Abstract

The inclusive hadroproduction of a Higgs boson and of a jet, featuring large transverse momenta and well separated in rapidity, is proposed as a novel probe channel for the manifestation of the Balitsky-Fadin-Kuraev-Lipatov (BFKL) dynamics. Using the standard BFKL approach, with partial inclusion of next-to-leading order effects, predictions are presented for azimuthal Higgs-jet correlations and other observables, to be possibly compared with experimental analyses at the LHC and with theoretical predictions obtained in different schemes.

1 Introduction

The Balitsky-Fadin-Kuraev-Lipatov (BFKL) [1] approach is a consistent framework for the theoretical study in perturbative QCD of semi-hard processes [2], where the scale hierarchy, \( s \gg Q^2 \gg \Lambda_{\text{QCD}}^2 \), holds, \( s \) being the squared center-of-mass energy, \( Q \) the hard scale given by the process kinematics and \( \Lambda_{\text{QCD}} \) the QCD mass scale. For these processes, large energy logarithms enter the perturbative series with a power increasing with the perturbative order and compensate thereby the smallness of the strong coupling, \( \alpha_s \), thus calling for an all-order resummation. Within the BFKL approach, such a resummation is now amenable both in leading (LLA) and next-to-leading (NLA) approximations, and some steps towards the extension of the formalism beyond the NLA have also been done (see, e.g. Ref. [3]).

In the BFKL framework, the cross section of hadronic processes takes a peculiar factorized form, combining two impact factors, related to the transition from each colliding particle to the final-state object produced in the respective fragmentation region, and a process-independent Green’s function. The latter is determined by an integral equation, whose kernel is known at the next-to-leading order (NLO) both for forward scattering (i.e. for \( t = 0 \) and color singlet in the in the \( t \)-channel) [4, 5] and for any fixed, not growing with \( s \), momentum transfer \( t \) and any possible two-gluon color state in the \( t \)-channel [6–8]. Unfortunately, the list of impact factors known in the NLO is very short: 1) colliding-parton (quarks and gluons) impact factors [9–12], which represent the common basis for the calculation of the 2) forward-jet impact factor [13–17] and of the 3) forward light-charged hadron one [18], 4) the impact factor describing the \( \gamma^* \) to light-vector-meson leading twist transition [19], and 5) the \( \gamma^* \) to \( \gamma^* \) transition [20, 21]. This limits considerably the number of reactions which can be studied fully in the NLA BFKL approach.

To enlarge this number, one has to resort to partial inclusion of NLA effects, by taking the two impact factors, or just one of them, in the leading-order (LO), using though the NLA BFKL Green’s function.

Putting together full and partial NLA analyses, a respectable number of semi-hard reactions have been studied so far (see Ref. [22] for a review): the diffractive leptoproduction of two light vector mesons [23–26], the total cross section of two highly-virtual photons [27], the inclusive hadroproduction of two jets featuring large transverse momenta and well separated in rapidity (Mueller-Navelet channel [28]), for which several phenomenological studies have appeared so far [29–44], the inclusive detection of two light-charged hadrons [45–47], three- and four-jet hadroproduction [48–56], \( J/\Psi \)-jet [57], hadron-jet [58–60], Drell-Yan–jet [61, 62] and heavy-quark pair photo- [63, 64] and hadroproduction [65].

Another engaging direction is represented by the possibility of probing the proton structure at low-\( x \) through the BFKL resummation. More in particular, the emission of a single forward particle in lepton-proton or proton-proton scatterings offers us the chance to define an un integrated gluon distribution (UGD) in the proton, written as a suitable convolution of the BFKL gluon Green’s function and of a non-perturbative proton impact
factor. Formerly used for the investigation of DIS structure functions [66], the UGD has
later been studied via the exclusive diffractive electroproduction of a single light vector
meson [67–72] at HERA and via the forward inclusive Drell-Yan production [73–75] at
LHCb. Then, determinations of *collinear parton distribution functions* (PDFs) at NLO
and next-to-NLO (NNLO) fixed-order calculations, improved via the inclusion of NLA
small-\(x\) effects, were proposed in the last years [76–78]. Quite recently, a model calculation
of unpolarized and polarized *transverse-momentum-dependent* (TMD) gluon distributions
effectively encoding a BFKL-driven input on small-\(x\) tails was performed [79].

In this work we introduce and study with NLA BFKL accuracy a novel semi-hard
reaction, *i.e.* the concurrent inclusive production of a Higgs boson and a jet:

\[
\text{proton}(p_1) + \text{proton}(p_2) \rightarrow H(\vec{p}_H, y_H) + X + \text{jet}(\vec{p}_J, y_J),
\]

emitted with large transverse momenta, \(\vec{p}_{H,J} \gg \Lambda_{\text{QCD}}\), and separated by a large rapidity
gap, \(\Delta Y = y_H - y_J\). In Fig. 1 we present a pictorial view of this process, in the case when
the tagged object in the forward (backward) rapidity region is the Higgs boson (jet).

