Abstract

Recently, researchers observed that gradient descent for deep neural networks operates in an “edge-of-stability” (EoS) regime: the sharpness (maximum eigenvalue of the Hessian) is often larger than stability threshold $2/\eta$ (where $\eta$ is the step size). Despite this, the loss oscillates and converges in the long run, and the sharpness at the end is just slightly below $2/\eta$. While many other well-understood nonconvex objectives such as matrix factorization or two-layer networks can also converge despite large sharpness, there is often a larger gap between sharpness of the endpoint and $2/\eta$. In this paper, we study EoS phenomenon by constructing a simple function that has the same behavior. We give rigorous analysis for its training dynamics in a large local region and explain why the final converging point has sharpness close to $2/\eta$. Globally we observe that the training dynamics for our example has an interesting bifurcating behavior, which was also observed in the training of neural nets.

1 Introduction

Many works tried to understand how simple gradient-based methods can optimize complicated neural network objectives. However, recently some empirical observations show that optimization for deep neural networks may operate in a more surprising regime. In particular, Cohen et al. (2021) observed that when running gradient descent on neural networks with a fixed step-size $\eta$, the sharpness (largest eigenvalue of the Hessian) of the training trajectory often oscillate around the stability threshold $2/\eta$, while the loss still continues to decrease in the long run. This phenomenon is called “edge-of-stability” and has received a lot of attentions.

While many works try to understand why (variants of) gradient descent can still converge despite that the sharpness is larger than $2/\eta$, empirically gradient descent for deep neural networks has even stronger properties. As shown in Fig. 1a, for a fixed initialization, if one changes the step size $\eta$, the final converging point has sharpness very close to $2/\eta$. We call this phenomenon “sharpness adaptivity”. Another perspective on the same phenomenon is that for a wide range of initializations, for a fixed step-size $\eta$ their final converging points all have sharpness very close to $2/\eta$, we call this phenomenon “sharpness concentration”.

Surprisingly, both sharpness adaptivity and sharpness concentration happen on deeper networks, while for shallower models of non-convex optimization such as matrix factorization or 2-layer neural networks the gap between sharpness and $2/\eta$ is often much larger (see Fig. 1b). This suggests that these phenomena are related to the network depth. What is the mechanism for sharpness adaptivity and concentration, and how does that relate to number of layers? To answer these questions, in this paper we consider a minimalist example for edge-of-stability.

*Equal Contribution.

The value $2/\eta$ is called the stability threshold, because if the objective has a fixed Hessian, the trajectory will become unstable if the largest eigenvalue of the Hessian is larger than $2/\eta$. 
More specifically, we construct an objective function (4-layer scalar network), such that gradient descent on this objective has similar empirical behavior as deeper networks. We give a rigorous analysis for the training dynamics of this objective function in a large local region, which proves that the dynamics satisfy both sharpness adaptivity and sharpness concentration. The global training dynamics for our objective exhibits a complicated fractal behavior (which is also why our rigorous results are local), and such behavior has been observed in training of neural networks.

Figure 1: EoS Phenomena in NN Training. We consider three models including a 5-layer ReLU activated fully connected network, a 2-layer fully connected linear network with asymmetric initialization factor (4,0.1) (see Appendix A.1 for explanation), and a 4-layer scalar network equivalent to \[\min_{x,y,z,w} \frac{1}{2} (1 - xyzw)^2.\] For each model we run gradient descent from the same initialization using different learning rates. For (a) and (c), the sharpness converges very close to \(2/\eta\) with loss continuing to decrease. For (b), the sharpness decreases to be significantly lower than \(2/\eta\).

1.1 Our Results

The objective function we consider is very simple: \[\mathcal{L}(x, y, z, w) \triangleq \frac{1}{2} (1 - xyzw)^2.\] One can view this as a 4-layer scalar network (each layer has a single neuron). We even couple the initialization so that \(x = z, y = w\) so effectively it becomes a function on two variables. For this objective function we prove its convergence and sharpness concentration properties:

**Theorem 1.1** (Sharpness Concentration, Informal). For any learning rate \(\eta\) smaller than some constant, there is a constant size region \(S\) such that the GD trajectory with step size \(\eta\) from all initializations in \(S\) converges to a global minimum with sharpness within \((2/\eta - \frac{\eta}{4}, 2/\eta)\).

As a direct corollary we can also prove that it has the sharpness adaptivity property.

**Corollary 1.1** (Sharpness Adaptivity, Informal). There exists a constant size region \(S\) and a corresponding range of step sizes \(K\) that for all \(\eta \in K\), the GD trajectory with step size \(\eta\) from any initialization in \(S\) converges to a global minimum with sharpness within \((2/\eta - \frac{\eta}{4}, 2/\eta)\).

The training dynamics is illustrated in Fig. 2. To analyze the training dynamics, we reparametrize the objective function and show that the 2-step dynamics of gradient descent roughly follows a parabola trajectory. The extreme point of this parabola is the final converging point which has sharpness very close to \(2/\eta\). Intuitively, the parabola trajectory comes from a cubic term in the approximation of the training dynamics (see Section 3.1 for detailed discussions). We can also extend our result to a setting where \(x, y\) are replaced by vectors, see Theorem 3.2 in Section 3.3.

In Section 4 we explain the difference between the dynamics of our degree-4 model with degree-2 models (which are more similar to matrix factorizations or 2-layer neural networks). We show that the dynamics for degree-2 models do not have the higher order terms, and their trajectories form an ellipse instead of a parabola. We also show that degree-3 models have mixed behaviors between degree-2 and degree 4.
Finally, in Section 5 we show why it is difficult to extend Theorem 3.1 to global convergence – the training trajectory exhibits fractal behavior globally. Such behaviors can be qualitatively approximated by simple low-degree nonlinear dynamics that are standard in chaos theory, but are still very difficult to analyze.

