Abstract. In our quest for the design, the analysis and the implementation of a subdivision algorithm for finding the complex roots of univariate polynomials given by oracles for their evaluation, we present subalgorithms allowing substantial acceleration of subdivision for complex roots clustering for such polynomials. We rely on Cauchy sums which approximate power sums of the roots in a fixed complex disc and can be computed in a small number of evaluations –polylogarithmic in the degree. We describe root exclusion, root counting, root radius approximation and a procedure for contracting a disc towards the cluster of root it contains, called $\varepsilon$-compression. To demonstrate the efficiency of our algorithms, we combine them in a prototype root clustering algorithm. For computing clusters of roots of polynomials that can be evaluated fast, our implementation competes advantageously with user’s choice for root finding, MPsolve.

Keywords: Polynomial Root Finding, Subdivision Algorithms, Oracle Polynomials

1 Introduction

We consider the

\varepsilon-Complex Root Clustering Problem ($\varepsilon$-CRC)

\textbf{Given:} a polynomial $p \in \mathbb{C}[z]$ of degree $d$, $\varepsilon > 0$
\textbf{Output:} $\ell \leq d$ couples $(\Delta^1, m^1), \ldots, (\Delta^\ell, m^\ell)$ satisfying:
- the $\Delta^j$’s are pairwise disjoint discs of radii $\leq \varepsilon$,
- for any $1 \leq j \leq \ell$, $\Delta^j$ and $3\Delta^j$ contain $m^j > 0$ roots of $p$,
- each complex root of $p$ is in a $\Delta^j$ for some $j$.

Here and hereafter root(s) stands for root(s) of $p$ and are counted with multiplicities, $3\Delta^j$ for the factor 3 concentric dilation of $\Delta^j$, and $p$ is a Black box polynomial: its coefficients are not known, but we are given evaluation oracles, that is, procedures for the evaluation of $p$, its derivative $p'$ and hence the ratio $p'/p$ at a point $c \in \mathbb{C}$ with a fixed precision. Such a black box polynomial
can come from an experimental process or can be defined by a procedure, for example Mandelbrot’s polynomials, defined inductively as
\[ \text{Man}_1(z) = z, \quad \text{Man}_k(z) = z \cdot \text{Man}_{k-1}(z)^2 + 1. \]
\( \text{Man}_k(z) \) has degree \( d = 2^k - 1 \) and \( d \) non-zero coefficients but can be evaluated fast, i.e. in \( O(k) \) arithmetic operations. Any polynomial given by its coefficients can be handled as a black box polynomial, and the evaluation subroutines for \( p, p' \) and \( p'/p \) are fast if \( p \) is sparse or Mandelbrot-like. One can solve root-finding problems and in particular the \( \epsilon \)-CRC problem for black box polynomials by first retrieving the coefficients by means of evaluation-interpolation, e.g., with FFT and inverse FFT, and then by applying the algorithms of [2,10,12,18].
Evaluation-interpolation, however, decompresses the representation of a polynomial, which can blow up its input length, in particular, can destroy sparsity. We do not require knowledge of the coefficients of an input polynomial, but instead use evaluation oracles.

Functional root-finding iterations such as Newton’s, Weierstrass’s (aka Durand-Kerner’s) and Ehrlich’s iterations – implemented in \texttt{MPSolve} [4] – can be applied to approximate the roots of black box polynomials. Applying such iterations, however, requires initial points, which the known algorithms and in particular \texttt{MPSolve} obtain by computing root radii, and for that it needs the coefficients of the input polynomial.

**Subdivision algorithms** Let \( i \) stand for \( \sqrt{-1} \), \( c \in \mathbb{C} \), \( c = a + ib \) and \( r, w \in \mathbb{R} \), \( r \) and \( w \) positive. We call box a square complex interval of the form \( B(c, w) := [a - \frac{w}{2}, a + \frac{w}{2}] + i[b - \frac{w}{2}, b + \frac{w}{2}] \) and disc \( D(c, r) \) the set \( \{ x \in \mathbb{C} \mid |x - c| \leq r \} \). The containing disc \( D(B(c, w)) \) of a box \( B(c, w) \) is \( D(c, (3/4)w) \). For a \( \delta > 0 \) and a box or a disc \( S \), \( \delta S \) denotes factor \( \delta \) concentric dilation of \( S \).

We consider algorithms based on iterative subdivision of an initial box \( B_0 \) (see [2,3,11]) and adopt the framework of [2,3] which relies on two basic subroutines: an Exclusion Test (ET) – deciding that a small inflation of a disc contains no root – and a Root Counter (RC) – counting the number of roots in a small inflation of a disc. A box \( B \) of the subdivision tree is tested for root exclusion or inclusion by applying the ET and RC to \( 2B \), which can fail and return \(-1\) when \( D(B) \) has some roots near its boundary circle. In [2], ET and RC are based on the Pellet’s theorem, requiring the knowledge of the coefficients of \( p \) and shifting the center of considered disc into the origin (Taylor’s shifts); then Dandelin-Lobachevsky-Gräffe iterations, aka root-squaring iterations, enable the following properties for boxes \( B \) and discs \( \Delta \):

1. if \( 2B \) contains no root, ET applied to \( D(B) \) returns 0,
2. if \( \Delta \) and \( 4\Delta \) contain \( m \) roots, RC applied to \( 2\Delta \) returns \( m \).

(p1) and (p2) bound the depth of the subdivision tree. To achieve quadratic convergence to clusters of roots, [2] uses a complex version of the Quadratic Interval Refinement iterations of J. Abbott [11], aka QIR Abbott iterations, described in details in Algo. 7 of [3] and, like [11], based on extension of Newton’s iterations to multiple roots due to Schröder. [7] presents an implementation of
in the C library Ccluster which slightly outperforms M Psolve for initial boxes containing only few roots.

In [6] we applied an ET based on Cauchy sums approximation. It satisfies (p1) and instead of coefficients of \( p \) involves \( O(\log^2 d) \) evaluations of \( \frac{p'}{p} \) with precision \( O(d) \) for a disc with radius in \( O(1) \); although the output of this ET is only certified if no roots lie on or near the boundary of the input discs, in our extensive experiments it was correct when we dropped this condition.

1.1 Our contributions

The ultimate goal of our work is to design an algorithm for solving the \( \varepsilon \)-CRC problem for black box polynomials which would run faster in practice than the known solvers, have low and possibly near optimal Boolean complexity. We do not achieve this yet in this paper but rather account for the advances along this path by presenting several sub-routines for root clustering. We implemented and assembled them in an experimental \( \varepsilon \)-CRC algorithm which outperforms the user’s choice software for complex root finding, M Psolve, for input polynomials that can be evaluated fast.

Cauchy ET and RC We describe and analyze a new RC based on Cauchy sum computations and satisfying property (p2) which only require the knowledge of evaluation oracles. For input disc of radius in \( O(1) \), it requires evaluation of \( \frac{p'}{p} \) at \( O(\log^2 d) \) points with precision \( O(d) \) and is based on our ET presented in [6]; the support for its correctness is only heuristic.

Disc compression For a set \( S \), let us write \( Z(S,p) \) for the set of roots in \( S \) and \#(\( S,p \)) for the cardinality of \( Z(S,p) \); two discs \( \Delta \) and \( \Delta' \) are said equivalent if \( Z(\Delta,p) = Z(\Delta',p) \). We introduce a new sub-problem of \( \varepsilon \)-CRC:

\textbf{\( \varepsilon \)-Compression into Rigid Disc (\( \varepsilon \)-CRD)}

\textbf{Given}: a polynomial \( p \in \mathbb{C}[z] \) of degree \( d \), \( \varepsilon > 0 \), \( 0 < \gamma < 1 \), a disc \( \Delta \) s.t. \( Z(\Delta,p) \neq \emptyset \) and \( 4\Delta \) is equivalent to \( \Delta \).

\textbf{Output}: a disc \( \Delta' \subseteq \Delta \) of radius \( r' \) s.t. \( \Delta' \) is equivalent to \( \Delta \) and:
- either \( r' \leq \varepsilon \),
- or \( \#(\Delta,p) \geq 2 \) and \( \Delta' \) is at least \( \gamma \)-rigid, that is

\[
\max_{\alpha,\alpha' \in Z(\Delta',p)} \frac{|\alpha - \alpha'|}{2r'} \geq \gamma.
\]

The \( \varepsilon \)-CRD problem can be solved with subdivision and QIR Abbott iteration, but this may require, for an initial disk of radius \( r \), up to \( O(\log(r/\max(\varepsilon, \varepsilon')) \) calls to the ET in the subdivision if the radius of convergence of the cluster in \( \Delta \) for Schröder’s iteration is in \( O(\varepsilon') \).

We present and analyze an algorithm solving the \( \varepsilon \)-CRD problem for \( \gamma = 1/8 \) based on Cauchy sums approximation and on an algorithm solving the following

https://github.com/rimbach/Ccluster
root radius problem: for a given $c \in \mathbb{C}$, a given non-negative integer $m \leq d$ and a $\nu > 1$, find $r$ such that $r_m(c, p) \leq r \leq \nu r_m(c, p)$ where $r_m(c, p)$ is the smallest radius of a disc centered in $c$ and containing exactly $m$ roots of $p$. Our compression algorithm requires only $O(\log \log(r/\epsilon))$ calls to our RC, but a number of evaluations and arithmetic operations increasing linearly with $\log(1/\epsilon)$.

Experimental results We implemented our algorithms within Ccluster and assembled them in two algorithms named CauchyQIR and CauchyComp for solving the $\epsilon$-CRC problem for black box polynomials. Both implement the subdivision process of [2] with our heuristically correct ET and RC, and

- CauchyQIR uses QIR Abbott iterations of [3] (with Pellet’s test replaced by our RC)
- CauchyComp uses our compression algorithm instead of QIR Abbott iterations.

