,q}}.$$

Inspired by Lemma 3.3, we define the sequence space $\dot{f}_{p,q}^{s,q}(\mathbb{R}^{2}) := \dot{f}_{p,q}^{s,q}(\mathbb{R}^{2})$ for $s \in \mathbb{R}$, $0 < p < \infty$, and $0 < q \leq \infty$, as the set of sequences $\{s_{Q,n}\}_{Q \in \mathbb{Q}, n \in \mathbb{Z}^{d}} \subset \mathbb{C}$ satisfying

$$\|\{s_{Q,n}\}\|_{F_{p,q}^{s,q}} := \left\|\left\{\hat{h}_{\alpha}(\xi_{Q})^{s}|Q|^{1/2}\left(\sum_{n \in \mathbb{Z}^{d}} |s_{Q,n}|^{q} \chi_{U(Q,n)}\right)^{1/q}\right\}\right\|_{L_{p}(\ell_{q})} < \infty,$$

where the $L_{p}(\ell_{q})$-norm is defined for a sequence $f = \{f_{j}\}_{j \in \mathbb{N}}$ of measurable functions by

$$\|f\|_{L_{p}(\ell_{q})} := \left\|\left(\sum_{j \in \mathbb{N}} |f_{j}|^{q}\right)^{1/q}\right\|_{L_{p}(\mathbb{R}^{2})},$$

see also Appendix A. Lemma 3.3 provides us with a bounded coefficient operator $C: F_{p,q}^{s,q} \rightarrow \dot{f}_{p,q}^{s,q}$ given by

$$Cf = \{(f, w_{n,Q})\}_{Q \in \mathbb{Q}, n \in \mathbb{N}_{0}^{d}}.$$ (24)
Moreover, the fact that \( \{w_{n,Q} \} \) is an orthonormal basis shows that the only consistent definition of a reconstruction operator is given by

\[
R : \{s_{Q,n}\}_{Q,n} \rightarrow \sum_{Q,n} s_{Q,n} w_{n,Q}.
\] (25)

Using Lemma A.3 we now verify that \( R : f_{p,q}^{s,\alpha} \rightarrow F_{p,q}^{s,\alpha} \) is also a bounded operator.

**Lemma 3.5.** Suppose \( 0 \leq \alpha < 1 \), \( s \in \mathbb{R} \), \( 0 < p < \infty \), and \( 0 < q \leq \infty \). Then for any finite sequence \( \{s_{Q,n}\}_{Q,n} \), we have

\[
\left\| \sum_{Q,n} s_{Q,n} w_{n,Q} \right\|_{F_{p,q}^{s,\alpha}} \leq C \left\| \{s_{Q,n}\} \right\|_{F_{p,q}^{s,\alpha}}.
\]

**Proof.** Let \( \{\varphi_Q\}_{Q \in Q} \) be the BAPU associated with \( Q' \). Using the structure given by (6), and Proposition A.2, we get

\[
\left\| \sum_{Q,n} s_{Q,n} w_{n,Q} \right\|_{F_{p,q}^{s,\alpha}} = \left\| \left\{ w(\xi_Q)^s \varphi_Q(D) \left( \sum_{Q',n} s_{Q',n} w_{Q',n} \right) \right\}_Q \right\|_{L_p(\ell_q)} \leq C \left\| \left\{ \tilde{h}_n(\xi_Q)^s \sum_{Q' \in N(Q)} \sum_n s_{Q',n} w_{Q',n} \right\}_Q \right\|_{L_p(\ell_q)},
\]

where \( N(Q) = \{Q' \in Q : \text{supp}(\varphi_Q) \cap \text{supp}(h_{cQ'}) \neq \emptyset \} \). It follows from [1, Lemma 2.8] that \#\( N(Q) \) is uniformly bounded, and since \( \tilde{h}_n \) is a moderate weight, see (21), we obtain

\[
\left\| \left\{ \tilde{h}_n(\xi_Q)^s \sum_{Q' \in N(Q)} \sum_n s_{Q',n} w_{Q',n} \right\}_Q \right\|_{L_p(\ell_q)} \leq C \left\| \left( \sum_{Q'} \left( w(\xi_Q)^s \sum_n |s_{Q',n}| w_{Q',n} \right)^q \right)^{1/q} \right\|_{L_p}.
\]