For a Higgs boson with mass \(M_H = 125.18\) GeV, the longitudinal-momentum fraction
of the parent proton carried by the struck gluon is rather small, down to \(x \sim 10^{-4} \div 10^{-3}\),
making it possible to give a description at the hand of the BFKL resummation. Recently,
a systematic framework to implement both the BFKL and the Sudakov resummations
for the Higgs boson plus jet production [80], based on the TMD factorization, has been
developed. The dominant partonic subprocess for the inclusive Higgs production at the
LHC is represented by the gluon-gluon fusion, \(gg \rightarrow H\), where the Higgs couples to gluons
via a (top) quark loop, with coupling proportional to the (top) quark mass \(M_t\). In our
proposal, following Ref. [81], we adopt a kinematics which strictly respects the semi-
hard regime, with the hard-scale set by the Higgs and top-quark masses, and the Higgs
and jet transverse momenta satisfying the condition, \(p_{H,J}^2 \sim M_H^2\). Moreover, to avoid
the appearance of Sudakov double logarithms (see, *e.g.*, Ref. [82]), unraveling only the
high-energy ones, we introduce suitable cuts on transverse momenta to prevent the back-
to-back emission of the Higgs and the jet, or to make this kinematical region marginal
with respect to the remaining phase space. The tag of a jet in the peripheral regions of
the detectors insures the existence of a large rapidity interval, \(\Delta Y = y_H - y_J \simeq \ln(s/Q^2)\),
with \(Q^2\) a typical hard-scale value.

The key ingredient, needed for the study of our process in the BFKL approach, is the
impact factor portraying the transition from a parton to a final-state Higgs boson, in the
scattering off a Reggeized gluon. At the LO, the initial-state parton can only be a gluon.

We will give predictions for cross section and correlations between the azimuthal angles
of the Higgs and the jet in a theoretical setup where NLA BFKL effects are included at
the level of the Green’s function.

The motivation for this work is twofold: on the phenomenological side, we want to
calculate the cross section and to study the angular distributions of the process \(1\) at LHC
energies. Note that for that case the final-state objects to be identified are within current experimental reach of the LHC; in particular, the detection of the Higgs can profit by the well tried tools developed for its discovery. On the theoretical side, our approach is in a sense complementary to the most common ones devoted to Higgs production, where high-energy (or small-$x$) effects are possibly included as an improvement with respect to fixed-order calculations in collinear-factorization (see, e.g., Refs [83, 84] where the Altarelli-Ball-Forte (ABF) small-$x$ resummation formalism is adopted [85]). Here, the view is reversed: we consider just high-energy effects, in the kinematical range where they only matter. Our results, which are the first for this kind of process encoding NLA BFKL effects, can therefore be used as a term of comparison for the other approaches, and contribute thereby to an improvement of our understanding of strong interactions. Moreover, the notorious problem of the NLA BFKL corrections, \textit{i.e.} that they are large and opposite in sign with respect to the LLA, should not affect severely the determination of azimuthal correlations\footnote{For ratios of azimuthal correlations it was shown that NLO effects are generally milder [86, 87].}, due to the large energy scale provided by the Higgs mass.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1}
\caption{Schematic representation of the inclusive Higgs-jet hadroproduction.}
\end{figure}
The main theoretical limitation of the present work is that the impact factor for the Higgs production is taken at the LO, although, as explained later, some NLO terms predictable on the basis of renormalization group analysis, have been included in our calculation. This may seem reductive, especially in consideration that Higgs-plus-jet production was already calculated in QCD at the NLO [88, 89] and even in NNLO QCD [90–93] through the Higgs effective field theory (HEFT) [94]. We believe that this limitation does not spoil the global picture, since in the high-energy limit the NLA effects in the BFKL Green’s function dominate over those in the impact factors. Nonetheless, the inclusion of NLO corrections to the Higgs impact factor is doable, though not trivial, and could be considered in future publications.

The paper is organized as follows: Section 2 is to set the theoretical framework up; Section 3 is devoted to our results for cross sections and azimuthal-angle correlations as a function of the rapidity interval, $\Delta Y$, between the tagged final objects (the Higgs boson and the jet); Section 4 carries our closing statements and some outlook.

## 2 Theoretical framework

For the process under consideration (see Fig. 1) we plan to construct the cross section, differential in some of the kinematic variables of the Higgs and the jet, and some azimuthal correlations between them. In the BFKL approach the cross section takes the factorized form, diagrammatically represented in Fig. 2, given by the convolution of the Higgs and jet impact factors with the BFKL gluon Green’s function, $G$.

### 2.1 Forward-Higgs LO impact factor

We can define the LO impact factor for the production of the Higgs in the gluon-gluon fusion channel, as follows (see, e.g., Ref. [95]):

$$V_{g\to H}^{(0)}(\vec{q}) = \sum_{\{f\}} \int \frac{ds_R}{2\pi} d(\text{PS})^{(f)} |\mathcal{M}|^2,$$

(2)

where $\mathcal{M}$ is the amplitude for the scattering of a gluon $g$, emitted by the colliding proton, off a Reggeon $R$ to produce a final state $f$, which at the LO, can only consist in a Higgs particle (see Fig. 3 for a representation of $|\mathcal{M}|^2$). The integration over the phase space $d(\text{PS})^{(f)}$ then simply gives

$$\text{PS}^{(4)} = \int \frac{d^4p_H}{(2\pi)^4} (2\pi)^4\delta(p_H^2 - M_H^2)(2\pi)^4\delta^{(4)}(k + q - p_H) = (2\pi)^4\delta(s_{sR} - M_H^2),$$

(3)

where $p_H$ is the Higgs boson momentum. Using this result, we end up with

$$V_{g\to H}^{(0)}(\vec{q}) = \frac{\alpha_s^2}{v^2} \frac{\vec{q}^2 |\mathcal{F}(\vec{q}^2)|^2}{128\pi^2 \sqrt{N_c^2 - 1}},$$