We compare runs of CauchyQIR and CauchyComp to emphasize the practical improvements allowed by using compression in subdivision algorithms for root finding. We also compare running times of CauchyComp and MPsolve to demonstrate that subdivision root finding can outperform solvers based on functional iterations for polynomials that can be evaluated fast. MPsolve does not cluster roots of a polynomial, but approximate each root up to a given error $\epsilon$. Below we used the latest version of MPsolve and call it with: `mpsolve -as -Ga -j1 -oN` where N stands for max(1, $\lceil \log_{10}(1/\epsilon) \rceil$).

All the timings given below have to be understood as sequential running times on an Intel(R) Core(TM) i7-8700 CPU @ 3.20GHz machine with Linux. We present in table 1 results obtained for Mandelbrot and Mignotte polynomials

Table 1. Runs of CauchyQIR, CauchyComp and MPsolve on Mignotte and Mandelbrot polynomials.

|     | CauchyQIR | CauchyComp | MPsolve |
|-----|-----------|------------|---------|

4 they are not publicly released yet
5 3.2.1 available here: [https://numpi.dm.unipi.it/software/mpsolve](https://numpi.dm.unipi.it/software/mpsolve)
of increasing degree \(d\) for decreasing error \(\varepsilon\). The Mignotte polynomial of degree \(d\) and parameter \(a\) is defined as

\[
\text{Mig}_{d,a}(z) = z^d - 2(2a^2 - 1)z - 1.
\]

In Table 1, we account for the running time \(t\) for the three above-mentioned solvers. For CauchyQIR (resp. CauchyComp), we also give the number \(n\) of exclusion tests in the subdivision process, and the time \(t_N\) (resp. \(t_C\)) spent in QIR Abbott iterations (resp. compression). Mignotte polynomials have two roots with mutual distance close to the theoretical separation bound; with the \(\varepsilon\) used in Table 1, those roots are not separated.

### 1.2 Related Work

The subdivision root-finders of Weyl 1924, Henrici 1974, Renegar 1987, [11], rely on ET, RC and root radii sub-algorithms and heavily use the coefficients of \(p\). Design and analysis of subdivision root-finders for a black box \(p\) have been continuing since 2018 in [15] (now over 150 pages), followed by [5,6,9,13,14] and this paper. This relies on the novel idea and techniques of compression of a disc and on novel ET, RC and root radii sub-algorithms. A basic tool of Cauchy sum computation was used in [19] for polynomial deflation, but in a large body of our results only Thm. 5 is from [19]; we deduced it in [5,15] from a new more general theorem of independent interest. Alternative derivation and analysis of subdivision in [15] (yielding a little stronger results but presently not included) relies on Schröder’s iterations, extended from [11]. The algorithms are analyzed in [9,13,14,15], under the model for black box polynomial root-finding of [8]. [5,6] complement this study with some estimates for computational precision and Boolean complexity. We plan to complete them using much more space (cf. 46 pages in each of [19] and [3]). Meanwhile we borrowed from [3] Pellet’s RC (involving coefficients), Abbott’s QIR and the general subdivision algorithm with connected components of boxes extended from [11,17]. With our novel sub-algorithms, however, we significantly outperform \texttt{MPsolve} for polynomials that can be evaluated fast; all previous subdivision root-finders have never come close to such level. \texttt{MPsolve} relies on Ehrlich’s (aka Aberth’s) iterations, whose Boolean complexity is proved to be unbounded because iterations diverge for worst case inputs [10], but divergence never occurs in decades of extensive application of these iterations.

### 1.3 Structure of the paper

In Sec. 2 we describe power sums and their approximation with Cauchy sums. In Sec. 3 we present and analyze our Cauchy ET and RC. Sec. 4 is devoted to root...
radii algorithms and Sec. [5] to the presentation of our algorithm solving the ε-CRD problem. We describe the experimental solvers CauchyQIR and CauchyComp in Sec. [6] numeric results in Sec. [7] and conclude in Sec. [8]. We introduce additional definitions and properties in the rest of this section.

1.4 Definitions and two evaluations bounds

Throughout this paper, log is the binary logarithm and for a positive real number $a$, let $\log a = \max(1, \log a)$.

**Annuli, intervals** For $c \in \mathbb{C}$ and positives $r \leq r' \in \mathbb{R}$, the annulus $A(c, r, r')$ is the set $\{z \in \mathbb{C} : r \leq |z - c| \leq r'\}$.

Let $\mathfrak{I}(\mathbb{R})$ be the set $\{[a - \frac{w}{2}, a + \frac{w}{2}] : a, w \in \mathbb{R}, w \geq 0\}$ of real intervals. For $\mathfrak{I}a = [a - \frac{w}{2}, a + \frac{w}{2}] \in \mathfrak{I}(\mathbb{R})$ the center $c(\mathfrak{I}a)$, the width $w(\mathfrak{I}a)$ and the radius $r(\mathfrak{I}a)$ of $\mathfrak{I}a$ are respectively $a$, $w$ and $w/2$.

Let $\mathfrak{I}(\mathbb{C})$ be the set $\{[a + i\mathfrak{I}b] : a, b \in \mathfrak{I}(\mathbb{R})\}$ of complex intervals. If $\mathfrak{I}c \in \mathfrak{I}(\mathbb{C})$, then $w(\mathfrak{I}c)$ (resp. $r(\mathfrak{I}c)$) is $\max(w(\mathfrak{I}a), w(\mathfrak{I}b))$ (resp $w(\mathfrak{I}c)/2$). The center $c(\mathfrak{I}c)$ of $\mathfrak{I}c$ is $c(\mathfrak{I}a) + ic(\mathfrak{I}b)$.

**Isolation and rigidity of a disc** are defined as follows [11][15].

**Definition 1 (Isolation)** Let $\theta > 1$. The disc $\Delta = D(c, r)$ has isolation $\theta$ for a polynomial $p$ or equivalently is at least $\theta$-isolated if $Z\left(\frac{1}{\theta} \Delta, p\right) = Z(\Delta, p)$, that is $Z(A(c, r/\theta, r\theta), p) = \emptyset$.

**Definition 2 (Rigidity)** For a disc $\Delta = D(c, r)$, define

$$\gamma(\Delta) = \max_{a, a' \in Z(\Delta, p)} \frac{|a - a'|}{2r}$$

and remark that $\gamma(\Delta) \leq 1$. We say that $\Delta$ has rigidity $\gamma$ or equivalently is at least $\gamma$-rigid if $\gamma(\Delta) \geq \gamma$.

**Oracle Numbers and Oracle Polynomials** Our algorithms deal with numbers that can be approximated arbitrarily closely by a Turing machine. We call such approximation automata oracle numbers and formalize them through interval arithmetic.

For $a \in \mathbb{C}$ we call oracle for $a$ a function $O_a : \mathbb{N} \rightarrow \mathfrak{I}(\mathbb{C})$ such that $a \in O_a(L)$ and $r(\mathfrak{I}a(L)) \leq 2^{-L}$ for any $L \in \mathbb{N}$. In particular, one has $|c(\mathfrak{I}a(L)) - a| \leq 2^{-L}$. Let $O_{\mathbb{C}}$ be the set of oracle numbers which can be computed with a Turing machine. For a polynomial $p \in \mathbb{C}[z]$, we call evaluation oracle for $p$ a function $I_p : (O_{\mathbb{C}}, \mathbb{N}) \rightarrow \mathfrak{I}(\mathbb{C})$, such that if $O_a$ is an oracle for $a$ and $L \in \mathbb{N}$, then $p(a) \in I_p(O_a, L)$ and $r(I_p(O_a, L)) \leq 2^{-L}$. In particular, one has $|c(I_p(O_a, L)) - p(a)| \leq 2^{-L}$.

Consider evaluation oracles $I_p$ and $I_{p'}$ for $p$ and $p'$. If $p$ is given by $d' \leq d + 1$ oracles for its coefficients, one can easily construct $I_p$ and $I_{p'}$ by using, for instance, Horner’s rule. However for procedural polynomials (e.g. Mandelbrot), fast evaluation oracles $I_p$ and $I_{p'}$ are built from procedural definitions.
To simplify notations, we let \( I_p(a,L) \) stand for \( I_p(Oa,L) \). In the rest of the paper, \( P \) (resp. \( P' \)) is an evaluation oracle for \( p \) (resp. \( p' \)); \( P(a,L) \) (resp. \( P'(a,L) \)) will stand for \( I_p(Oa,L) \) (resp. \( I_p'(Oa,L) \)).

Two evaluation bounds The Lemma below is proved in A.1 and provides estimates for values of \(|p|\) and \(|p'/p|\) on the boundary of isolated discs.

Lemma 3 Let \( D(c,r) \) be at least \( \theta \)-isolated, \( z \in \mathbb{C}, |z| = 1 \) and \( g \) be a positive integer. Let \( \text{lcf}(p) \) be the leading coefficient of \( p \). Then

\[
|p(c + rz^g)| \geq |\text{lcf}(p)| \frac{r^d(\theta - 1)^d}{\theta^d} \quad \text{and} \quad \left| \frac{p'(c + rz^g)}{p(c + rz^g)} \right| \leq \frac{d\theta}{r(\theta - 1)}.
\]

2 Power Sums and Cauchy Sums

Definition 4 (Power sums of the roots in a disc) The \( h \)-th power sum of (the roots of) \( p \) in the disc \( D(c,r) \) is the complex number

\[
s_h(p,c,r) = \sum_{\alpha \in \mathbb{Z} \setminus \{0\}} \#(\alpha,p) \alpha^h
\]

where \( \#(\alpha,p) \) stands for the multiplicity of \( \alpha \) as a root of \( p \).