Fix \( 0 < r < \min(1,p,q) \). Then Lemma A.3 and the Fefferman-Stein maximal inequality (26) yields

\[
\left\| \left\{ \tilde{h}_n(\xi_Q)^s \sum_n |s_{Q,n}| \eta_{Q,n} \right\}_Q \right\|_{L_p(\ell_q)} \leq C \left\| \left\{ \tilde{h}_n(\xi_Q)^s \right\}^{1/2} \sum_{\ell=1}^4 M_\ell \left( \sum_n |s_{Q,n}| \chi U(Q,n) \right) \right\|_{L_p(\ell_q)} \leq C \left\{ \tilde{h}_n(\xi_Q)^s \right\} \sum_n |s_{Q,n}| \chi U(Q,n),
\]

where we used the (quasi-)triangle inequality and straightforward substitutions in the integrals. The result now follows since the sum over \( n \) is locally finite with a uniform bound on the number of non-zero terms, which implies that

\[
\left( \sum_n |s_{k,n}| \chi U(Q,n) \right)^q \leq \sum_n |s_{Q,n}|^q \chi U(Q,n),
\]

uniformly in \( Q \).

We now use Lemma 3.3 and Lemma 3.5 to obtain the main result of this paper, that \( \{w_{n,Q}\} \) forms captures the norm of \( \hat{F}_{p,q}^{s,\alpha} \), and forms an unconditional basis for \( \hat{F}_{p,q}^{s,\alpha} \) in the Banach space case.
Theorem 3.6. Let \( s \in \mathbb{R}, 0 < p, q < \infty \). Then we have the norm characterization
\[
\|f\|_{\dot{F}_{p}^{s, \alpha}} \asymp \|S_{q}^{s}(f)\|_{L_{p}},
\]
with \( S_{q}^{s}(f) \) given by (23). Moreover, for \( 1 \leq p, q < \infty \), \( \{w_{n,Q}\} \) forms an unconditional basis for \( S_{q}^{s}(\cdot) \).

Proof. The norm characterization follows at once by combining Lemma 3.3 and Lemma 3.5. The claim that the system forms an unconditional basis when \( 1 \leq p, q < \infty \) follows easily from the fact that \( \dot{F}_{p}^{s, \alpha} \) is a Banach space, and that finite expansions in \( \{w_{n,Q}\} \) have uniquely determined coefficients giving us a norm characterization of such expansions using the \( L_{p}\)-norm of \( S_{q}^{s}(\cdot) \).

We conclude with a few remarks on Theorem 3.6.

a. A result similar to Theorem 3.6, but with a much simplified proof, holds true for the homogeneous \( \alpha \)-modulation spaces \( \dot{M}_{p,q}^{s, \alpha}(\mathbb{R}^{2}) \). For this case, one can follow the approach in [1, 18].

b. The norm characterisation obtained in Theorem 3.6 may appear similar to the characterisation obtained for tight frames in [1, Theorem 7.5], but one should notice the important additional fact that \( \{w_{n,Q}\} \) forms an unconditional basis. This fact has significant implications for, e.g., \( n \)-term nonlinear approximation from \( \{w_{n,Q}\} \), where the linear independence will allow one to prove inverse estimates of Bernstein type. Inverse estimates are currently out of reach for the redundant frames considered in [1], see the discussion of this problem in [20]. Approximation properties of \( \{w_{n,Q}\} \) will be considered in a future publication.

APPENDIX A. SOME TECHNICAL RESULTS

This appendix contains some results on vector-valued maximal functions needed for the analysis of the \( \alpha \)-TL spaces.