1.2 Related Works

The phenomenon of gradient descent on Edge of Stability (EoS) was first formalized and empirically demonstrated in Cohen et al. (2021). They show that the loss can non-monotonically decrease even when the sharpness $\lambda > 2/\eta$. The non-monotone property of the loss has also been observed in many other settings (Jastrzebski et al., 2020; Xing et al., 2018; Lewkowycz et al., 2020; Wang et al., 2022; Arora et al., 2018; Li et al., 2022a).

Recently several works try to understand the mechanism behind EoS with different loss functions under various assumptions (Ahn et al., 2022; Ma et al., 2022; Arora et al., 2022; Lyu et al., 2022; Li et al., 2022b). Ahn et al. (2022) studied the non-monotonic decreasing behavior of gradient descent (which they call unstable convergence), and discussed the possible causes of this phenomenon. From a landscape perspective, Ma et al. (2022) defined a special subquadratic property of the loss function, and proved that EoS occurs based on this assumption.

Arora et al. (2022) and Lyu et al. (2022) studied the implicit bias on the sharpness of gradient descent in some general loss function. Both works focus on the on the regime where the parameter is close to the manifold of minimum loss. Arora et al. (2022) theoretically proved that with a modified loss $\sqrt{L}$ or using normalized GD, gradient descent enters EoS regime and has sharpness reduction effect around the manifold of minima. Lyu et al. (2022) considered the spherical sharpness as the surrogate of the sharpness due to the scale-invariant property. In both works, the effective step-size $\eta$ changes throughout the training process, so sharpness adaptivity and concentration do not apply.

Another line of works (Lewkowycz et al., 2020; Wang et al., 2022) focus on the implicit bias introduced by large learning rate. Lewkowycz et al. (2020) first proposed “catapult phase”, a regime similar to the EoS, where loss does not diverge even if sharpness is larger than $2/\eta$. Wang et al. (2022) theoretically gives a convergence analysis on the matrix factorization problem for large learning rate beyond $2/\lambda$ where $\lambda$ is the sharpness. Their results include two stages; in the first stage the loss may oscillate but never diverge, and the sharpness decreases to enter the second stage where the loss can decrease monotonically. Recently Li et al. (2022b) followed Lewkowycz et al. (2020) and provided a more detailed theoretical analysis on the sharpness along the gradient descent trajectory in an over-parameterized two-layer linear network setting under some assumptions during the training process. They also provided some heuristic explanation on EoS in more general models: gradient descent leaves and re-enters the regime where sharpness $\lambda > 2/\eta$ repeatedly. These works mostly focus on the degree-2 setting which does not have the sharpness adaptivity and sharpness concentration properties.

2 Preliminaries and Notations

In this section, we introduce the simple model exhibiting both sharpness adaptivity and sharpness concentration.

2.1 Gradient Descent on Product of 4 Scalars

We focus on the simple objective $L(x, y, z, w) \triangleq \frac{1}{2}(1 - xyzw)^2$. Let the learnable parameters $x, y, z, w \in \mathbb{R}$ to be trained using gradient descent with a fixed step size $\eta \in \mathbb{R}^+$ that

$$
(x_{t+1}, y_{t+1}, z_{t+1}, w_{t+1}) = (x_t, y_t, z_t, w_t) - \eta \nabla L(x_t, y_t, z_t, w_t).
$$

Here $x_t$ denotes the value of parameter $x$ after the $t$-th update. To further simplify the problem, we consider the symmetric initialization of $z_0 = x_0, w_0 = y_0$. Note that due to symmetry of objective, the identical entries will remain identical throughout the training process, so the training dynamics reduces to two dimensional and the 1-step update of $x$ and $y$ follows

$$
x_{t+1} = x_t - x_t y_t^2 \eta (x_t^2 y_t^2 - 1), \quad y_{t+1} = y_t - x_t^2 y_t \eta (x_t^2 y_t^2 - 1).
$$

It’s easy to show that the set of global minima for this function form the hyperbola $xy = 1$. Without loss of generality we focus on the case when $x, y > 0$, and in most of the analysis we also focus on the side where $x > y$. As shown in Fig. 2, with GD running on such a minimal model, we observe convergence on EoS for a wide range
of initializations. Eventually all such trajectories converge to minima that are just slightly flatter than the “EoS minima” (the minima whose sharpness is exactly $2/\eta$; see Definition 1).

![Figure 2](image_url)

(a) Evolution of training loss, sharpness, and trajectory of GD on the 4 scalar example from the same initialization with different learning rates. (b) Initializations converging close to $\lambda = 2/\eta$ ($\eta = 0.2$)

**Figure 2: EoS phenomenon on product of 4 scalars with symmetric initialization.** In (a) we demonstrate sharpness adaptivity by running GD with learning rate $\eta = \frac{2}{5}$, $\frac{2}{10}$, $\frac{2}{15}$ from the same initialization. The sharpness of all trajectories converges to around their corresponding stability threshold $2/\eta$ while the loss decreases exponentially. In the 2D trajectory, the 2-step movement quickly converges to some smooth curves ending very close to the EoS minimum. In (b) we demonstrate sharpness concentration by running GD with constant learning rate $\eta = 0.2$ for 50000 iterations from a dense grid of initializations and plot the sharpness of their converging minima. Initializations in the red shaded area all converge to a minima with sharpness in $(2/\eta - 0.1, 2\eta)$.