The power sums \( s_h(p,c,r) \) are equal to Cauchy’s integrals over the boundary circle \( \partial D(c,r) \); by following [19] they can be approximated by Cauchy sums obtained by means of the discretization of the integrals: let \( q \geq 1 \) be an integer and \( \zeta \) be a primitive \( q \)-th root of unity. When \( p(c + r\zeta^g) \neq 0 \) for \( g = 0, \ldots, q-1 \), and in particular when \( D(c,r) \) is at least \( \theta \)-isolated with \( \theta > 1 \), define the Cauchy sum \( \tilde{s}_h^q(p,c,r) \) as

\[
\tilde{s}_h^q(p,c,r) = \frac{r}{q} \sum_{g=0}^{q-1} \zeta^{q(h+1)} \frac{p'(c + r\zeta^g)}{p(c + r\zeta^g)}
\]

For conciseness of notations, we write \( s_h \) for \( s_h(p,0,1) \) and \( \tilde{s}_h^q \) for \( \tilde{s}_h^q(p,0,1) \). The following theorem, proved in [6,19], allows us to approximate power sums by Cauchy sums in \( D(0,1) \).

Theorem 5 For \( \theta > 1 \) and integers \( h,q \) s.t. \( 0 \leq h < q \) let the unit disc \( D(0,1) \) be at least \( \theta \)-isolated and contain \( m \) roots of \( p \). Then

\[
|\tilde{s}_h^q - s_h| \leq \frac{m\theta^{-h} + (d - m)\theta^h}{\theta^q - 1}.
\]

Fix \( e > 0 \). If \( q \geq \lfloor \log_\theta \left( \frac{d}{e} \right) \rfloor + h + 1 \) then \( |\tilde{s}_h^q - s_h| \leq e \).

Remark that \( s_0(p,c,r) \) is the number of roots of \( p \) in \( D(c,r) \) and \( s_1(p,c,r)/m \) is their center of gravity when \( m = \#(D(c,r),p) \).

Next we extend Thm. 5 to the approximation of 0-th and 1-st power sums by Cauchy sums in any disc, and define and analyze our basic algorithm for the computation of these power sums.
2.1 Approximation of the power sums

Let $\Delta = D(c, r)$ and define $p_\Delta(z)$ as $p(c + rz)$ so that $\alpha$ is a root of $p_\Delta$ in $D(0,1)$ if and only if $c + r\alpha$ is a root of $p$ in $\Delta$. Following Newton’s identities, one has:

\begin{align*}
    s_0(p,c,r) &= s_0(p_\Delta,0,1), \\
    s_1(p,c,r) &= cs_0(p_\Delta,0,1) + rs_1(p_\Delta,0,1).
\end{align*}

Next since $p'_\Delta(z) = rp'(c + rz)$, one has

\[ \tilde{s}_h^q(p,c,r) = \frac{1}{q} \sum_{g=0}^{q-1} \zeta^{q(h+1)} \frac{p'_\Delta(\zeta^g)}{p_\Delta(\zeta^g)} = \tilde{s}_h^q(p_\Delta,0,1) \]

and can easily prove:

**Corollary 6 (of thm. [5])** Let $\Delta = D(c, r)$ be at least $\theta$-isolated. Let $q > 1$, $s_0 = \tilde{s}_0^q(p,c,r)$ and $s_1^* = \tilde{s}_1^q(p,c,r)$. Let $e > 0$. One has

\[ |s_0^* - s_0(p,c,r)| \leq \frac{d}{\theta^e - 1}. \tag{7} \]

If $q \geq \lfloor \log_d(1 + \frac{d}{e}) \rfloor$ then $|s_0^* - s_0(p,c,r)| \leq e$.

Let $\Delta$ contain $m$ roots.

\[ |mc + rs_1^* - s_1(p,c,r)| \leq \frac{rd\theta}{\theta^e - 1}. \tag{9} \]

If $q \geq \lfloor \log_d(1 + \frac{r\theta d}{e}) \rfloor$ then $|mc + rs_1^* - s_1(p,c,r)| \leq e$.

2.2 Computation of Cauchy sums

Next we suppose that $D(c, r)$ and $q$ are such that $p(c + rz) \neq 0 \forall 0 \leq q < q$, so that $\tilde{s}_h^q(p,c,r)$ is well defined. We approximate Cauchy sums with evaluation oracles $P$, $P'$ by choosing a sufficiently large $L$ and computing the complex interval:

\[ \Box \tilde{s}_h^q(p,c,r,L) = \frac{r}{q} \sum_{g=0}^{q-1} O_{\zeta^{q(h+1)}}(L) \frac{P'(e + r\zeta^q, L)}{P(e + r\zeta^q, L)}. \tag{11} \]

$\Box \tilde{s}_h^q(p,c,r,L)$ is well defined for $L > \max_{0 \leq q < q} (\log_2(p(c + rz)))$ and contains $\tilde{s}_h^q(p,c,r)$. The following result specifies $L$ for which we obtain that $r(\Box \tilde{s}_h^q(p,c,r,L)) \leq e$ for an $e > 0$. It is proved in A.2

**Lemma 7** For strictly positive integer $d$, reals $r$ and $e$ and $\theta > 1$, let

\[ L(d,r,e,\theta) := \max \left( (d + 1) \log \frac{\theta}{cr(\theta - 1)} + \log(26rd), 1 \right) \in O \left( d \left( \log \frac{1}{re} + \log \frac{\theta}{\theta - 1} \right) \right). \]

If $L \geq L(d,r,e,\theta)$ then $r(\Box \tilde{s}_h^q(p,c,r,L)) \leq e$.

In the sequel let $L(d,r)$ stand for $L(d,r,1/4,2)$. 

\[ \]
2.3 Approximating the power sums $s_0, s_1, \ldots, s_h$

Our Algo. 1 computes, for a given integer $h$, approximations to power sums $s_0, s_1, \ldots, s_h$ (of $p_{\Delta}$ in $D(0,1)$) up to an error $e$, based on eqs. (2) and (4).

**Algorithm 1 ApproxShs**($\mathcal{P}, \mathcal{P}', \Delta, \theta, h, e$)

**Require:** $\mathcal{P}, \mathcal{P}'$ evaluation oracles for $p$ and $p'$, s.t. $p$ is monic of degree $d$. $\Delta = D(c, r)$, $\theta \in \mathbb{R}, \theta > 1$, $h \in \mathbb{N}$, $h \geq 0$, $e \in \mathbb{R}$, $e > 0$.

**Ensure:** a flag success $\in \{true, false\}$, a vector $[\mathcal{B}_0, \ldots, \mathcal{B}_h]$.

1. $c' \leftarrow e/4$, $q \leftarrow \lceil \log_\theta (4d/e) \rceil + h + 1$
2. $\ell \leftarrow \frac{e^2}{\theta^{(q-1)d}}$, $\ell' \leftarrow \frac{d\theta}{r^{(q-1)}}$
3. $L \leftarrow 1 - 2\ell$
4. $[\mathcal{B}_0, \ldots, \mathcal{B}_h] \leftarrow [C, \ldots, C]$
5. while $\exists i \in \{0, \ldots, h\}$ s.t. $w(\mathcal{B}_i) \geq e$ do
6. $L \leftarrow 2L$
7. for $g = 0, \ldots, q - 1$ do
8. Compute intervals $\mathcal{P}(c + r\zeta^g, L)$ and $\mathcal{P}'(c + r\zeta^g, L)$
9. if $\exists g \in \{0, \ldots, q - 1\}$ s.t. $|\mathcal{P}(c + r\zeta^g, L)| < \ell$ or $\left| \frac{\mathcal{P}'(c + r\zeta^g, L)}{\mathcal{P}(c + r\zeta^g, L)} \right| > \ell'$ then
10. return false, $[\mathcal{B}_0, \ldots, \mathcal{B}_h]$
11. if $\exists g \in \{0, \ldots, q - 1\}$ s.t. $\frac{e}{L} \in |\mathcal{P}(c + r\zeta^g, L)|$ or $2\ell' \in \left| \frac{\mathcal{P}'(c + r\zeta^g, L)}{\mathcal{P}(c + r\zeta^g, L)} \right|$ then
12. continue
13. for $i = 0, \ldots, h$ do
14. $\mathcal{B}_i \leftarrow \mathcal{B}_i \cup (p, c, r, L)$ \quad //as in eq. (12)
15. $\mathcal{B}_i \leftarrow \mathcal{B}_i \cup [-e', e']$ + $i[-e', e']$
16. return true, $[\mathcal{B}_0, \ldots, \mathcal{B}_h]$

Algo. 1 satisfies the following proposition proved in A.3.

**Proposition 8** Algo. 1 terminates for an $L \leq D(d, r, e/4, \theta)$.

Let **ApproxShs**($\mathcal{P}, \mathcal{P}', \Delta, \theta, h, e$) return (success, $[\mathcal{B}_0, \ldots, \mathcal{B}_h]$). Let $\Delta = D(c, r)$ and $p_{\Delta}(z) = p(c + rz)$. If $\theta > 1$, one has:

(a) If $A(c, r/\theta, r\theta)$ contains no root of $p$, then success $= true$ and for all $i \in \{0, \ldots, h\}$, $w(\mathcal{B}_i) < e$ and $\mathcal{B}_i$ contains $s_i(p_{\Delta}, 0, 1)$.

(b) If $e \leq 1$ and $D(c, r\theta)$ contains no root of $p$ then success $= true$ and for all $i \in \{0, \ldots, h\}$, $\mathcal{B}_i$ contains the unique integer 0.