For \( 0 < r < \infty \), the Hardy-Littlewood maximal function is defined by
\[
M_{r}u(x) := \sup_{t>0} \left( \frac{1}{|B(x,t)|} \int_{B(x,t)} |u(y)|^{r} \, dy \right)^{1/r}, \quad u \in L_{r,\text{loc}}(\mathbb{R}^{2}).
\]

For \( 0 < p, q \leq \infty \), and a sequence \( f = \{f_{j}\}_{j \in \mathbb{N}} \) of \( L_{p}(\mathbb{R}^{2}) \) functions, we define the norm
\[
\|f\|_{L_{p}(\ell_{q})} := \left\| \left( \sum_{j \in \mathbb{N}} |f_{j}|^{q} \right)^{1/q} \right\|_{L_{p}(\mathbb{R}^{2})}.
\]

Where there is no risk of ambiguity we will abuse notation and write \( \|f_{k}\|_{L_{p}(\ell_{q})} \) instead of \( \|\{f_{k}\}_{k}\|_{L_{p}(\ell_{q})} \).

The vector-valued Fefferman-Stein maximal inequality gives the estimate (see [22, Chapters I&II])
\[
\|\{M_{r}f_{j}\}\|_{L_{p}(\ell_{q})} \leq C_{B}\|\{f_{j}\}\|_{L_{p}(\ell_{q})}
\]
for \( r < q \leq \infty \) and \( r < p < \infty \), \( C_{B} := C_{B}(r, p, q) \).

For \( \Omega = \{\Omega_{n}\} \) a sequence of compact subsets of \( \mathbb{R}^{2} \), we let
\[
L_{p}^{\Omega}(\ell_{q}) := \{f_{n}\}_{n \in \mathbb{N}} \in L_{p}(\ell_{q}) \mid \text{supp}(\hat{f}_{n}) \subseteq \Omega_{n}, \forall n \}.
\]
For $\xi \in \mathbb{R}^2$, we let $\langle \xi \rangle := (1 + |\xi|^2)^{1/2}$. Let $u(x)$ be a continuous function on $\mathbb{R}^2$. We define, for $a, R > 0$,

$$u^*(a, R; x) := \sup_{y \in \mathbb{R}^2} \langle y \rangle^{-a}|u(x - y/R)|, \quad x \in \mathbb{R}^2.$$ 

The following is a variation on Peetre’s maximal estimate in a vector-valued setting.

**Proposition A.1.** Suppose $0 < p < \infty$ and $0 < q \leq \infty$, and let $\Omega = \{T_k C\}_{k \in \mathbb{N}}$ be a sequence of compact subsets of $\mathbb{R}^2$ generated by a family $\{T_k = t_k I_d \cdot + \xi_k\}_{k \in \mathbb{N}}$ of invertible affine transformations on $\mathbb{R}^2$, with $C$ a fixed compact subset of $\mathbb{R}^2$. If $0 < r < \min(p, q)$, then there exists a constant $K$ such that

$$\left\| \{(f_k)^*(2/r, t_k; \cdot)\} \right\|_{L_p(\ell_q)} \leq K \|\{f_k\}\|_{L_p(\ell_q)},$$  

(27)

for all $f \in L_p^\Omega(\ell_q)$, where $f = \{f_k\}_{k \in \mathbb{N}}$.

Finally, we need the following vector-valued multiplier result. For $s \in \mathbb{R}_+$, we let

$$\|f\|_{H^s_2} := \left( \int |\mathcal{F}^{-1} f(x)|^2 \langle x \rangle^{2s} dx \right)^{1/2}$$

denote the Sobolev norm.