### 2.2 EoS Minima and Reparameterization

Given that a wide range of initializations all converge very close to the “EoS minima” with sharpness $2/\eta$, we want to concretely characterize those points. The complete calculations are deferred to Appendix B.1. Denote $\gamma = xy$, the Hessian of the objective $L$ at $(x, x, y, y)$ admits eigenvalues

$$
\lambda_1 = \frac{1}{2} \left( (x^2 + y^2) (3\gamma^2 - 1) + \sqrt{(x^2 + y^2)^2 (1 - 3\gamma^2)^2 + 4\gamma^2 (3 - 10\gamma^2 + 7\gamma^4)} \right),
$$

$$
\lambda_2 = \frac{1}{2} \left( (x^2 + y^2) (3\gamma^2 - 1) - \sqrt{(x^2 + y^2)^2 (1 - 3\gamma^2)^2 + 4\gamma^2 (3 - 10\gamma^2 + 7\gamma^4)} \right),
$$

and $\lambda_3 = x^2 (1 - \gamma)$, $\lambda_4 = y^2 (1 - \gamma)$. When $(x, y)$ converges to any minimum, $\gamma = xy = 1$, so $\lambda_2, \lambda_3, \lambda_4$ all vanish. Therefore it is $\lambda_1$ that corresponds to the EoS phenomenon people observe. When $\eta < \frac{1}{2}$, solving $\lambda_1 = 2/\eta$ with $x^2 y^2 = 1$ gives $x = \pm \frac{\sqrt{2}}{\eta}((-4 + \eta^{-2})^{\frac{1}{4}} + \eta^{-1})^{\frac{1}{2}}$, $y = \pm \sqrt{2}((-4 + \eta^{-2})^{\frac{1}{4}} + \eta^{-1})^{-\frac{1}{2}}$ and their multiplicative inverses. These solutions correspond to the minima with sharpness exactly equal to the EoS threshold of $2/\eta$. Since they are all symmetric with each other, without loss of generality we pick the minimum of interest as follows.

**Definition 1** ($\eta$-EoS Minimum). For any step size $\eta \in (0, \frac{1}{2})$, the $\eta$-EoS minimum under the $(x, y)$-parameterization is given by

$$
(\hat{x}, \hat{y}) \triangleq \left( \frac{1}{\sqrt{2}} \left((-4 + \eta^{-2})^{\frac{1}{4}} + \eta^{-1}\right)^{\frac{1}{2}}, \sqrt{2} \left((-4 + \eta^{-2})^{\frac{1}{4}} + \eta^{-1}\right)^{-\frac{1}{2}} \right).
$$

Despite we are able to obtain a closed-form expression for the EoS minimum, its $x$-$y$ coordinate could still be tricky to analyze. Thus we consider the following reparameterization: For any $(x, y) \in \{(x, y) \in \mathbb{R}^+ \times \mathbb{R}^+: x > y\}$, define $c \triangleq (x^2 - y^2)^{\frac{1}{2}}$ and $d \triangleq xy$. This gives a bijective continuous mapping between $\{(x, y) \in \mathbb{R}^+ \times \mathbb{R}^+: x > y\}$ and $\{(c, d) \in \mathbb{R}^+ \times \mathbb{R}^+\}$. This is a natural reparameterization since intuitively the basis in the new coordinate system are the two orthogonal family of hyperbolas $xy = C$ and $x^2 - y^2 = C$. The former captures the movement orthogonal to the manifold of minima $xy = 1$ while the latter captures the movement along the manifold of minima. Note that a similar separation of dynamics was also used in Arora et al. (2022).
With $c, d$ as defined, the $\eta$-EoS minimum simplifies to $(\hat{c}, \hat{d}) \triangleq (\eta^{-2} - 4)^{\frac{1}{2}}, 1)$. To expand the dynamics near the $\eta$-EoS minimum, we let $a \triangleq c - (\eta^{-2} - 4)^{\frac{1}{2}}$ and $b \triangleq d - 1$ to be the offset from $(\hat{c}, \hat{d})$. Our analysis will primarily be using the $(a, b)$-parameterization.

**Definition 2 ($\eta$-EoS Reparameterization).** For any step size $\eta > 0$, for any $(x, y) \in \mathbb{R}^+ \times \mathbb{R}^+$ such that $x > y$, the $(a, b)$ reparameterization of $(x, y)$ are respectively given by

$$
(a, b) \triangleq \left((x^2 - y^2)^{\frac{1}{2}} - (\eta^{-2} - 4)^{\frac{1}{2}}, xy - 1\right).
$$

Let $\kappa \triangleq \sqrt{\eta}$, following Eq. (2), the 1-step update under the reparameterization becomes

$$
a_{t+1} = (\kappa^{-4} - 4)^{\frac{1}{2}} + \left(a_t + (\kappa^{-4} - 4)^{\frac{1}{2}}\right) \left(1 - ((1 + b_t)^3 - (1 + b_t))^{\frac{1}{2}} \kappa^4\right)^{\frac{1}{2}},
$$

$$
b_{t+1} = b + ((1 + b_t)^3 - 2(1 + b_t)^2 + (1 + b_t)^7)\kappa^4
+ ((1 + b_t) - (1 + b_t)^3) \left(4(1 + b_t)^2\kappa^4 + (a_t\kappa + (1 - 4\kappa^4)^{\frac{1}{2}})^4\right)^{\frac{1}{2}}.
$$

Now we can proceed to analyze the dynamics of this simple example.

## 3 Dynamics of Gradient Descent on Product of 4 Scalars

In this section, we will rigorously analyze the training dynamics characterized by Eq. (6). First we will introduce the approximation of one and two-step update and build up intuition on the dynamics. Then we will present our main theoretical results that the 4 scalar example exhibits both characterizations of EoS training.