(c) If $e \leq 1$ and $A(c, r/\theta, r\theta)$ contains no root of $p$, $\mathcal{B}_0$ contains the unique integer $s_0(p, c, r) = \#(\Delta, p)$.

(d) If success $= false$, then $A(c, r/\theta, r\theta)$ and $D(c, r\theta)$ contain (at least) a root of $p$.

(e) If success $= true$ and $\exists i \in \{0, \ldots, h\}$, s.t. $\mathcal{B}_i$ does not contain 0 then $A(c, r/\theta, r\theta)$ and $D(c, r\theta)$ contains (at least) a root of $p$.

3 Exclusion Test and Root Counters

In this section we define and analyse our base tools for disc exclusion and root counting. We recall in subsec. 3.1 and subsec. 3.2 the RC and the ET presented.
In subsec. 3.3, we propose a heuristic certification of root counting in which the assumed isolation for a disc $\Delta$ is heuristically verified by applying sufficiently many ETs on the contour of $\Delta$.

For $d \geq 1, r > 0$ and $\theta > 1$, define

$$C(d, r, e, \theta) := \log(L(d, r, e, \theta)) \log_\theta(d/e)$$

and $C(d, r) := C(d, r, 1/4, 2)$.

### 3.1 Root Counting with known isolation

For a disc $\Delta$ which is at least $\theta$-isolated for $\theta > 1$, algo. 2 computes the number $m$ of roots in $\Delta$ as the unique integer in the interval of width $< 1/2$ obtained by approximating 0-th cauchy sum of $p\Delta$ in the unit disc within error $< 1/2$.

**Algorithm 2 CauchyRC1($P, P', \Delta, \theta$)**

**Require:** $P, P'$ evaluation oracles for $p$ and $p'$, s.t. $p$ is monic of degree $d$. $\Delta = D(c, r), \theta \in \mathbb{R}, \theta > 1$.

**Ensure:** An integer $m \in \{-1, 0, \ldots, d\}$.

1: $(success, [s_0]) \leftarrow \text{ApproxShs}(P, P', \Delta, \theta, 0, 1)$
2: if success = false or $s_0$ contains no integer then
3: return $-1$
4: return the unique integer in $s_0$

**Proposition 9** Let $\Delta = D(c, r)$. CauchyRC1($P, P', \Delta, \theta$) requires evaluation of $P$ and $P'$ at $O(C(d, r, 1/4, \theta))$ points and $O(C(d, r, 1/4, \theta))$ arithmetic operations, all with precision less than $L(d, r, 1/4, \theta)$. Let $m$ be the output of the latter call.

(a) If $A(c, \frac{r}{\theta}, r\theta)$ contains no roots of $p$ then $m = \#(\Delta, p)$.

(b) If $m \neq 0$ then $p$ has a root in the disc $\theta\Delta$.

Prop. 9 is a direct consequence of Prop. 8: in each execution of the while loop in ApproxShs($P, P', \Delta, \theta, 0, 1$), $P$ and $P'$ are evaluated at $O(\log(d/e))$ points and the while loop executes an $O(\log(L(d, r, 1, \theta)))$ number of times.

### 3.2 Cauchy Exclusion Test

We follow [6] and increase the chances for obtaining a correct result for the exclusion of a disc with unknown isolation by approximating the first three power sums of $p\Delta$ in $D(0, 1)$ in Algo. 3. One has:

**Proposition 10** Let $\Delta = D(c, r)$. CauchyET($P, P', \Delta$) requires evaluation of $P$ and $P'$ at $O(C(d, r))$ points and $O(C(d, r))$ arithmetic operations, all with precision less than $L(d, r)$. Let $m$ be the output of the latter call.

(a) If $D(c, \frac{4r}{3})$ contains no roots of $p$ then $m = 0$. Let $B$ be a box so that $2B$ contains no root and suppose $\Delta = D(B)$; then $m = 0$.

(b) If $m \neq 0$ then $p$ has a root in the disc $(4/3)\Delta$. 
Algorithm 3 CauchyET(\(P, P', \Delta\))

Require: \(P, P'\) evaluation oracles for \(p\) and \(p'\), s.t. \(p\) is monic of degree \(d\). \(\Delta = D(c, r)\).
Ensure: An integer \(m \in \{-1, 0\}\).

1: \((\text{success}, [s_0, s_1, s_2]) \leftarrow \text{ApproxShs}(P, P', \Delta, 4/3, 2, 1)\)
2: if \(\text{success} = \text{false} \) or \(0 \notin s_0 \) or \(0 \notin s_1 \) or \(0 \notin s_2 \) then
3:   return \(-1\)
4: return \(0\)

3.3 Cauchy Root Counter

We begin with a lemma proved in A.4 and illustrated in Fig. 1.

Lemma 11 Let \(c \in \mathbb{C}\) and \(\rho_-, \rho_+ \in \mathbb{R}\). Define \(\mu = \frac{\rho_+ + \rho_-}{2}, \rho = \frac{\rho_+ - \rho_-}{2}, w = \frac{\mu}{\rho}, v = \lceil 2\pi w \rceil\) and \(c_j = c + \mu e^{j2\pi i}\) for \(j = 0, \ldots, v-1\). Then the re-union of the discs \(D(c_j, (5/4)\rho)\) covers the annulus \(A(c, \rho-, \rho_+)\).

Fig. 1. Illustration for Lem. 11. In red, the inner and outer circles of the annulus covered by the \(v\) discs \(D(c_j, (5/4)\rho)\).

For a disc \(D(c, r)\) and a given \(a > 1\), we follow Lem. 11 and cover the annulus \(A(c, r/a, ra)\) with \(v\) discs of radius \(r \frac{5(a^{-1}/a)}{4\pi^2}\) centered at \(v\) equally spaced points.
of the boundary circle of $D(c, r^{a+1/a})$. Define

$$f(a, \theta) = \frac{1}{2} a(1 - \frac{5}{4} \theta) + \frac{1}{a}(1 + \frac{5}{4} \theta)$$

(13)

and

$$f(a, \theta) = \frac{1}{2} a(1 + \frac{5}{4} \theta) + \frac{1}{a}(1 - \frac{5}{4} \theta),$$

(14)

then the annulus $A(c, r f_-(a, \theta), r f_+(a, \theta))$ covers the $\theta$-inflation of those $v$ discs.

Algorithm 4 counts the number of roots of $p$ in a disc and satisfies:

**Algorithm 4 CauchyRC2($P, P', \Delta, a$)**

**Require:** $P, P'$ evaluation oracles for $p$ and $p'$, s.t. $p$ is monic of degree $d$. $\Delta = D(c, r)$.

$a \in \mathbb{R}, a > 1$.

**Ensure:** An integer $m \in \{-1, 0, \ldots, d\}$.

Verify that $\Delta$ is at least $a$-isolated with CauchyET

1: $\rho_- \leftarrow \frac{1}{a} r$, $\rho_+ = ar$.
2: $\rho \leftarrow \frac{\rho_- + \rho_+}{2}$, $\mu \leftarrow \frac{\rho_- + \rho_+}{2}$, $w \leftarrow \rho$, $v \leftarrow \lfloor 2\pi w \rfloor$, $\zeta \leftarrow \exp(\frac{2\pi i}{v})$.
3: for $i = 0, \ldots, v - 1$ do
4: $c_i \leftarrow c + \mu \zeta^i$
5: if CauchyET($P, P', D(c_i, \frac{\rho}{v})$) returns $-1$ then
6: return $-1$ // $A(c, r f_-(a, \frac{\rho}{v}), r f_+(a, \frac{\rho}{v}))$ contains a root
7: return CauchyRC1($P, P', \Delta, a$)

**Proposition 12** The call CauchyRC2($P, P', \Delta, a$) amounts to $\lceil 2\pi \frac{a^2 + 1}{a^2 - 1} \rceil$ calls to CauchyET and one call to CauchyRC1.

Let $\Delta = D(c, r)$ and $A$ be the annulus $A(c, r f_-(a, \frac{\rho}{v}), r f_+(a, \frac{\rho}{v}))$. Let $m$ be the output of the latter call.

(a) If $A$ contains no root then $m \geq 0$ and $\Delta$ contains $m$ roots.

(b) If $m \neq 0$, then $A$ contains a root.

We state the following corollary.

**Corollary 13** (of Prop. 12) Let $\theta = \frac{4}{3}$ and $a = \frac{11}{10}$. Remark that

$$f_-(a, \theta) = \frac{93}{110} > 2^{-1/4} \text{ and } f_+(a, \theta) = \frac{64}{55}.$$ 

The call CauchyRC2($P, P', \Delta, a$) amounts to $\lceil 2\pi \frac{a^2 + 1}{a^2 - 1} \rceil = 67$ calls to CauchyET, for discs of radius $\frac{31}{176} r \in O(r)$ and one call to CauchyRC1 for $\Delta$. This requires evaluation of $P$ and $P'$ at $O(C(d, r))$ points, and $O(C(d, r))$ arithmetic operations, all with precision less than $L(d, r)$. 

4 Root radii algorithms

4.1 Approximation of the largest root radius

For a monic \( p \) of degree \( d \) and bit-size \( \tau = \log \| p \|_1 \), we describe a naive approach to the approximation of the largest modulus \( r_d \) of a root of \( p \). Recall Cauchy’s bound for such a polynomial: \( r_d \leq 1 + 2^\tau \). The procedure below finds an \( r \) so that \( r_d < r \) and either \( r = 1 \) or \( r/2 < r_d \) when \( p \) is given by the evaluation oracles \( \mathcal{P}, \mathcal{P}' \).