(4)
Figure 2: Schematic representation of the BFKL factorization for the Higgs-jet hadroproduction.

with $V^{(0)}_{g\to H}(q)|_{q=0} \to 0$, so that the infra-red finiteness of the BFKL amplitude is preserved. Here $v$ is the electroweak vacuum expectation value parameter, $v^2 = 1/(G_F\sqrt{2})$, and

$$
\mathcal{F}(\vec{q}^2) = 4 \int_0^1 dy \int_0^{1-y} dx \frac{1 - 4xy}{1 - \left(\frac{M_{H,t}}{M_t^2}\right) xy + \left(\frac{q^2}{M_t^2}\right) y(1-y)}.
$$

In this way we confirm, up to an irrelevant sign for $\mathcal{F}(\vec{q}^2)$, the results obtained earlier in Ref. [96]:

$$
\mathcal{F}(\vec{q}^2) = -\frac{4M_t^2}{M_{H,t}^2} \left\{-2 - \left(\frac{2\vec{q}^2}{M_{H,t}^2}\right) \left[\sqrt{z_1} \mathcal{W}(z_1) - \sqrt{z_2} \mathcal{W}(z_2)\right]\right. \\
+ \frac{1}{2} \left(1 - \frac{4M_t^2}{M_{H,t}^2}\right) \left[\mathcal{W}(z_1)^2 - \mathcal{W}(z_2)^2\right]\left\},
$$

with $\vec{q}$ the transverse component of the four-vector $q$, $M_{H,t} = \sqrt{M_H^2 + |\vec{q}|^2}$ the Higgs-boson transverse mass, $z_1 = 1 - 4M_t^2/M_H^2$, $z_2 = 1 + 4M_t^2/\vec{q}^2$, and the root $\sqrt{z_1} = i\sqrt{|z_1|}$.
is taken for negative values of $z_1$. Furthermore, we have

$$\mathcal{W}(z) = \begin{cases} -2i \arcsin \frac{1}{\sqrt{1-z}}, & z < 0; \\ \ln \frac{1 + \sqrt{z}}{1 - \sqrt{z}} - i\pi, & 0 < z < 1; \\ \ln \frac{1 + \sqrt{z}}{\sqrt{z} - 1}, & z > 1. \end{cases} \tag{6}$$

In the large-top mass limit, our LO impact factor reads

$$V_g^{(0)}(q) = \frac{\alpha_s^2}{v^2} \frac{\bar{q}^2}{72\pi^2 \sqrt{N_c^2 - 1}}. \tag{7}$$

The inclusion of the gluon PDF allows one to write differential proton-to-Higgs IF

$$dV_{p\to H}^{(0)}(q) = \frac{\alpha_s^2}{v^2} \frac{|\mathcal{F}(q^2)|^2}{128\pi^2 \sqrt{N_c^2 - 1}} q^2 dx_H f_g(x_H), \tag{8}$$

where the subscript $p$ in the left-hand-side denotes now the proton, $dx_H$ stands for the gluon/Higgs longitudinal momentum fraction. In order to establish the proper normalization for our impact factor, we insert into (8) a delta function depending on the produced Higgs-boson transverse momentum $\vec{p}_H$, then the LO result for the impact factor reads

$$\frac{dV_{p\to H}^{(0)}(q)}{\bar{q}^2} = \frac{\alpha_s^2}{v^2} \frac{|\mathcal{F}(q^2)|^2}{128\pi^2 \sqrt{N_c^2 - 1}} \int_0^1 dx_H f_g(x_H) d^2 \bar{p}_H \delta^{(2)}(\bar{p}_H - q). \tag{9}$$

For later convenience, we transfer the impact factor to the so called $(\nu, n)$-representation, i.e. we express it as superposition of the eigenfunctions of LO BFKL kernel. The outcome is the following:

$$dV_{p\to H}^{(0)}(\nu, n) = \int d^2 \bar{q} \frac{dV_{p\to H}^{(0)}(q)}{\bar{q}^2} \frac{(q^2)^{\nu - 1/2}}{\pi \sqrt{2}} e^{i\nu \phi}, \tag{10}$$

where $\phi$ is the azimuthal angle of the vector $\bar{q}$. Combining Eqs. (9) and (10), we get the following differential expression for our LO impact factor:

$$\frac{dV_{p\to H}^{(0)}(\nu, n)}{dx_H d^2 \bar{p}_H} = \frac{\alpha_s^2}{v^2} \frac{|\mathcal{F}(\bar{p}_H^2)|^2}{128\pi^3 \sqrt{2(N_c^2 - 1)}} (\bar{p}_H^2)^{\nu - 1/2} f_g(x_H) e^{i\nu \phi_H}, \tag{11}$$

where $\phi_H$ denotes the azimuthal angle of the vector $\bar{p}_H$.

For the sake of completeness, we give the corresponding expression for the jet LO impact factor [16]

$$\frac{d\Phi_{J}^{(0)}(\nu, n)}{dx_J d^2 \bar{p}_J} = 2\alpha_s \sqrt{\frac{C_F}{C_A}} (\bar{p}_J^2)^{\nu - 3/2} \left( \frac{C_A}{C_F} f_g(x_J) + \sum_{a=q\bar{q}} f_a(x_J) \right) e^{i\nu \phi_J}, \tag{12}$$

where
Figure 3: Representative Feynman diagram for the squared modulus of the amplitude for
the gluon scattering off a Reggeon to produce a Higgs particle. The Reggeized gluon is
depicted by the zigzag line.

where $\phi_J$ denotes the azimuthal angle of the vector $\vec{p}_J$.