### 3.1 Approximating 1-Step and 2-Step Updates

Here we introduce the informal approximation on Eq. (6) and the corresponding two-step updates. For cleanness of presentation we will use $\approx$ to hide all dominated terms. The rigorous statements of the approximations and corresponding proofs are deferred to Appendix B.3. When we are only describing the one/two-step dynamics, we use $a, a', a''$ to denote $a_t, a_{t+1}, a_{t+2}$ and $b, b', b''$ to denote $b_t, b_{t+1}, b_{t+2}$. Denoting $\kappa \triangleq \sqrt{\eta}$, when $\kappa, |a|, |b|$ are all not too large (see precise ranges in condition B.1), we have

$$
a' \approx a - 2b^2\kappa^3, \quad b' \approx -b - 4abc - 3b^2 - b^3;
$$

$$
a'' \approx a - 4b^2\kappa^3, \quad b'' \approx b + 8ab\kappa - 16b^3.
$$

In the approximation, $a$ is monotonically decreasing at a steady rate of $2b^3\kappa^3$ per step. The one step update of $b$ is flipping signs and contains second and third order terms of $b$. For the two-step approximation however, the oscillation behavior and the even-order terms of $b$ all cancels. This is consistent with the analysis in (Arora et al., 2022) that the two step dynamics travels along a sharpness reducing flow.

Before proceeding to analyze the discrete GD movement, we first get intuition by approximating the two-step dynamics with a simple ODE

$$
\frac{db}{da} = \frac{b'' - b}{a'' - a} = \frac{16b^3 - 8abc}{4b^2\kappa^3}.
$$

This would be the limit when $\kappa$ is going to 0 and the movement of two-step dynamics become very small. The general solution for Eq. (8) is given by

$$
b^2 = \frac{1}{2}a\kappa + \frac{1}{16}\kappa^4 + C \exp(8a\kappa^{-3})
$$

for some constant $C \in \mathbb{R}$. As $a$ decreases following Eq. (7), the trajectory converges toward the parabola $b^2 = \frac{1}{2}a\kappa + \frac{1}{16}\kappa^4$. Note that the convergence to the parabola is exponential with respect to $a$, so if $a$ is initialized positive and not too small, it will converge to a minima that is very close to $a = -\frac{1}{2}\kappa^3$ as shown in Fig. 3. This is a minimum that is just slightly flatter than the $\kappa^2$-EoS minimum.

![Figure 3: Solutions of Eq. (8) ($\kappa = 1$)](image-url)
3.2 Convergence on EoS for Product of 4 Scalars

Now we state our convergence result on the 4 scalar objective under $(a, b)$-parameterization.

**Theorem 3.1** (Sharpness Concentration). For a large enough absolute constant $K$, suppose $\kappa < \frac{1}{2000\eta^2} K^{-1}$, and the initialization $(a_0, b_0)$ satisfies $a_0 \in (12\kappa^{\frac{3}{2}}, \frac{1}{2}K^{-2}\kappa^{-1})$ and $b_0 \in (-K^{-1}, K^{-1}) \setminus \{0\}$. Consider the GD trajectory characterized in Eq. (6) with fixed step size $\kappa^2$ from $(a_0, b_0)$, for any $\epsilon > 0$ there exists $T = \mathcal{O}(K^{-2} \kappa^{-\frac{3}{2}} + \log(\epsilon^{-1}) + \log(|b_0|^{-1})\kappa^{-\frac{3}{2}})$ such that for all $t > T$, $|b_t| < \epsilon$ and $a_t \in [-\frac{5}{4}\kappa^3, -\frac{1}{10}\kappa^3)$.

Under the context of $x, y$ coordinate and sharpness, Theorem 3.1 gives the following corollary:

**Corollary 3.1** (Sharpness Concentration under $(x, y)$-Parameterization). For a large enough absolute constant $K$, suppose $\eta < \frac{1}{2000\kappa^2} K^{-2}$, and the initialization $(x_0, y_0)$ satisfies $x_0 \in (\tilde{x} + 13\eta^2, \tilde{x} + \frac{1}{2}K^{-2}\eta^{-\frac{3}{2}})$ and $|x_0 - y_0| \in (0, K^{-1})$ where $(\tilde{x}, \tilde{y})$ is the $\eta$-EoS minima defined in Definition 1. The GD trajectory characterized in Eq. (2) with fixed step size $\eta$ will converge to a global minimum with sharpness $\lambda \in \left\{ \frac{2}{\eta} - \frac{20}{\eta^2} \eta, \frac{2}{\eta} \right\}$.

Note that when the step size $\eta$ (and hence $\kappa$) is relatively small, the final sharpness is very close to $2/\eta$. The range of initialization that satisfies the requirement is quite large, in the original $(x, y)$-parameterization it contains a box of width $\Theta(K^{-2}\eta^{-\frac{3}{2}})$ and height $\Theta(K^{-1}\eta^{-\frac{3}{2}})$, many of the initial points can be far from the EoS-minimum.

The complete proofs are deferred to Appendix B.6. Here we discuss the proof sketch of Theorem 3.1. Our convergence analysis focuses on the 2-step update. It contains two phases:

**Phase 1. (Convergence to near parabola)**
We consider initializations in region I, II, and III.

- In I, $b'' - b$ is dominated by $-b^3$ and $(a, b)$ follows an exponential trajectory. We show that $|b|$ decreases exponentially with respect to $a$ and enters region II (Lemma 8).
- In III, $b'' - b$ is dominated by $abc$ and $(a, b)$ follows an elliptic trajectory centered at $(0, 0)$. We show that $|b|$ increases at superlinearly with respect to $a$ and enters II (Lemma 9).
- We also show that once $(a, b)$ enters II, it will stay in II until it exits from the left and enters IV (Lemma 11). Thus after Stage 1, all initializations will be in IV.

**Phase 2. (Convergence along parabola)**
- After $(a, b)$ enters IV, we show that it will further converge to the parabola that $|b^2 - \frac{1}{3}a\kappa - \frac{1}{4}\kappa^4| < \frac{20}{\eta^2}\kappa^4$ will be satisfied before $a$ decreases to $\kappa^2$ and enters V (Lemma 13).
- Then we show that the inequality will be preserved in V while it moves left until it enters VI (Lemma 14).
- In VI, the dynamics is again similar to III, but with $a$ being negative. We conclude our proof by showing $|b|$ will converge to 0 superlinearly with respect to $a$ (Lemma 15).