1: \( r \leftarrow 1, \ m \leftarrow -1 \)
2: while \( m \leq d \) do
3: \( m \leftarrow \text{CauchyRC2}(\mathcal{P}, \mathcal{P}', D(0, r), 4/3) \)
4: if \( m < d \) then
5: \( r \leftarrow 2r \)

As a consequence of Prop. 12 each execution of the while loop terminates and the procedure terminates after no more than \( O(\tau) \) execution of the while loop. It requires evaluation of \( \mathcal{P} \) and \( \mathcal{P}' \) at \( O(\tau C(d, r)) \) points and \( O(\tau C(d, r)) \) arithmetic operations all with precision less than \( L(d, r) \). Its correctness is implied by correctness of the results of \texttt{CauchyRC2} which is in turn implied by correctness of the results of \texttt{CauchyET}.

4.2 Approximation of the \((d + 1 - m)\)-th root radius

For a \( c \in \mathbb{C} \) and an integer \( m \geq 1 \), we call \((d + 1 - m)\)-th root radius from \( c \) and write it \( r_m(c, p) \) the smallest radius of a disc centered in \( c \) and containing exactly \( m \) roots of \( p \).

Algo. 5 approximates \( r_m(c, p) \) within the relative error \( \nu \). It is based on the RC \texttt{CauchyRC2} and reduces the width of an initial interval \([l, u]\) containing \( r_m(c, p) \) with a double exponential sieve.

Its correctness for given input parameters is implied by correctness of the results of \texttt{CauchyRC2} which is in turn implied by correctness of the results of \texttt{CauchyET}. Algo. 5 satisfies the proposition below, proved in A.5.

**Proposition 14** The call \( \text{RootRadius}(\mathcal{P}, \mathcal{P}', D(c, r), m, \nu, \varepsilon) \) terminates after \( O(\log \log (r/\varepsilon)) \) iterations of the while loop. Let \( \Delta = D(c, r) \) and \( r' \) be the output of the latter call.

(a) If \( \Delta \) contains at least a root of \( p \) then so does \( D(c, 2r') \).

(b) If \( \Delta \) contains \( m \) roots of \( p \) and \texttt{CauchyRC2} returns a correct result each time it is called in Algo. 5 then either \( r' = \varepsilon \) and \( r_m(c, p) \leq \varepsilon \), or \( r_m(c, p) \leq r' \leq \nu r_m(c, p) \).

5 A compression algorithm

We begin with a geometric lemma illustrated in Fig. 2.
Algorithm 5 RootRadius($\mathcal{P}, \mathcal{P}', \Delta, m, \nu, \varepsilon$)

Require: $\mathcal{P}$, $\mathcal{P}'$ evaluation oracles for $p$ and $p'$, s.t. $p$ is monic of degree $d$. A disc $\Delta = D(c, r)$, an integer $m \geq 1$, $\nu \in \mathbb{R}$, $\nu > 1$, and $\varepsilon \in \mathbb{R}$ such that $0 < \varepsilon \leq r/2$.

Ensure: $r' > 0$

1: choose $a$ s.t. $\nu^{-\frac{1}{4}} < f_-(a, \frac{4}{7}) < f_+(a, \frac{4}{7}) < 2$ \hspace{1em} // when $\nu = 2$ take $a = 11/10$
2: $l \leftarrow 0$, $u \leftarrow r$
3: $m' \leftarrow \text{CauchyRC2}($\mathcal{P}, \mathcal{P}', D(c, \varepsilon), a$)
4: if $m' = m$ then
   5: return $\varepsilon$
   6: else
5: Apply double exponential sieve to get $l \leq r_{d+1-m}(c, p)$
6: while $l < u/\nu$ do
7: $t \leftarrow (lu)^{\frac{1}{2}}$
8: $m' \leftarrow \text{CauchyRC2}($\mathcal{P}, \mathcal{P}', D(c, t), a$)
9: if $m' = m$ then
   10: $u \leftarrow t$
   11: else
   12: $l \leftarrow f_-(a, \frac{4}{7}) t$
   13: end
14: return $u$

Lemma 15 Let $c \in \mathbb{C}$ and $r, \varepsilon, \theta \in \mathbb{R}$ satisfying $0 < \varepsilon \leq r/2$ and $\theta \geq 2$. Let $c' \in D(c, \frac{r}{\varepsilon + \frac{\theta}{2}})$ and $u = \max(|c - c'| + \frac{5}{7}, r)$. Then

$$D\left(c, \frac{r}{\theta}\right) \subseteq D(c', u) \subseteq D\left(c, \frac{7}{4}r\right) \subseteq D(c, r\theta).$$

The following lemma is a direct consequence of Lem. 15 because $s_1(p, c, r)/m$ is the center of gravity of the roots of $p$ in $D(c, r)$.

Lemma 16 Let $D(c, r)$ be at least $\theta \geq 2$-isolated and contain $m$ roots. Let $s_1^\circ$ approximate $s_1(p, c, r)$ such that $|s_1^\circ - s_1(p, c, r)| \leq \frac{\varepsilon r}{m}$ and $\varepsilon \leq \frac{r}{2}$. Then for $c' = \frac{s_1^\circ}{m}$ and $u = \max(|c - c'| + \frac{5}{7}, r)$, the disc $D(c', u)$ contains the same roots of $p$ as $D(c, r)$.

Algo. [6] solves the $\varepsilon$-CRD problem for $\gamma = 1/8$. It satisfies the proposition below proved in [A,6].

Proposition 17 The call Compression($\mathcal{P}, \mathcal{P}', \Delta, \varepsilon$) where $\Delta = D(c, r)$ requires evaluation of $\mathcal{P}$ and $\mathcal{P}'$ at $O\left(C(d, \varepsilon) \left(\frac{d}{\varepsilon \log \frac{\varepsilon}{2}}\right)\right)$ points and the same number of arithmetic operations, all with precision less than $L(d, \varepsilon/4)$. Let $m$, $D(c', r')$ be the output of the latter call.

(a) If $\Delta$ is at least $2$-isolated and $Z(\Delta, p) \neq \emptyset$, and if the call to RootRadius returns a correct result, then $D(c', r')$ is equivalent to $\Delta$, contains $m$ roots of $p$ and satisfies: either $r' \leq \varepsilon$, or $D(c', r')$ is at least $1/8$-rigid.

(b) If $m' > 0$ then $D(c', 2r')$ contains at least a root of $p$. 
Algorithm 6 Compression (\(\mathcal{P}, \mathcal{P}^\prime, \Delta, \varepsilon\))

Require: \(\mathcal{P}, \mathcal{P}^\prime\) evaluation oracles for \(p\) and \(p^\prime\), s.t. \(p\) is monic of degree \(d\). A disc \(\Delta = D(c, r)\), and a strictly positive \(\varepsilon \in \mathbb{R}\).

Ensure: An integer \(m\) and a disc \(D(c^\prime, r^\prime)\).

1: \(\theta \leftarrow 2, \varepsilon^\prime \leftarrow \varepsilon / 2\theta\)
2: \((\text{success}, [s_0, s_1]) \leftarrow \text{ApproxShs}(\mathcal{P}, \mathcal{P}^\prime, \Delta, \theta, 1, \min(\varepsilon^\prime, 1))\)
3: if not success or \(s_0\) does not contain an integer > 0 then
4: \(\text{return } -1, \emptyset\)
5: \(m \leftarrow \) the unique integer in \(s_0\)
6: if \(r/2 < \varepsilon\) then
7: \(\text{return } m, D(c, r/2)\)
8: \(c^\prime \leftarrow c(s_1) / m\) \hspace{1cm} // \(|c^\prime - s_1(p, c, r)/m| < \varepsilon / 4\theta\)
9: if \(m = 1\) then
10: \(m \leftarrow \text{CauchyRC1}(\mathcal{P}, \mathcal{P}^\prime, D(c^\prime, 2\varepsilon^\prime), 2)\)
11: \(\text{return } m, D(c^\prime, 2\varepsilon^\prime)\)
12: \(u \leftarrow \max (|c - c^\prime| + \varepsilon^\prime, r)\)
13: \(r^\prime \leftarrow \text{RootRadius}(\mathcal{P}, \mathcal{P}^\prime, D(c^\prime, u), \frac{1}{3}, m, \theta, \varepsilon / 2)\)
14: \(\text{return } m, D(c^\prime, r^\prime)\)

6 Two Cauchy Root Finders

In order to demonstrate the efficiency of the algorithms presented in this paper, we describe here two experimental subdivision algorithms, named \texttt{CauchyQIR} and \texttt{CauchyComp}, solving the \(\varepsilon\)-CRC problem for oracle polynomials based on our Cauchy ET and RCs. Both algorithms can fail—in the case where \texttt{CauchyET} excludes a box of the subdivision tree containing a root— but account for such a failure. Both algorithm adapt the subdivision process described in [2]. \texttt{CauchyQIR} uses QIR Abbott iterations to ensure fast convergence towards clusters of roots. \texttt{CauchyComp} uses \(\varepsilon\)-compression presented in Sec. 5. In both solvers, the main subdivision loop is followed by a post-processing step to check that the output...
is a solution of the ε-CRC problem. The main subdivision loop does not involve coefficients of input polynomials but use evaluation oracles instead. However, we use coefficients obtained by evaluation-interpolation in the post-processing step in the case where some output discs contain more than one root. We observe no failure of our algorithms in all our experiments covered in Sec. 7.

6.1 Subdivision loop

Let $B_0$ be a box containing all the roots of $p$. Such a box can be obtained by applying the process described in Subsec. 4.1.