In the next section we will build the cross section for the process of our consideration,
by combining the BFKL Green’s function and impact factor for the jet, together with our
calculated Higgs-gluon impact factor.

2.2 Cross section and azimuthal coefficients

For the sake of simplicity, we consider final-state configurations where the Higgs is always
tagged in a more forward direction with respect to the jet, thus implying $\Delta Y \equiv y_H - y_J > 0$.

As anticipated, the Higgs and the jet are also expected to feature large transverse
momenta, $|\vec{p}_H|^2 \sim |\vec{p}_J|^2 \gg \Lambda_{\text{QCD}}^2$. The four-momenta of the parent protons, $p_{1,2}$, are
taken as Sudakov vectors satisfying $p_2^2 = 0$ and $p_1 p_2 = s/2$, so that the final-state
transverse momenta can be decomposed in the following way:

$$p_H = x_H p_1 + \frac{M_{H,\perp}^2}{x_H s} p_2 + p_{H,\perp}, \quad p_{H,\perp} = -|\vec{p}_H|^2,$$

$$p_J = x_J p_2 + \frac{|\vec{p}_J|}{x_J s} p_1 + p_{J,\perp}, \quad p_{J,\perp} = -|\vec{p}_J|^2,$$  \hspace{1cm} (13)

with the space part of the four-vector $p_{1,\parallel}$ being taken positive; $M_{H,\perp} = \sqrt{M_H^2 + |\vec{p}_H|^2}$ is
the Higgs-boson transverse mass.
The longitudinal-momentum fractions, \( x_{H,J} \), for the Higgs and jet are related to the corresponding rapidities in the center-of-mass frame via the relations:
\[
y_H = \frac{1}{2} \ln \frac{x_H^2 s}{M_{H,\perp}^2}, \quad y_J = \frac{1}{2} \ln \frac{|\vec{p}_J|^2}{x_J^2 s}, \quad dy_{H,J} = \pm \frac{dx_{H,J}}{x_{H,J}}.
\]  
As for the rapidity distance, one has
\[
\Delta Y = y_H - y_J = \ln \frac{x_H x_J s}{M_{H,\perp} |\vec{p}_J|}.
\]

Using QCD collinear factorization to build the (differential) hadronic cross section, one has
\[
d\sigma = \sum_{i,j=q,\bar{q},g} \int_0^1 dx_1 \int_0^1 dx_2 \ f_i(x_1,\mu_{F_1}) f_j(x_2,\mu_{F_2}) \ \frac{d\hat{\sigma}_{i,j}(\hat{s},\mu_{F_{1,2}})}{dx_H dx_J d^2 \vec{p}_H d^2 \vec{p}_J},
\]
where the \( i, j \) indices run over the parton kinds (quarks \( q = u,d,s,c,b; \) antiquarks \( \bar{q} = \bar{u},\bar{d},\bar{s},\bar{c},\bar{b}; \) or gluon \( g \)), \( f_{i,j} (x, \mu_{F_{1,2}}) \) are the incoming-proton PDFs; \( x_{1,2} \) denote the longitudinal fractions of the partons involved in the hard subprocess, whereas \( \mu_{F_{1,2}} \) stand for the factorization scales characteristic of the two fragmentation regions of the incoming hadrons; \( d\hat{\sigma}_{i,j}(\hat{s}) \) is the partonic cross section, with \( \hat{s} \equiv x_1 x_2 s \) the squared center-of-mass energy of the parton-parton collision subreaction. In the present case, the sum over the parton kinds \( i \) restricts to the gluon contribution only, consistently with a LO treatment of the Higgs impact factor, as discussed in the previous section.

The BFKL cross section can be presented (see Ref. [31] for the derivation) as the Fourier series of the so-called azimuthal coefficients, \( C_n \)
\[
\frac{d\sigma}{dy_H dy_J d|\vec{p}_H| d|\vec{p}_J| d\varphi_H d\varphi_J} = \frac{1}{(2\pi)^2} \left[ C_0 + \sum_{n=1}^{\infty} 2 \cos(n\varphi) C_n \right],
\]
where \( \varphi = \varphi_H - \varphi_J - \pi \), with \( \varphi_{H,J} \) the Higgs and the jet azimuthal angles. A comprehensive formula for the \( \varphi \)-averaged cross section, \( C_0 \), and the other coefficients, \( C_{n>0} \), reads
\[
C_n \equiv \int_0^{2\pi} d\varphi_H \int_0^{2\pi} d\varphi_J \cos(n\varphi) \frac{d\sigma}{dy_H dy_J d|\vec{p}_H| d|\vec{p}_J| d\varphi_H d\varphi_J} = \frac{e^{\Delta Y}}{s} \frac{M_{H,\perp}}{|\vec{p}_H|} \times \int_{-\infty}^{+\infty} d\nu \left( \frac{x_J x_H s}{s_0} \right)^{\bar{a}_0(\mu_{R_{\nu}})} \chi(n,\nu) \chi(n,\nu) \left[ \bar{\chi}(n,\nu) + \frac{2\nu}{s_0} \chi(n,\nu) \right]^{-1/2} + \ln \left( \frac{\nu}{\sqrt{|\vec{p}_H|}} \right) \right]}
\]
8
\[
\times \left\{ \alpha_s(\mu_R) c_H(n, \nu, |\vec{p}_H|, x_H) \right\} \left\{ \alpha_s(\mu_R) [c_J(n, \nu, |\vec{p}_J|, x_J)]^* \right\} \\
\times \left\{ 1 + \alpha_s(\mu_R) \frac{c_H^{(1)}(n, \nu, |\vec{p}_H|, x_H)}{c_H(n, \nu, |\vec{p}_H|, x_H)} + \alpha_s(\mu_R) \left[ \frac{c_J^{(1)}(n, \nu, |\vec{p}_J|, x_J)}{c_J(n, \nu, |\vec{p}_J|, x_J)} \right]^* \right\}, \tag{18}
\]