**Proposition A.2.** Suppose $0 < p < \infty$ and $0 < q \leq \infty$, and let $\Omega = \{T_k C\}_{k \in \mathbb{N}}$ be a sequence of compact subsets of $\mathbb{R}^2$ generated by a family $\{T_k = t_k I_d \cdot + \xi_k\}_{k \in \mathbb{N}}$ of invertible affine transformations on $\mathbb{R}^2$, with $C$ a fixed compact subset of $\mathbb{R}^2$. Assume $\{\psi_j\}_{j \in \mathbb{N}}$ is a sequence of functions satisfying $\psi_j \in H^s_2$ for some $s > \frac{\nu}{2} + \frac{\nu}{\min(p, q)}$. Then there exists a constant $C < \infty$ such that

$$\|\{\psi_k(D) f_k\}\|_{L_p(\ell_q)} \leq C \sup_j \|\psi_j(T_j \cdot)\|_{H^s_2} \cdot \|\{f_k\}\|_{L_p(\ell_q)}$$

for all $\{f_k\}_{k \in \mathbb{N}} \subset L_p^\Omega(\ell_q)$.

The following Lemma was used in the proof of Lemma 3.5.

**Lemma A.3.** Let $0 < r \leq 1$. There exists a constant $C$ such that for any sequence $\{s_{Q,n}\}_{Q,n}$ we have

$$\sum_n |s_{Q,n}| w_{n,Q}(x) \leq C |Q|^{1/2} \sum_{\ell=1}^4 M_{\ell} \left( \sum_n |s_{Q,n}| \chi_{U(Q,n)} \right)(R_{\ell}x).$$

**Proof.** From (9) we have that

$$|w_{n,Q}(x)| \leq C_N |Q|^{1/2} \sum_{\ell=1}^4 (1 + |R_{\ell}\delta_Qx - \pi(n + a)|)^{-N},$$  

(28)

for any $N > 0$, with $C_N$ independent of $Q$, where we use the same notation as in the proof of Lemma 3.5. Fix $N > 2/r$. We can, without loss of generality, suppose
\(x \in U(Q, 0)\). For \(j \in \mathbb{N}\), we let \(A_j = \{n \in \mathbb{N}^2_0 : 2^{j-1} < |\pi(n + a)| \leq 2^j\}\). Notice that \(U_n \in A_j U(Q, n)\) is a bounded set contained in the ball \(B(0, c2^{j+1}|Q|^{-1/2})\). Now,

\[
\sum_{n \in A_j} |s_{Q,n}| \left(1 + |\delta_Q x - \pi(n + a)|\right)^{-N} \leq C 2^{-jN} \sum_{n \in A_j} |s_{Q,n}| \\
\leq C 2^{-jN} \left(\sum_{n \in A_j} |s_{Q,n}|^r\right)^{1/r} \\
\leq C 2^{-jN}|Q|^{1/r} \left(\int \sum_{n \in A_j} |s_{Q,n}|^r \chi_{U(Q,n)}(y) \, dy\right)^{1/r} \\
\leq CL^{1-r}2^{-jN}|Q|^{1/r} \left(\int_{B(0,c2^{j+1}|Q|^{-1/2})} \left(\sum_{n \in A_j} |s_{Q,n}| \chi_{U(Q,n)}(y)\right)^r \, dy\right)^{1/r} \\
\leq C'2^{-j(N-2/r)} M_r \left(\sum_{n \in \mathbb{N}^2_0} |s_{Q,n}| \chi_{U(Q,n)}\right)(x).
\]

We now perform the summation over \(j \in \mathbb{N}_0\) to obtain

\[
\sum_{n \in \mathbb{N}^2_0} |s_{Q,n}| \left(1 + |\delta_Q x - \pi(n + a)|\right)^{-N} \leq CM_r \left(\sum_{n \in \mathbb{N}^2_0} |s_{Q,n}| \chi_{U(Q,n)}\right)(x).
\]

We then use the substitutions \(x = R\ell z, \ell = 1, \ldots, 4\), to cover all four terms on the RHS of (28), where we use the fact that \(R_\ell\) and \(\delta_Q\) commute. \(\square\)