Following Theorem 3.1, we can also formally characterize the sharpness adaptive phenomenon for a local region using the following corollary. The proof is deferred to Appendix B.6.2.

**Corollary 3.2** (Sharpness Adaptivity). For a large enough constant $K$, fix any $\alpha < \frac{1}{2000\sqrt{2}} K^{-1}$. For all initialization $(x_0, y_0)$ in the region characterized by
\[
    x_0 \in (\alpha^{-1} + \frac{1}{11}K^{-2}\alpha^{-1}, \alpha^{-1} + \frac{1}{2}K^{-2}\alpha^{-1})
\]
and $|x_0 - y_0| \in (0, K^{-1})$, the GD trajectory from $(x_0, y_0)$ characterized by Eq. (2) with any step size $\eta$ in $(\alpha^2 - \frac{1}{11}K^{-2}\alpha^2, \alpha^2)$ will converge to a minima with sharpness $\lambda \in \left\{ \frac{2}{\eta} - \frac{20}{\eta^2} \eta, \frac{2}{\eta} \right\}$.
Inspired by the scalar factorization problem, we extend it to a rank-1 factorization of an isotropic matrix. In particular, we consider the following optimization problem:

\[
\min_{x,y \in \mathbb{R}^d} \frac{1}{2} || I_d \times d - x y^\top x y ||_F^2
\]  

(11)

Similar to the under-parameterized case in Wang et al. (2022), this problem also guarantees the alignment between \( x \) and \( y \) if \( (x, y) \) is a global minimum, i.e., \( x = c y \) for some \( c \in \mathbb{R} \). To prove the convergence for Eq. (11) at the edge of stability, we first prove the alignment can be soon achieved. After the alignment, we prove the equivalence between this problem and the case of the product of 4 scalars, and prove the convergence of this problem.

We directly give the final theorem and the proof is deferred to Appendix C.

**Theorem 3.2.** For a large enough absolute constant \( K \), with all the initialization \((x_0, y_0)\) satisfying \( x_0 \sim \delta_x \text{Unif}(S^{d-1}), \ y_0 \sim \delta_y \text{Unif}(S^{d-1})^2 \), \( \delta_x \delta_y = \frac{1}{2} \), \( \delta_x \in (\bar{x} + \frac{1}{\log(K^{-2} - \frac{\log(\eta)}{2})}, \bar{x} + \frac{1}{\log(K^{-2} - \frac{\log(\eta)}{2})}) \), if step size \( \eta < \min\{\frac{K^{-4}}{16}, \frac{K^{-2}}{24\log(d) - \log(\eta)}\} \), and a multiplicative perturbation \( y'_t = y_t \cdot (1 + 2K^{-1}) \) is performed at time \( t = t_p \) for some \( t_p > \mathcal{O}(-\log(\eta) + \log(d) - \log(\delta_y) + K^3) \), then for any \( \epsilon > 0 \), with probability \( p > 1 - 2\delta_t - 2\exp\{-\Omega(d)\} \) there exists \( T = \mathcal{O}(K^{-2}\kappa^{-12} - \log(\epsilon) - \log(\delta_0)) \) such that for all \( t > T \), \( \mathcal{L}(x, y < \epsilon \) and \( ||x||^2 + ||y||^2 \in (\frac{1}{1 - \frac{10}{K^2} \eta}, \frac{1}{K^2} \eta) \).

Note that we require an additional perturbation because we need to guarantee that the trajectory does not converge to an unstable point (where sharpness \( \lambda > 2/\eta \)). This was proved without perturbation for the scalar case but is more challenging in higher dimensions. The objective will still converge to a minimum very close to an \( \eta \)-EoS minimum.

### 4 Differences in Degree-2 and High Degree Models

In this section, we will look at some similar models of lower degree, and explain why for degree-2 models the sharpness of final converging point is often farther from \( 2/\eta \) compared to higher degree models. We will use similar methods as in Section 2 and Section 3 to gain intuition for the dynamics. We also empirically investigate the training dynamics for more general scalar networks.

#### 4.1 GD on 2-Component Scalar Factorization

Previous works including (Chen & Bruna, 2022) and (Wang et al., 2022) have studied the dynamics of beyond EoS training on the problem of factorizing a single scalar or an isotropic matrix into two components. The objectives studied includes \( \min_{x, y \in \mathbb{R}^d} ||\mu - xy||^2 \), \( \min_{x, y \in \mathbb{R}^d} ||\mu I_d - xy^\top||_F^2 \), and the corresponding scalar case \( \min_{x, y \in \mathbb{R}} ||\mu - xy||^2 \). They were able to show that for initializations with sharpness greater than \( 2/\eta \), GD with constant learning rate \( \eta \) provably converges to a global minimum with sharpness less or equal to \( 2/\eta \). Empirically, the sharpness reduction process on these 2-component objectives will usually “overshoot” the EoS threshold and converge to a minima that is significantly flatter than the EoS minimum, and one does not observe the oscillation of sharpness around the EoS threshold (see Appendix A.3).

In this section we consider the scalar objective \( \min_{x, y \in \mathbb{R}} (1 - xy)^2 \) since it is able to captures the major dynamical properties of those more complex objectives as discussed in Wang et al. (2022). As shown in Fig. 5, initializations with sharpness exceeding the EoS threshold will converge to a minima that is distinguishably flatter than the EoS minimum, and globally there is not a region of initialization that gives EoS convergence. Unlike the parabola for the 4 scalar case, the two step update travels in a roughly circular trajectory centered at the \( \kappa^2 \)-EoS minimum as shown in Fig. 5a (right). Therefore locally we observe that sharper initializations tend to converge to flatter minima.