where \( \bar{\alpha}_s \equiv N_c/\pi \alpha_s \), with \( N_c \) the QCD color number,

\[
\beta_0 = \frac{11}{3} N_c - \frac{2}{3} n_f \tag{19}
\]

the first coefficient in the expansion of the QCD \( \beta \)-function \( (n_f \text{ is the active-flavor number}) \),

\[
\chi(n, \nu) = 2 \psi(1) - \psi\left( \frac{n + 1}{2} + i\nu \right) - \psi\left( \frac{n + 1}{2} - i\nu \right) \tag{20}
\]

the eigenvalue of the LO BFKL kernel, \( c_{H,j}(n, \nu) \) are the Higgs and the jet LO impact factors in the \( (\nu, n) \)-space, given by

\[
c_H(n, \nu, |\vec{p}_H|, x_H) = \frac{1}{v^2} \frac{|\mathcal{F}(\vec{p}_H^2)|^2}{128 \pi^4 \sqrt{2(N_c^2 - 1)}} (\vec{p}_H^2)^{n+1/2} f_g(x_H, \mu_{F_1}), \tag{21}
\]

\[
c_J(n, \nu, |\vec{p}_J|, x_J) = 2 \sqrt{\frac{C_F}{C_A}} (\vec{p}_J^2)^{n-1/2} \left( \frac{C_A}{C_F} f_g(x_J, \mu_{F_2}) + \sum_{a=q,\bar{q}} f_a(x_J, \mu_{F_2}) \right). \tag{22}
\]

The energy-scale parameter, \( s_0 \), is arbitrary within NLA accuracy and will be fixed in our analysis at \( s_0 = M_{H,\perp} |\vec{p}_j| \). The remaining quantities are the NLO impact-factor corrections, \( c_{H,j}^{(1)}(n, \nu, |\vec{p}_H|, x_H) \). The expression for the Higgs NLO impact factor has not been yet calculated. It is possible, however, to include some “universal” NLO contributions to the Higgs impact factor, which can be expressed through the corresponding LO impact factor, and are fixed by the requirement of stability within the NLO under variations of the energy scale \( s_0 \), the renormalization scale \( \mu_R \) and of the factorization scale \( \mu_F \), getting

\[
\alpha_s c_H^{(1)}(n, \nu, |\vec{p}_H|, x_H) \to \bar{\alpha}_s c_H^{(1)}(n, \nu, |\vec{p}_H|, x_H), \tag{23}
\]

with

\[
\bar{c}_H^{(1)}(n, \nu, |\vec{p}_H|, x_H) = c_H(n, \nu, |\vec{p}_H|, x_H) \left\{ \frac{\beta_0}{4N_c} \left( 2 \ln \frac{\mu_{R_1}}{|\vec{p}_H|} + \frac{5}{3} \right) + \frac{\chi(n, \nu)}{2} \ln \left( \frac{s_0}{M_{H,\perp}^2} \right) \right\} + \frac{\beta_0}{4N_c} \left( 2 \ln \frac{\mu_{R_1}}{M_{H,\perp}} \right) \tag{24}
\]

\[
- \frac{1}{2N_c f_g(x_H, \mu_{F_1})} \ln \frac{\mu_{F_1}^2}{M_{H,\perp}^2} \int_{x_H}^{1} \frac{dz}{z} \left[ P_{gg}(z) f_g \left( \frac{x_H}{z}, \mu_{F_1} \right) + \sum_{a=q,\bar{q}} P_{ga}(z) f_a \left( \frac{x_H}{z}, \mu_{F_1} \right) \right] \right\}. \]
The jet impact factor is known at the NLO [13–17], nonetheless we treated it on the same ground as the Higgs one, including only the NLO corrections fixed by the renormalization group and leading to

\[
\tilde{c}_J^{(1)}(n, \nu, \tilde{p}_J, x_J) = c_J(n, \nu, |\tilde{p}_J|, x_J) \left\{ \frac{\beta_0}{4N_c} \left( 2 \ln \frac{\mu_{R_2}}{|\tilde{p}_J|} + \frac{5}{3} \right) + \frac{\chi(n, \nu)}{2} \ln \left( \frac{s_0}{|\tilde{p}_J|^2} \right) \right\} 
\]

\[
- \frac{1}{2N_c} \left( \frac{C_A}{C_F} f_g(x_J, \mu_{F_2}) + \sum_{a=q,\bar{q}} f_a(x_J, \mu_{F_2}) \right) \ln \frac{\mu_{F_2}^2}{|\tilde{p}_J|^2} 
\]