Sub-boxes, component and quadrisection For a box $B(a + ib, w)$, let $Children_1(B)$ be the set of the four boxes $\{B((a \pm w/4) \pm i(b \pm w/4), w/2)\}$, and

$$Children_n(B) := \bigcup_{B' \in Children_{n-1}(B)} Children_1(B').$$

A box $B$ is a sub-box of $B_0$ if $B = B_0$ or if there exist an $n \geq 1$ s.t. $B \in Children_n(B_0)$. A component $C$ is a set of connected sub-boxes of $B_0$ of equal widths. The component box $B(C)$ of a component $C$ is the smallest (square) box subject to $C \subseteq B(C) \subseteq B_0$ minimizing both $Re(c(B(C)))$ and $Im(c(B(C)))$. We write $D(C)$ for $D(B(C))$. If $S$ is a set of components (resp. discs) and $\delta > 0$, write $\delta S$ for the set $\{\delta D(A) \text{ (resp. } A) \mid A \in S\}$.

Definition 18 Let $Q$ be a set of components or discs. We say that a component $C$ (resp. a disk $\Delta$) is $\gamma$-separated (or $\gamma$-sep.) from $Q$ when $\gamma D(C)$ (resp. $\gamma \Delta$) has empty intersection with all elements in $Q$.

Remark 19 Let $Q$ be a set of components and $C \notin Q$ a component. If $Z(C, p) = Z(\{C\} \cup Q, p)$ and $C$ is 4-separated from $Q$ then $2D(C)$ is at least 2-isolated.

Subdivision process We describe in Algo. 7 a subdivision algorithm solving the ε-CRC problem. The components in the working queue $Q$ are sorted by decreasing radii of their containing discs. It is parameterized by the flag compression indicating whether compression or QIR Abbott iterations have to be used. In QIR Abbott iterations of Algo. 7 in [3], we replace the Graeffe Pellet test for counting roots in a disc $\Delta$ by CauchyRC2($\mathcal{P}$, $\mathcal{P}'$, $\Delta$, 4/3). If a QIR Abbott iteration in step 12 fails for input $\Delta, m$, it returns $\Delta$. Steps 20-21 prevent $C$ to artificially inflate when a compression or a QIR Abbott iteration step does not decrease $D(C)$. For a component $C$, $Quadrisect(C)$ is the set of components obtained by grouping the set of boxes

$$\bigcup_{B \in C} \{B' \in Children_1(B) \mid \text{CauchyET}($$ \mathcal{P}$, $\mathcal{P}'$, $D(B')$) = -1\}$$

into components.

The while loop in steps 4-22 terminates because all our algorithms terminate, and as a consequence of (a) in Prop. 9 any component will eventually be decreased until the radius of its containing disc reaches $\varepsilon/2$. 
Algorithm 7 CauchyRootFinder($P, P', \varepsilon, compression$)

Require: $P$ and $P'$ evaluation oracles for $p$ and $p'$, s.t. $p$ is monic of degree $d$. A (strictly) positive $\varepsilon \in \mathbb{R}$, a flag $compression \in \{true, false\}$.

Ensure: A flag $success$ and a list $R = \{(\Delta^1, m^1), \ldots, (\Delta^\ell, m^\ell)\}$

1: $B_0 \leftarrow$ box s.t. $\#(B,p) = d$ as described in Subsec. 4.1
2: $Q \leftarrow \{B_0\}$ // $Q$ is a queue of components
3: $R \leftarrow \{\}$ // $R$ is the empty list of results
4: while $Q$ is not empty do
5: $C \leftarrow pop(Q)$
6: if $C$ is 4-separated from $Q$ then
7: if $compression$ then
8: $m, D(c,r) \leftarrow Compression(P, P', 2D(C), \varepsilon/2)$
9: else
10: $m \leftarrow CauchyRC1(P, P', 2D(C), 2)$
11: if $m > 0$ then
12: $D(c,r) \leftarrow$ QIR Abbott iteration for $D(C), m$
13: if $m \leq 0$ then
14: return $fail, \emptyset$
15: if $r \leq \varepsilon/2$ and $D(c,2r)$ is 3-sep. from $2Q$ and is 1-sep. from $6Q$ then
16: push($R, (D(c,2r), m)$)
17: continue
18: else
19: $C' \leftarrow$ component containing $D(c,r)$
20: if $C' \subset C$ then
21: $C \leftarrow C'$
22: push($Q, Quadrisect(C)$)
23: $success \leftarrow verify(R$ as described in 6.2)
24: return $success, R$

6.2 Output verification

After the subdivision process described in steps 1-22 of Algo. 7, $R$ is a set of pairs of the form \{$(\Delta^1, m^1), \ldots, (\Delta^\ell, m^\ell)$\} satisfying, for any $1 \leq j \leq \ell$:

- $\Delta^j$ is a disc of radii $\leq \varepsilon$, $m^j$ is an integer $\geq 1$,
- $\Delta^j$ contains at least a root of $p$,
- for any $1 \leq j' \leq \ell$ s.t. $j' \neq j$, $3\Delta^j \cap \Delta^{j'} = \emptyset$.

The second property follows from (b) of Prop. 10 and (b) of Prop. 17 when compression is used. Otherwise, remark that a disk $\Delta$ in the output of QIR Abbott iteration in step 12 of Algo. 7 verifies CauchyRC2($P, P', \Delta, 4/3 > 0$ and apply (b) of Prop. 12. The third property follows from the if statement in step 15 of Algo. 7 Decompose $R$ as the disjoint union $R_1 \cup R_{>1}$ where $R_1$ is the subset of pairs $(\Delta^j, m^j)$ of $R$ where $m^j = 1$ and $R_{>1}$ is the subset of pairs $(\Delta^j, m^j)$ of $R$ where $m^j > 1$, and make the following remark:
Remark 20 If \( m^1 + \ldots + m^\ell = d \) and for any \((\Delta^i, m^i) \in R_{\geq 1}\), \( \Delta^i \) contains exactly \( m^i \) roots of \( p \), then \( R \) is a correct output for the \( \varepsilon \)-CRC problem with input \( p \) of degree \( d \) and \( \varepsilon \).

According to Rem. 20 checking that \( R \) is a correct output for the \( \varepsilon \)-CRC problem for fixed input \( p \) of degree \( d \) and \( \varepsilon \) amount to check that the \( m^i \)'s add up to \( d \) and that for any \( \Delta^i \in R_{>1} \), \( \Delta^i \) contains exactly \( m^i \) roots of \( p \). For this last task, we use evaluation-interpolation to approximate the coefficients of \( p \) and then apply the Graeffe-Pellet test of \cite{2}.

7 Experiments

We implemented Algo. 7 in the C library Ccluster. Call \( \text{CauchyComp} \) (resp. \( \text{CauchyQIR} \)) the implementation of Algo. 7 with \( \text{compression} = \text{true} \) (resp. \( \text{false} \)). In the experiments we conducted so far, \( \text{CauchyComp} \) and \( \text{CauchyQIR} \) never failed.

Test suite We experimented \( \text{CauchyComp} \), \( \text{CauchyQIR} \) and \( \text{MPsolve} \) on Mandelbrot and Mignotte polynomials as defined in Sec. 1 as well as Runnel and random sparse polynomials. Let \( r = 2 \). The Runnel polynomial is defined inductively as

\[
\text{Run}_0(z) = 1, \quad \text{Run}_1(z) = z, \quad \text{Run}_{k+1}(z) = \text{Run}_k(z)^r + rz \text{Run}_{k-1}(z)^r^2
\]

It has real coefficients, a multiple root (zero), and can be evaluated fast. We generate random sparse polynomials of degree \( d \), bitsize \( \tau \) and \( \ell \geq 2 \) non-zero terms as follows, where \( p_i \) stands for the coefficient of the monomial of degree \( i \) in \( p \): \( p_0 \) and \( p_d \) are randomly chosen in \([-2r^{-1}, 2r^{-1}]\), then \( \ell - 2 \) integers \( i_1, \ldots, i_{\ell-1} \) are randomly chosen in \([1, d-1]\) and \( p_{i_1}, \ldots, p_{i_{\ell-1}} \) are randomly chosen in \([-2r^{-1}, 2r^{-1}]\). The other coefficients are set to 0.

Results We report in tab. 1 results of those experiments for Mandelbrot and Mignotte polynomials with increasing degrees and increasing values of \( \log_{10}(\varepsilon - 1) \). We account for the running time \( t \) for the three above-mentioned solvers. For \( \text{CauchyQIR} \) (resp. \( \text{CauchyComp} \)), we also give the number \( n \) of exclusion tests in the subdivision process, and the time \( t_N \) (resp. \( t_C \)) spent in QIR Abbott iterations (resp. compression).

Our compression algorithm allows smaller running times for low values of \( \log_{10}(\varepsilon - 1) \) because it compresses a component \( C \) on the cluster it contains as of \( 2D(C) \) is 2-isolated, whereas QIR Abbott iterations require the radius \( \Delta \) to be near the radius of convergence of the cluster for Schröder’s iterations.

We report in tab. 2 the results of runs of \( \text{CauchyComp} \) and \( \text{MPsolve} \) for polynomials of our test suite of increasing degree, for \( \log_{10}(\varepsilon - 1) = 16 \). For random sparse polynomials, we report averages over 10 examples. The column \( t_V \) accounts for the time spent in the verification of the output of \( \text{CauchyComp} \) (see 6.2), it is 0 when all the pairs \((\Delta^i, m^i)\) in the output verify \( m^i = 1 \). It is \( > 0 \) when there is at least a pair with \( m^i > 1 \).

The maximum precision \( L \) required in all our tests was 106, which makes us believe that our analysis in Prop. 8 is very pessimistic. Our experimental solver \( \text{CauchyComp} \) is faster than \( \text{MPsolve} \) for polynomials that can be evaluated fast.
### Table 2. Runs of CauchyComp and MPsolve on polynomials of our test suite for $\log_{10}(\varepsilon^{-1}) = 16$.