The difference between the 2 scalar and 4 scalar case can be easily explained by a local expansion. Using the same \((c, d)\)-reparameterization and setting \((a, b)\) to be the offset of \((c, d)\) from the EoS minimum, the two step update of
\((a, b)\) under learning rate \(\kappa^2\) can be approximated by

\[
a'' \approx a - \sqrt{2}b^2\kappa^3, \quad b'' \approx b + 4\sqrt{2}ab\kappa.
\]

(12)

This is very similar to Eq. (7) except that we no longer have the \(-b^3\) term for the 2-step update on \(b\) which was attracting \(b\) close to 0. In this case, the ODE approximation \(db/da = 4a/bc^2\) gives the general solution \(b^2 = 4(C - a^2)/c^2\) for \(C \in \mathbb{R}^+\), which corresponds to the family of ellipses centered at \((0, 0)\) and matches the two step trajectory in Fig. 5a.

\[\text{Figure 5: Beyond EoS training on product of two scalars.}\] We run the same experiment as in Fig. 2 except for using objective \(\min_{x,y \in \mathbb{R}} (1 - xy)^2\). Note that in this case the two-step trajectories form circular curves and converge to points that are farther from EoS minima.

4.2 GD on 3-Layer Scalar Networks

Now we look into an interesting example with different behaviors around different EoS minima. We consider a 3-layer scalar network with objective \(\min_{x,y,z \in \mathbb{R}} \frac{1}{2}(1 - xyz)^2\) and initialization with \(z = y\). The equality of the last two entries will be preserved through training so the dynamics is two dimensional in terms of \(x\) and \(y\). In the positive quadrant, the global minima is \(\sqrt{xy} = 1\) and there are two EoS minima. In Fig. 6, we plot the converging sharpness from different initializations in comparison with Fig. 2b and Fig. 5b.

Around the EoS minimum that the single entry \(x\) is small and the duplicated entries \(y\) are large (upper left of Fig. 6), the behavior is similar to the 2 scalar case (Fig. 5b) with no sharpness concentration. Around the EoS minima with large single entry and small duplicating entries (lower right of Fig. 6), we have a region of initialization (the red shaded area) with sharpness concentration similar to the 4 scalar case (Fig. 2b).

A heuristic explanation to this difference lies in the difference in the degree of the small entries. Around the EoS minima that the single entry is small, the local two-step approximation is similar to Eq. (12) and gives us elliptical two-step trajectories. Around the minima with small duplicating entries, the two-step approximation would contain the cubic term as in Eq. (7), which gives us both sharpness concentration and adaptivity. We note that empirically similar phenomenon is also true for more general scalar networks without symmetric initializations. See Appendix A.4.
5 Global Trajectory and Chaos

There exists very limited global convergence analysis for constant step size gradient descent training beyond EoS on complicated non-convex objectives. Even for the product of 4 scalars, the boundary separating converging and diverging initializations (Fig. 7a) exhibits complicated fractal structures.

Moreover, we observe that for initializations close to such boundary, their GD training trajectories usually begin with a phase of chaotic oscillation which eventually “de-bifurcates” and converges to the parabolic two-step trajectory as discussed in Section 3. Similar oscillation phenomenon has also been empirically observed by Ruiz-Garcia et al. (2021) in neural networks when they increase the learning rate and destabilize the network from a local trajectory.

Figure 7: Bifurcation behavior of GD on the 4 scalar example. In (a) we show the zoomed in version of the lower right part of Fig. 2b, the fractal boundary can be clearly observed. In (b), we run GD with \( \eta = 0.01 \) starting from the asymmetric initialization \((x_0, y_0) = (12.5, 0.05)\) close to the boundary of divergence until it converge close to the EoS minimum at around \((10, 0.1)\). In (c), we plot the trajectory with bifurcation under \((a, b)\)-reparameterization and compare it with the bifurcation diagram of the approximated dynamical system characterized by Eq. (13).

So what is causing the bifurcation? Previously, Ruiz-Garcia et al. (2021) attributed the phenomenon to the cascading effect of oscillation along multiple eigendirections of the network. Yet this explanation is quite unsatisfying for our simple model as there is only one oscillating direction.

Looking closely to the trajectory (Fig. 7b), one will find it very similar to the bifurcation diagram of self-recurrent polynomial maps (such as the famous logistic map) parameterized by \( r \). In the 4-scalar example, the existence of such self-recurrent map is explicit since following Eq. (7), the approximate 2-step update of \( b \) can be rewritten as

\[
b'' = b(1 + 8arb - 16b^2). \tag{13}
\]

If we consider \( a \) to be relatively stationary, the trajectory of \( b \) will be locally characterized by the self-recurrent 1D nonlinear dynamical system Eq. (13) parameterized by \( a \). In Fig. 7c, we compute the bifurcation diagram for Eq. (13) numerically and see that they are qualitatively similar. Following this analogy, one may instantly relate the first bifurcating point with the EoS minima that the trajectory eventually converges to, and the non-bifurcating regime for the polynomial maps with the “sub-EoS regime” on the left (in Fig. 7b) of the EoS minima.

6 Discussion and Conclusion

In this paper we proposed a simple degree-4 model that captures the sharpness adaptivity and sharpness concentration phenomena that happen in gradient descent training of deep neural networks. The simplicity of the model allowed us to perform rigorous analysis on the training dynamics for a large local region. The analysis gives new insights on why the training dynamics of the degree-4 model is inherently different from the training dynamics...
of degree-2 models. We hope many of these observations can be generalized to highlight the difference between training dynamics of deeper networks and the shallower models.

There are still many open problems. Even for this simple objective the global dynamics is already very complicated. Is there a way to understand and leverage the fractal/bifurcation behavior in Section 5? Another interesting open question is how to characterize the training dynamics for other gradient based algorithms (such as GD with momentum and versions of adaptive gradient).