\[
\times \left( \frac{C_A}{C_F} \int_{x_J}^1 \frac{dz}{z} \left[ P_{gg}(z) f_g \left( \frac{x_J}{z}, \mu_{F_2} \right) + \sum_{a=q,\bar{q}} P_{ga}(z) f_a \left( \frac{x_J}{z}, \mu_{F_2} \right) \right] \right) + \sum_{a=q,\bar{q}} \int_{x_J}^1 \frac{dz}{z} \left[ P_{ag}(z) f_g \left( \frac{x_J}{z}, \mu_{F_2} \right) + P_{aa}(z) f_a \left( \frac{x_J}{z}, \mu_{F_2} \right) \right] \right\}.
\]

Combining all the ingredients, we can write our master formula for the azimuthal coefficients,

\[
C_n = \frac{e^{\Delta Y} M_{H,\perp}}{s} \left| \frac{\tilde{p}_H}{|\tilde{p}_H|} \right| \times \int_{-\infty}^{+\infty} d\nu \left( \frac{x_J x_H s}{s_0} \right) \tilde{c}_J(\nu, x_J) \left\{ \chi(n, \nu) + \bar{\alpha}_s(\mu_{R_2}) \left[ \chi(n, \nu) + \frac{\beta_0}{\pi s_0} \chi(n, \nu) - \chi(n, \nu) + \frac{\beta_0}{\pi s_0} \chi(n, \nu) + 4 \ln \left( \frac{s_0}{|\tilde{p}_H|} \right) \right] \right\}
\]

\[
\times \left\{ \alpha_s^2(\mu_{R_1}) c_H(n, \nu, |\tilde{p}_H|, x_H) \right\} \left\{ \bar{\alpha}_s(\mu_{R_3}) \left[ c_J(n, \nu, |\tilde{p}_J|, x_J) \right] \right\} \left\{ 1 + \bar{\alpha}_s(\mu_{R_1}) \frac{\tilde{z}_J^{(1)}(n, \nu, |\tilde{p}_J|, x_J)}{c_J(n, \nu, |\tilde{p}_J|, x_J)} + \bar{\alpha}_s(\mu_{R_3}) \frac{\tilde{c}_J^{(1)}(n, \nu, |\tilde{p}_J|, x_J)}{c_J(n, \nu, |\tilde{p}_J|, x_J)} \right\}.
\]

The renormalization scales ($\mu_{R_{1,2,3}}$) and the factorization ones ($\mu_{F_{1,2}}$) can, in principle, be chosen arbitrarily, since their variation produces effects beyond the NLO. It is however advisable to relate them to the physical hard scales of the process. We chose to fix them differently from each other, depending on the subprocess to which they are related: $\mu_{R_1} \equiv \mu_F = C_\mu M_{H,\perp}$, $\mu_{R_2} \equiv \mu_{F_2} = C_\mu |\tilde{p}_J|$, $\mu_{R_3} = C_\mu \sqrt{M_{H,\perp} |\tilde{p}_J|}$, where $C_\mu$ is a variation parameter introduced to gauge the effect of a change of the scale (see the discussion at the end of Section 3.2).

3 Phenomenology

3.1 Azimuthal correlations and $p_T$-distribution

The first observables of our consideration are the azimuthal-angle coefficients integrated over the phase space for two final-state particles, while the rapidity interval, $\Delta Y$, between
the Higgs boson and the jet is kept fixed:

\[
C_n(\Delta Y, s) = \int_{p_{H\min}^\max}^{p_{H\max}^\min} d|\vec{p}_H| \int_{p_{J\min}^\max}^{p_{J\max}^\min} d|\vec{p}_J| \int_{y_{H\min}^\max}^{y_{H\max}^\min} dy_H \int_{y_{J\min}^\max}^{y_{J\max}^\min} dy_J \delta (y_H - y_J - \Delta Y) C_n. \tag{27}
\]

Pursuing the goal of fitting realistic kinematic cuts adopted by the current experimental analyses at the LHC, we constrain the Higgs emission inside the rapidity acceptances of the CMS barrel detector, \( |y_H| < 2.5 \), while we allow for a larger rapidity range of the jet [98], which can be detected also by the CMS endcaps, namely \( |y_J| < 4.7 \). Furthermore, three distinct cases for the final-state transverse momenta are considered:

a) **symmetric** configuration, suited to the search of pure BFKL effects, where both the Higgs and the jet transverse momenta lie in the range: \( 20 \text{ GeV} < |\vec{p}_{H,J}| < 60 \text{ GeV} \);

b) **asymmetric** selection, typical of the ongoing LHC phenomenology, where the Higgs transverse momentum runs from 10 GeV to \( 2M_t \), where the jet is tagged inside its typical CMS configuration, from 20 to 60 GeV;

c) **disjoint windows**, which allows for the maximum exclusiveness in the final state: \( 35 \text{ GeV} < |\vec{p}_J| < 60 \text{ GeV} \) and \( 60 \text{ GeV} < |\vec{p}_H| < 2M_t \).

We study the \( \varphi \)-averaged cross section (alias the \( \Delta Y \)-distribution), \( C_0(\Delta Y, s) \), the azimuthal-correlation moments, \( R_{nm}(\Delta Y, s) = C_n/C_0 = \langle \cos n \varphi \rangle \), and their ratios, \( R_{nm} = C_n/C_m \) [86, 87] as functions of the Higgs-jet rapidity distance, \( \Delta Y \).