### 8 Conclusion

We presented, analyzed and verified practical efficiency of two basic subroutines for solving the complex root clustering problem for black box polynomials. One is a root counter, the other one is a compression algorithm. Both algorithms are well-known tools used in subdivision procedures for root finding.

We propose our compression algorithm not as a replacement of QIR Abbott iterations, but rather as a complementary tool: in future work, we plan to use compression to obtain a disc where Schröder’s/QIR Abbott iterations would converge fast.

The subroutines presented in this paper laid down the path toward a Cauchy Root Finder, that is, an algorithm solving the $\varepsilon$-CRC problem for black box polynomials.

A Proofs

A.1 Proof of Lem. 3

Let $\Delta = D(c, r)$ contain $d_\Delta$ roots. Suppose that the roots $\alpha_1, \ldots, \alpha_d$ of $p$ are indexed such that $\alpha_1, \ldots, \alpha_{d_\Delta}$ are in $\Delta$ and $\alpha_{d_\Delta+1}, \ldots, \alpha_d$ are outside $\Delta$. Since $\Delta$ has isolation $\theta$, it follows that

$$|c + rz^g - \alpha_i| \geq r - \frac{r(\theta - 1)}{\theta} \text{ when } i \leq d_\Delta, \text{ and}$$

$$\geq \theta r - r = r(\theta - 1) \text{ when } i \geq d_\Delta + 1$$

(15)

(16)

Write

$$p(c + rz^g) = \text{lcf} \left( p \right) \prod_{i=1}^{d_\Delta} (c + rz^g - \alpha_i) \prod_{i=d_\Delta+1}^{d} (c + rz^g - \alpha_i)$$

and deduce the first inequality of Lem. 3. Then write

$$\frac{p'(c + rz^g)}{p(c + rz^g)} = \sum_{i=1}^{d_\Delta} \frac{1}{c + rz^g - \alpha_i} + \sum_{i=d_\Delta+1}^{d} \frac{1}{c + rz^g - \alpha_i}$$

and deduce the second inequality of Lem. 3.

\[\Box\]

A.2 Proof of Lem. 7

Lem. 7 is a direct consequence of the following Lemma:

Lemma 21 Let $D(c, r)$ be a complex disc, $\theta > 1$, $e > 0$ and

$$a = \max \left( \frac{\theta}{r(\theta - 1)}, 1 \right) \text{ and } \omega = \min \left( \frac{e}{26rda^{q+1}}, 1 \right).$$

Let $0 \leq h < q$ be integers and $\zeta$ be a primitive $q$-th root of unity. For $0 \leq g \leq q - 1$, write $\psi^g = c + rz^g$ and suppose that

$$|p(\psi^g)| \geq \frac{1}{2} \left( \frac{r(\theta - 1)}{\theta} \right)^d \text{ and } \left| \frac{p'(\psi^g)}{p(\psi^g)} \right| \leq 2 \left( \frac{dd\theta}{r(\theta - 1)} \right).$$

For $0 \leq g \leq q - 1$ and $0 \leq h < q$ write:

$$\zeta^g h + 1 = \zeta^g (h + 1) + \delta z^g (h + 1),$$

$$p(\psi^g) = p(\psi^g) + \delta p(\psi^g) \text{ and } p'(\psi^g) = p'(\psi^g) + \delta p'(\psi^g).$$

Let

$$s_h^* = \sum_{g=0}^{q-1} \zeta^g (h + 1) \frac{p'(\psi^g)}{p(\psi^g)} \text{ and } s_h^* = s_h^* (p, c, r).$$

If $|\delta z^g (h + 1)| \leq \omega$, $|\delta p(\psi^g)| \leq \omega$ and $|\delta p'(\psi^g)| \leq \omega$ for all $0 \leq g \leq q - 1$ and $0 \leq h < q$ then

$$|s_h^* - s_h^*| \leq e.$$
Proof of Lem 21: We depart from the inequality:
\[
\left| \frac{x}{y} - \frac{x + \delta_x}{y + \delta_y} \right| \leq \frac{|x\delta_y| + |y\delta_x|}{|y||y - \omega|} \leq \left( \frac{|x| + 1}{|y|} + 1 \right) \omega \left| \frac{y}{y - \omega} \right|
\]
valid for $|\delta_x| \leq \omega$, and $|\delta_y| \leq \omega \leq \frac{1}{3}|y|$. Substitute $x = p'(\psi^g)$ and $y = p(\psi^g)$ to obtain:
\[
\left| \frac{p'(\psi^g)}{p(\psi^g)} - \frac{p'(\psi^g)}{p(\psi^g)} \right| \leq 4(2da + 1)a^d \omega
\]
\[
\leq 12da^{d+1} \omega \text{ since } a \geq 1.
\]
Apply inequality $|xy - (x + \delta_x)(y + \delta_y)| \leq |x\delta_y| + |y\delta_x| + |\delta_x\delta_y|$ to obtain
\[
\left| \zeta^g h + 1 \frac{p'(\psi^g)}{p(\psi^g)} - \zeta^g h + 1 \frac{p'(\psi^g)}{p(\psi^g)} \right| \leq 12da^{d+1} \omega + \left| \frac{p'(\psi^g)}{p(\psi^g)} \right| \omega + 12da^{d+1} \omega^2
\]
\[
\leq 12da^{d+1} \omega + 2da \omega + 12da^{d+1} \omega^2
\]
\[
\leq 26da^{d+1} \omega \text{ since } \omega \leq 1.
\]
and apply inequality $|x + y - ((x + \delta_x) + (y + \delta_y))| \leq |\delta_x| + |\delta_y|$ to get
\[
|s_h^* - \tilde{s}_h^*| \leq 26da^{d+1} \omega = e.
\]
\[\square\]

A.3 Proof of Prop. 8

Suppose first that there is a $g$ so that $|p(c + r\zeta^g)| < \ell$. The precision $L$ is increased by the while loop until either $|E_p(c + r\zeta^g, L)| < \ell$ or $\frac{\ell}{2} \in |E_p(c + r\zeta^g, L)|$, which holds for an $L \in O\left(\log 1/\ell\right) = O\left(d\left(\log \frac{a}{\frac{1}{2} - \frac{d}{2}} + \log \frac{1}{\ell}\right)\right)$.

Similarly, suppose that there is a $g$ so that $|p'(c + r\zeta^g)| > \ell'$. The precision $L$ is increased by the while loop until either $p'(c + r\zeta^g, L) > \ell'$ or $2\ell' \in |p'(c + r\zeta^g, L)|$, which holds for an $L \in O\left(\log 1/\ell'\right) = O\left(\log \frac{d}{\frac{1}{2} - \frac{d}{2}} + \log \frac{1}{\ell'}\right)$. 

Thus Algo. \ref{alg:main} either terminates with success = false for an
\[ L \in O \left( \max \left( d \left( \log \frac{\theta}{\theta - 1} + \log \frac{1}{r^d} \right), \log \frac{\theta}{\theta - 1} \right) \right) \]
or enters the for loop with \(|\mathcal{P}(c + r\zeta^d, L)| > \frac{\ell}{2}\) and \(|\mathcal{P}'(c + r\zeta^d, L)| < 2\ell'\) for all \(g\).

Then by Lem. \ref{lem:termination} Algo. \ref{alg:main} terminates for \(L \in O \left( d \left( \log \frac{1}{r^d} + \log \frac{\theta}{\theta - 1} \right) \right)\).

(a) is a consequence of Lem. \ref{lem:termination} and eq. (4) of Thm. \ref{thm:termination}.

(b) If \(D(c, r\theta)\) contains no root of \(p\) then (a) holds and for all \(i \in \{0, \ldots, h\}\), \(s_i(p_\Delta, 0, 1) = 0\).

(c) If \(D(c, r\theta)\) contains no root of \(p\) then (a) holds and \(s_0(p, c, r) = s_0(p_\Delta, 0, 1) = \#(\Delta, p)\).

(d) success = false iff for a \(g\) it holds that \(|\mathcal{P}(c + r\zeta^d, L)| < \ell\) or \(|\mathcal{P}'(c + r\zeta^d, L)| > \ell'\) and so \(|p(c + r\zeta^d)| < \ell\) or \(\frac{|p(c + r\zeta^d)|}{|p(c + r\zeta^d)|} > \ell'\) and \(A(c, r/\theta, r\theta)\) contains at least a root of \(p\).

(e) Suppose that \(A(c, r/\theta, r\theta)\) contains no root of \(p\) (otherwise the proposition is proved). Then \(s_i(p_\Delta, 0, 1) \in \mathbb{N}\) and \(s_i(p_\Delta, 0, 1) \neq 0\). Now if \(\Delta\) contains no root of \(p\) then \(D(0, 1)\) contains no root of \(p\) and \(s_i(p_\Delta, 0, 1) = 0\), which is a contradiction.  \(\square\)

### A.4 Proof of Lemma \ref{lem:subdivision}

See Fig. \ref{fig:subdivision} for an illustration. Let \(c_{j, j+1}\) be the middle of \(c_j, c_{j+1}\) and \(z_j, z_j'\) be the intersections of the two circles \(C(c_j, a\rho), C(c_{j+1}, a\rho)\) with \(a > 1\), such that \(|c - z_j| < |c - z_j'|\). Let \(x\) be the distance \(|c_{j, j+1} - c_{j+1}|\); one has
\[ x = |c_{j, j+1} - c_{j+1}| = \mu \sin(\pi/v) \leq \rho/2. \tag{17} \]

Let \(y\) be the distance \(|c_{j, j+1} - z_j|\); one has
\[ y = \sqrt{(a\rho)^2 - (\mu \sin(\pi/v))^2} \geq \rho\sqrt{a^2 - 1/4}. \tag{18} \]

where the inequality follows from Eq. \ref{eq:subdivision}. Finally,
\[ |c_{j, j+1} - c| = \mu \cos(\pi/v) \geq \mu \cos(1/2w). \tag{19} \]