A Additional Experiments

In this section, we provide more empirical evidences supporting the main text.

In Appendix A.1 we will first introduce our experiment setup including the structure and initialization for the neural network models as well as the generative model for the synthetic datasets.

Then in Appendix A.2 we will present some additional figures demonstrating the training dynamics near the EoS minima for the 2, 3, 4-scalar examples discussed in Section 3 and Section 4.

Finally in Appendix A.4 we will present more empirical results on the training dynamics of general scalar networks.

A.1 Experiment Settings

A.1.1 Calculation of Numerical Sharpness

For the scalar network examples the closed-form Hessian is simple. We compute the exact parameter Hessian and use numerical packages to compute its top eigenvalue.

For neural networks, we use the PyHessian package by (Yao et al., 2020), which compute the top eigenvector eigenvalue pair by inferencing the Hessian vector product and do power iteration. For all numerical sharpness computed for neural networks, we set $\text{tol}=1e-6$ and $\text{max.iter}=10000$.

A.1.2 Neural Networks Models

For all experiments involving neural networks, we use fully connected networks with the same dimension for input, output, and all hidden layers. The bias of all layers are fixed to 0. Formally, a $L$-layer width $d$ network can be modeled by $f : \mathbb{R}^d \rightarrow \mathbb{R}^d$ such that for input vector $x \in \mathbb{R}^d$,

$$f(x) = W_L \sigma(W_{L-1} \ldots \sigma(W_2 \sigma(W_1 x))) \ldots$$ (14)

where $\sigma : \mathbb{R}^d \rightarrow \mathbb{R}^d$ is some entry-wise activation function and $W_l \in \mathbb{R}^{d \times d}$ for all $l \in [L]$. For this paper we only considered $\sigma$ being the ReLU activation $\sigma(x) = x 1_{x \geq 0}$ or the identity $\sigma(x) = x$.

Initialization of Neural Networks

We use Xavier initialization (Glorot & Bengio, 2010) with gain of 1 to initialize the all weight matrices. For shallow two-layer networks that will not enter the EoS regime if using completely random initialization, we will asymmetrically re-scale the layers after random initialization by multiplying a constant to all entries of the same layer. When we present results for the re-scaled experiments, we will state the re-scale factor.

Synthetic Dataset and Loss Function

For the experiments involving neural networks, we use synthetic datasets very similar to the linear network experiment in section L.3 of Cohen et al. (2021). For a neural network as described above with dimension $d$, we consider the problem of mapping $n$ inputs $x_1, \ldots, x_n \in \mathbb{R}^d$ to $n$ outputs $y_1, \ldots, y_n \in \mathbb{R}^d$. Let $X \in \mathbb{R}^{d \times d}$ and $Y \in \mathbb{R}^{d \times d}$ denote the vertically stack inputs and outputs respectively. We generate $X$ as a whitened matrix such that $XX^T = dI_d$ and generate $Y$ by $Y = X A$ where $A = \text{diag}(1, \frac{d-1}{d}, \ldots, \frac{2}{d}, \frac{1}{d})$.

For all experiments with neural networks, we consider the simple squared loss

$$\frac{1}{d} \sum_{i=1}^{d} \|f(x_i) - y_i\|_2^2,$$ (15)

which matches our analysis on scalar networks.
A.2 Local Training Dynamics for Scalar Networks

In this section we show some additional figures demonstrating the local training dynamics for the two cases we analyzed in Section 3 and Section 4.

A.2.1 4-Layer Scalar Network

Figure 8: Sharpness concentration for the 4-scalar example. We run GD with $\eta = 0.2$ from 3 initializations that are above, below, and very close to the line of global minima. The sharpness of all trajectories converges to around $2/\eta$ while the loss decreases exponentially. In the 2D trajectory, the 2-step movement quickly converges to the parabolic curves ending very close to the EoS minimum.
Figure 9: **Local two-step movement for the 4-scalar example.** We record the two-step movement with $\eta = 0.2$ from a grid of initializations near the EoS minima. At each point, the arrow points toward the direction of two-step movement from that point and the color of arrow indicates the converging sharpness of trajectories passing that point. We can see the parabolic trajectory and how initialization to the right of the EoS minima all tend to converge to it.

A.2.2 2-Layer Scalar Network

Figure 10: **Beyond EoS training on product of two scalars.** We run the identical experiment as in Fig. 8 except for the objective $\min_{x,y \in \mathbb{R}} (1 - xy)^2$. Note that in this case we do not observe both sharpness concentration and sharpness adaptivity. The two-step trajectory follows an elliptical trajectory centered at the EoS minima. In this context, a sharper initialization (e.g. the purple curve) will eventually converge to a flatter minima (as shown in the left figure).
Figure 11: **Local two-step movement for the 2-scalar example.** This is the same figure as Fig. 9 except for the 2-scalar example. We use the same step size $\eta = 0.2$. There is no longer the concentration behavior as we see for the 4-scalar case. Locally, only the initialization very close to the EoS minimum will converge to a sharpness near the stability threshold (which is 10 with $\eta = 0.2$).

### A.2.3 3-Layer Scalar Network

Figure 12: **Local two-step movement for the 3-scalar example.** In this figure, we show the local dynamics near the two EoS minima in the positive quadrant of the 3-scalar example. The left figure corresponds to the EoS minima at the lower right of Fig. 6. At this EoS minima, the duplicated entry $y$ is small, and the local behavior is very similar to the case of 4-scalar example (Fig. 9) for which we have provable sharpness concentration. The right figure corresponds to the EoS minima at the top left of Fig. 6. The local behavior is very similar to the case of 2-scalar example (Fig. 11), for which we do not have EoS behaviors.
A.3 Additional Experiments for 2-Component Scalar Factorization

In this section we present the experiment results for 2-component scalar factorization deferred from Section 4.1. The dynamics as shown in Fig. 13 is very similar to the 2-scalar example in Fig. 10.