The second observable of our interest is the \( p_H \)-distribution for a given value of \( \Delta Y \):

\[
\frac{d\sigma(|\vec{p}_H|, \Delta Y, s)}{d|\vec{p}_H|d\Delta Y} = \int_{p_{J\min}^\max}^{p_{J\max}^\min} d|\vec{p}_J| \int_{y_{H\min}^\max}^{y_{H\max}^\min} dy_H \int_{y_{J\min}^\max}^{y_{J\max}^\min} dy_J \delta (y_H - y_J - \Delta Y) C_0, \tag{28}
\]

the Higgs and jet rapidity ranges being given above and \( 35 \text{ GeV} < |\vec{p}_J| < 60 \text{ GeV} \).

### 3.2 Results and discussion

In Fig. 4 we present results for the \( \Delta Y \)-distribution, \( C_0 \), in the three kinematic configurations under investigation. Here, the usual onset of the BFKL dynamics comes easily out. The growth with energy of the pure partonic cross sections is quenched by the convolution with PDFs, this leading to a lowering with \( \Delta Y \) of hadronic distributions. Notably, LLA predictions (blue) are almost entirely contained inside NLA uncertainty bands (red), thus corroborating the underlying assumption that the large energy scales provided by the emission of a Higgs boson stabilize the BFKL series. A further manifestation of this effect appears in the analysis of azimuthal correlations, \( R_{nm} \). For all the considered cases (Figs. 5, 6 and 7), higher-order corrections show a milder discrepancy with respect to
pure LLA ones. This represents a novel feature in the context of semi-hard reactions, where LLA moments have always shown a fairly stronger decorrelation than NLA ones. Previous studies of Mueller-Navelet jet production [33, 36, 38] have highlighted how the use of scale-optimization procedures is needed to bring NLA patterns near LLA ones and, ultimately, to match CMS data [98]. Conversely, Higgs-jet hadroproduction genuinely exhibits a solid stability under higher-order corrections in the range between 1/2 and two times the natural scales provided by kinematics, thus tracing the path towards possible precision studies of cross sections.

In Fig. 8 we present predictions for the $p_H$-distribution, $d\sigma/(d|p_H|d\Delta Y)$, in the range $10 \text{ GeV} < |p_H| < 2M_t$, and for two values of the rapidity interval, $\Delta Y = 3, 5$. Here, the Born contribution (green) corresponds to the so-called two-gluon approximation, which describes the back-to-back emission of the Higgs and of the jet with no additional gluon radiation. From the analytic point of view, one has

\[
\frac{d\sigma^{\text{Born}}(|p_H|, \Delta Y, s)}{d|p_H|d\Delta Y} = \pi \frac{e^{\Delta Y}}{s} M_{H, \perp} \int_{y_H^\text{min}}^{y_H^\text{max}} dy_H \int_{y_J^\text{min}}^{y_J^\text{max}} dy_J \delta(y_H - y_J - \Delta Y) \times \alpha_s^2(\mu_{R_1}) \frac{1}{v^2} \frac{|\mathcal{F}(\vec{p}_H^2)|^2}{128\pi^3 \sqrt{2(N_c^2 - 1)}} f_g(x_H, \mu_{F_1}) \times \alpha_s(\mu_{R_2}) 2 \sqrt{\frac{C_F}{C_A}} \left( \frac{C_A}{C_F} f_g(x_J, \mu_{F_2}) + \sum_{a=q,\bar{q}} f_a(x_J, \mu_{F_2}) \right). \tag{29}
\]

Our calculation in the Born limit at $\Delta Y = 3$ (left panel of Fig. 8) is in fair agreement with the corresponding pattern in Ref. [96] (solid line in the left panel of Fig. 2), up to a factor two, due to the fact that we restricted $\Delta Y$ to be positive, which means that the Higgs particle is always more forward than the jet\(^2\). In our study, this calculation cannot exceed a given upper cut-off in the $|p_H|$-range, say around 125 GeV. This is due to our choice for the final-state kinematic ranges, where consistency with experimental cuts in the rapidities of the detected objects would lead to $x_J > 1$ for sufficiently large jet transverse momenta.

Both the LLA (blue) and the NLA (red) series of Fig. 8 show a peak (not present in the Born case) at $|p_H|$ around 40 GeV for the two values of $\Delta Y$, and a decreasing behavior at large $|p_H|$. For the sake of simplicity, we distinguish three kinematic subregions. The low-$|p_H|$ region, i.e. $|p_H| < 10$ GeV, has been excluded from our analysis, since it is dominated by large transverse-momentum logarithms, which call for the corresponding all-order resummation [99], not accounted by our formalism. To the intermediate-$|p_H|$ region the set of configurations where $|p_H|$ is of the same order of $|p_J|$, which ranges from 35 to 60 GeV, corresponds. It is essentially the peak region plus the first part

\[^2\text{Note that in Ref. [96] the Higgs mass is a free parameter. We compare our result with the corresponding one at } M_H = 120 \text{ GeV.}\]
of the decreasing tail, where NLA bands are totally nested inside the LLA ones. Here, the impressive stability of the perturbative series unambiguously confirms the validity of our description at the hand of the BFKL resummation. Finally, in the large-|\vec{p}_H| region represented by the long tail, NLA distributions decouple from LLA ones and exhibit an increasing sensitivity to scale variation. Here, DGLAP-type logarithms together with threshold effects \cite{threshold} start to become relevant, thus spoiling the convergence of the high-energy series.