One has to show:
\[ \mu \cos(\pi/v) - y \leq \mu - \rho \tag{20} \]
\[ \mu \cos(\pi/v) + y \geq \mu + \rho \tag{21} \]

Eq. \ref{eq:subdivision} is straightforward when \(y \geq \rho\), which is the case when \(a = 5/4\). According to inequalities \ref{eq:subdivision} and \ref{eq:subdivision}, Eq. \ref{eq:subdivision} holds if
\[ \mu \cos(1/2w) + \rho\sqrt{a^2 - 1/4} \geq \mu + \rho \]
which rewrites
\[ a \geq \sqrt{w(1 - \cos(1/(2w))) + 1}^2 + 1/4. \]

The right-hand side of the latter inequality is decreasing with \( w \) when \( w \geq 1 \), and is less that \( 5/4 \) for any \( w \geq 1 \). \( \Box \)

### A.5 Proof of Prop. 14

Each call to \texttt{CauchyRC2} in Algo. 5 terminates as a consequence of Prop. 8. Suppose that Algo. 5 enters the while loop with

\[ l < \frac{u}{\nu}, \text{i.e. } \frac{u}{T} > \nu. \]

From the choice of \( a \) in step 1, \( f_-(a, \theta) > \nu^{-1/4} \) and one has

\[ \frac{1}{f_-(a, \theta)} < \nu^{1/4} < \left( \frac{u}{T} \right)^{1/4}. \]

Let \( l', u' \) be the new values for \( l, u \) after one iteration of the \texttt{while} loop; in the worst case (step 14) one has

\[ \frac{u'}{T'} = \frac{u}{f_-(a, \theta)(lu)^{1/2}} = \left( \frac{u}{T} \right)^{1/2} \frac{1}{f_-(a, \theta)} < \left( \frac{u}{T} \right)^{1/2} \left( \frac{u}{T} \right)^{1/4} < \left( \frac{u}{T} \right)^{3/4}. \]

As a consequence the \texttt{while} loop decreases the value \( \log_2 \left( \frac{u}{T} \right) \) by at least \( \frac{4}{3} \) every each recursive application as long as

\[ \frac{u}{T} > \nu \Leftrightarrow \log_2 u - \log_2 l - \log_2 \nu > 0 \]

and so it stops in at most

\[ \lceil \log_2 \left( \log_2 u - \log_2 l - \log_2 \nu \right) \rceil \in O(\log \log(r/\varepsilon)) \]

steps.

Next, suppose that \texttt{RootRadius}(\( \mathcal{P}, \mathcal{P}', \Delta, \nu, \varepsilon \)) return \( r' \).

To prove (b), suppose that \( \Delta \) contains \( m \) roots of \( p \) and \texttt{CauchyRC2} returns a correct result each time it is called in Algo. 5.

Suppose first that the call \texttt{CauchyRC2} in step 3 returns \( m' = m \); then \( r' = \varepsilon \) and \( D(c, r') \) contains \( m \) roots thus \( r_m(c, p) \leq \varepsilon \).

Suppose now that the call \texttt{CauchyRC2} in step 3 returns \( m' \neq m \). If \( m \neq 0 \), from Prop. 12 then \( A(c, \varepsilon f_-(a, \frac{1}{3}), \varepsilon f_+(a, \frac{1}{3})) \) contains a root. Since \( \varepsilon f_+(a, \frac{1}{3}) < 2\varepsilon \leq r \) (from the choice of \( a \) in step 1) and \( \Delta = D(c, r) \) contains \( m \) roots, \( r_m(c, p) = f_-(a, \frac{1}{3}) \varepsilon \).

Finally, if the call \texttt{CauchyRC2} in step 3 returns \( m' = 0 \) then \( D(c, \varepsilon) \) contains no roots and \( r_m(c, p) = \varepsilon > f_-(a, \frac{1}{3}) \varepsilon \).

Thus if Algo. 5 enters the while loop, it does so for \( l \) and \( u \) satisfying \( l \leq r_m(c, p) \leq u \). Apply the same reasoning to show that this property is preserved by the while loop, and when it terminates, \( r_m(c, p) \leq r' \leq \nu r_m(c, p) \).
Let us finally prove (a). Suppose that $\Delta$ contains at least a root of $p$, and let $r_1(c, p)$ be the smallest distance of a root of $p$ to $c$.

Any call \textbf{CauchyRC2}($\mathcal{P}, \mathcal{P}', D(c, t), a$) in Algo. 5 with $t \leq (1/a)r_1(c, p)$ will necessarily return 0 as a consequence of Prop. 12 and $r'$ will necessarily be greater than $(1/a)r_1(c, p)$. Remark that the parameter $a$ chosen in step 1 is less than 2 and complete the proof. \hfill \Box

\textbf{A.6 Proof of Prop. 17}

Let $\theta = 2$. To prove (a), suppose that $\Delta$ is at least $\theta$-isolated. Since $\min(|\varepsilon', 1|) \leq 1$ one can apply (c) of Prop. 8 and after step 2 of Algo. 6 \textit{success} is true and $s_0$ contains the unique integer $m$ equal to the number of root of $p$ in $\Delta$. As a consequence of (a) of Prop. 8 $s_1$ satisfies $|c(s_1) - s_1(p, c, r)| < \varepsilon'/2$ and since $m \geq 1$, $|c(s_1) - s_1(p, c, r)| < m\varepsilon/4\theta$.

If Algo. 6 enters step 6, $D(c, r/2)$ contains $m$ roots and has radius less that $\varepsilon$.

Otherwise, $\varepsilon'$ defined in step 8 satisfies $|\varepsilon' - s_1(p, c, r)/m| < \varepsilon'/4\theta$. When $m = 1$, the unique root of $p$ in $\Delta$ is $s_1(p, c, r)/m$, thus $D(\varepsilon', \varepsilon')$ contains this root.

Suppose now $m \geq 2$; from Lem. 16 the disc $D(\varepsilon', u)$ where

$$u = \max \left(\left|c - \varepsilon'\right| + \frac{r}{\theta}\right)$$

contains the same $m$ roots of $p$ as $\Delta$. Also, $\varepsilon/\theta \leq u/2$ as required in Algo. 5 for \textbf{RootRadius}. In step 13, \textbf{RootRadius}($\mathcal{P}, \mathcal{P}', D(\varepsilon', u), \frac{u}{2}, m, \theta, \varepsilon/\theta$) returns an $r'$ with either $r' = \varepsilon/\theta$ and $r_m(\varepsilon', p) \leq \varepsilon/\theta$, or $r_m(\varepsilon', p) \leq r' < \theta r_m(\varepsilon', p)$.

If $r' = \varepsilon/\theta$, then $D(\varepsilon', r')$ contains the same $m$ roots of $p$ as $\Delta$.

Otherwise, $r' \geq \varepsilon/\theta$, we prove that $D(\varepsilon', r')$ is at least $1/8$-rigid.

$m \geq 2$, and $s_1(p, c, r)/m$ is the center of gravity of the $m$ roots of $p$ in $\Delta$. The distance from $s_1(p, c, r)/m$ to any root of $p$ in $\Delta$ is maximized when one root, say $\alpha$, has multiplicity $m - 1$, and the other one, say $\alpha'$, has multiplicity 1. In this case, $|s_1(p, c, r)/m - \alpha| \leq |s_1(p, c, r)/m - \alpha'| = |\alpha - \alpha'|$. Generally speaking, one has

$$r_m(s_1(p, c, r)/m, p) \leq \frac{m - 1}{m} \max_{\alpha, \alpha' \in \mathcal{Z}(\Delta, p)} |\alpha - \alpha'|.$$
Since $r' > \varepsilon / 2$, $r' - \varepsilon / 4 \geq r'/2$ and
\[
\max_{\alpha, \alpha' \in \mathcal{Z}(\Delta, p)} \frac{|\alpha - \alpha'|}{2r'} \geq \frac{m}{(m - 1) \times \theta \times 4} \geq \frac{1}{8}.
\]

We now prove $(b)$: suppose Algo. 6 enters step 7: if $m > 0$, $D(c, r)$ contains at least a root as a consequence of $(e)$ of Prop. 8. Suppose Algo. 6 enters step 11: $D(c, r)$ contains at least a root as a consequence of $(e)$ of Prop. 8. Otherwise, $(b)$ is a consequence of $(a)$ of Prop. 14.

We finally prove the computational cost. When $r/2 \geq \varepsilon$, the call
\[
\text{ApproxShs}(\mathcal{P}, \mathcal{P}', \Delta, 2, 1, \min(\varepsilon / 4, 1))
\]
in step 2 requires evaluation of $\mathcal{P}$ and $\mathcal{P}'$ at $O(C(d, r, \varepsilon))$ points and the same number of arithmetic operations, all with precision less than $L(d, r, \varepsilon)$. In step 12, $u \in O(r)$ (see Lem. 15), thus the call
\[
\text{RootRadius}(\mathcal{P}, \mathcal{P}', D(c', u), \frac{4}{3}, m, \theta, \varepsilon / 2)
\]
amounts to
\[
O\left(\log \log \frac{r}{\varepsilon}\right)
\]
calls \text{CauchyRC2}(\mathcal{P}, \mathcal{P}', D(c, t), a) with $a = 11/10$ and $t \geq \varepsilon / 2$. From Cor. 13 this amounts to evaluation of $\mathcal{P}$ and $\mathcal{P}'$ at
\[
O\left(C(d, \varepsilon) \log \log \frac{r}{\varepsilon}\right)
\]
points and the same number of arithmetic operations, all with precision less than $L(d, \varepsilon)$. \qed