All these considerations brace the message that an exhaustive study of the |\vec{p}_H|-distribution would rely on a unified formalism where distinct resummations are concurrently embodied. In particular, the impact of the BFKL resummation could depend on the delicate interplay among the Higgs transverse mass, the Higgs transverse momentum and the jet transverse momentum entering, in logarithmic form, the expressions of partial NLO corrections to impact factors (see Eqs. (24) and (25)). Future studies including full higher-order corrections will allow us to further gauge the stability of our calculations.

### 3.3 Numerical specifics and uncertainty estimation

All the numerical studies were completed making use of JETHAD, a FORTRAN2008-PYTHON3 hybrid library under development at our Group, which has been recently employed in the analysis of hadron-jet correlations \cite{hadron-jet} and of the inclusive heavy-flavored jet-pair hadroproduction \cite{inclusive-jet}. An auxiliary, independent MATHEMATICA interface allowed us to test the numerical reliability of our results. Quark and gluon PDFs were calculated through the MMHT2014 NLO PDF set \cite{MMHT2014} as provided by the LHAPDFv6.2.1 interpolator \cite{LHAPDF}, whereas we selected a two-loop running coupling setup with $\alpha_s (M_Z) = 0.11707$ and with dynamic-flavor threshold.

The two relevant sources of numerical uncertainty respectively come from the multidimensional integration over the final-state phase space (together with the oscillatory $\nu$-distribution) and from the one-dimensional integral over the longitudinal momentum fraction $\zeta$ in the NLO impact factor corrections (Eqs. (24) and (25)). They were directly estimated by the JETHAD integration tools. Other potential uncertainties, as the upper cutoff in the numerical integrations over $|\vec{p}_H|$, $|\vec{p}_J|$ and the $\nu$-variable, turned out to be negligible with respect to the first ones.

Furthermore, we gauged the effect of concurrently varying the renormalization scales ($\mu_{R_{1,2}}$) and the factorization ones ($\mu_{F_{1,2}}$) of them around their *natural* values in the range $1/2$ to two. The parameter $C_\mu$ entering the inset of panels in Figs. 4, 5, 6, 7 and 8 gives the ratio

$$C_\mu = \frac{\mu_{R,F_1}}{M_{H,\perp}} = \frac{\mu_{R,F_2}}{|\vec{p}_J|} = \frac{\mu_{R,c}}{\sqrt{M_{H,\perp}|\vec{p}_J|}}.$$  \hfill (30)
4 Conclusions and Outlook

We have proposed the inclusive hadroproduction of a Higgs boson and of a jet featuring high transverse momenta and separated by a large rapidity distance as a new diffractive semi-hard channel to probe the BFKL resummation. Statistics for cross sections differential in rapidity, tailored on different configurations for transverse-momentum ranges at CMS, is encouraging. At variance with previous analyses, where other kinds of final states were investigated, cross sections and azimuthal correlations for the Higgs-jet production exhibit quite a fair stability under higher-order corrections. Future analyses are needed in order to gauge the feasibility of precision calculations of the same observables. We have extended our study to distributions differential in the Higgs transverse momentum, providing evidence that a high-energy treatment is valid and can be afforded in the region where Higgs $p_T$ and the jet one are of the same order.

An obvious extension of this work consists in the full NLA BFKL analysis, including a NLO jet impact factor, with a realistic implementation of the jet selection function, and the NLO Higgs impact factor, when available.

Figure 4: $\Delta Y$-dependence of the $\varphi$-averaged cross section, $C_0$, for the inclusive Higgs-jet hadroproduction in the three considered $p_T$-ranges and for $\sqrt{s} = 14$ TeV. Shaded bands give the combined effect of the scale variation with the uncertainty coming from the phase-space numerical integration.
Figure 5: ∆Y-dependence of several ratios $R_{nn} \equiv C_n/C_m$, for the inclusive Higgs-jet hadroproduction in the $p_T$-symmetric configuration and for $\sqrt{s} = 14$ TeV. Shaded bands give the combined effect of the scale variation with the uncertainty coming from the phase-space numerical integration.
Figure 6: $\Delta Y$-dependence of several ratios $R_{nm} \equiv C_n/C_m$, for the inclusive Higgs-jet hadroproduction in the $p_T$-asymmetric configuration and for $\sqrt{s} = 14$ TeV. Shaded bands give the combined effect of the scale variation with the uncertainty coming from the phase-space numerical integration.
Figure 7: $\Delta Y$-dependence of several ratios $R_{nm} \equiv C_n/C_m$, for the inclusive Higgs-jet hadroproduction in the disjoint $p_T$-windows configuration and for $\sqrt{s} = 14$ TeV. Shaded bands give the combined effect of the scale variation with the uncertainty coming from the phase-space numerical integration.
Figure 8: $p_T$-dependence of the cross section for the inclusive Higgs-jet hadroproduction for $35 \text{ GeV} < p_T < 60 \text{ GeV}$, $\sqrt{s} = 14 \text{ TeV}$ and for $\Delta Y = 3, 5$. Shaded bands give the combined effect of the scale variation with the uncertainty coming from the phase-space numerical integration.