![Figure 13: GD on 2-component scalar factorization problems. We run gradient descent with $\eta = 0.05$ for two different objectives. Both models are asymmetrically initialized with factor $(5, 0.1)$ so that they have an initial sharpness larger than $2/\eta$. For both cases, the converging sharpness is distinguishably smaller than the stability threshold.](image-url)
A.4 Additional Experiments for General Scalar Networks

In this section, we will present some empirical observations on training dynamics of more general scalar networks related to the sharpness concentration and adaptation phenomena. A $n$-layer scalar network is defined to be the model parameterized by $n$ entries $x_1, \ldots, x_n \in \mathbb{R}$ with objective

$$
L(x_1, \ldots, x_n) \triangleq \frac{1}{2} \left(1 - \prod_{i=1}^{n} x_i\right).
$$

(16)

A.4.1 Initialization without Duplicated Entries

We first consider a variant of the 3-scalar example as discussed in Section 4.2. In particular, we initialize the two small entries differently and record their values throughout the training trajectory.

Figure 14: This figure records the training loss (left) and sharpness (middle) of a 3-layer scalar network with initialization $(6, 0.1, 0.4)$ optimized by gradient descent with fixed step size $\eta = 0.2$. In (right) we plot the distance of the last entry $x_3$ to other entries.

As we can see in Fig. 14, at the very beginning of the training, the second entry $x_2$ converges to $x_3$ geometrically, then the dynamics is reduced to the case of duplicated entries, which we know that the sharpness concentration behavior would happen for sufficiently asymmetric initialization. In Fig. 15 we consider a 7-layer scalar network with 3 different large entries and 4 different small entries. We observe similar behavior as $x_4$, $x_5$, $x_6$ all converges to $x_7$ geometrically, and we observe concentration of sharpness with 4 duplicated small entries.

Figure 15: This figure records the training loss (left) and sharpness (middle) of a 7-layer scalar network with initialization $(2, 2.5, 3, 0.1, 0.2, 0.3, 0.4)$ optimized by gradient descent with fixed step size $\eta = 0.2$. In (right) we plot the distance of the last entry $x_7$ to other entries.

To probe into the detailed training dynamics of general scalar networks, we plot the pairwise dynamics of the entries as shown in Fig. 16.
Figure 16: **Pairwise Training Dynamics.** This set of figures record the pairwise training dynamics for entries $x_2, x_3, x_4, x_5$ in the same experiment as Fig. 15. $x_2$ and $x_3$ are initialized large while $x_4$ and $x_5$ are initialized small. We see that within the small entries and the large entries, the pairwise dynamics are all approximately linear while the cross comparisons across the small entries and large entries gives the parabolic two-step trajectory (and also some bifurcation behavior).

Figure 17: **Single Entry Movement.** We plot the value of $x_3$ (initialized to 3) and $x_3$ (initialized to 0.1) along the training process. The larger entry decreases in an approximately monotone manner and the small entry increase while oscillating.

### A.4.2 On “Large” and “Small” Initializations

In the experiments shown above, we have seen that there are mainly two classes of behaviors for the entries: the entries that were initialized to be large moves slowly with little oscillation while the entries that were initialized to be small has significant oscillation along the trajectory. Intuitively, it is the decreasing large entry that decreases the sharpness and stabilizes the oscillating small entries and result in the final convergence close to the EoS minimum. A natural question to ask is whether there exists a clear boundary separating the “small” and “large” entries.

We consider a 4-layer scalar network with initialization $(6, 0.7, 0.3, 0.2)$ optimized with GD with step size $\eta = 0.2$. In Fig. 18 and Fig. 19 we visualize the training loss, sharpness, and the pairwise dynamics. The mixed behaviors
suggests a clear boundary between the “large” and “small” entries does not exists, and the complexity of this problem is beyond this simple heuristics.

Figure 18: This figure records the training loss (left) and sharpness (middle) of a 4-layer scalar network with initialization $(6, 0.7, 0.3, 0.2)$ optimized by gradient descent with fixed step size $\eta = 0.2$. In (right) we plot the distance of the last entry $x_4$ to other entries. In this example, the small entries did not converge to be exactly the same value, yet the loss still decreased geometrically and the sharpness concentration phenomenon still occurred.

Figure 19: **Pairwise Training Dynamics.** This set of figures record the pairwise training dynamics for entries $x_1, x_2, x_3, x_4$ in the same experiment as Fig. 18. $x_1$ was initialized large (at 6), $x_3, x_4$ were initialized small (at 0.2, 0.3), and $x_2$ was initialized moderately small (at 0.7). We see that the two-step pairwise dynamics between $x_2$ and $x_3$ roughly follows a parabolic trajectory, yet the pairwise dynamics between $x_1$ and $x_2$ also exhibits similar features while still following a roughly linear relation.
B Theoretical Analysis on the 4-Scalar Example

In this section we present the complete rigorous analysis on the training dynamics of the 4-scalar example discussed in Section 3. The section will be organized in the following way:

In Appendix B.1 we will first define the problem and two reparameterizations we used for analysis, this serves as a more comprehensive version of Section 2 in the main text.

In Appendix B.2 we will first restate our main theorem for the 4-scalar example (Theorem 3.1) along with two corollaries (Corollary 3.1, and Corollary 3.2). These theoretical results characterized the sharpness concentration and sharpness adaptivity phenomenon of the 4-scalar example. Then we will provide a more comprehensive proof sketch for Theorem 3.1 that is similar to the discussion in Section 3.2 of the main text.

Then we will provide the lemmas for dynamics approximation (Appendix B.3), phase I convergence (Appendix B.4), and phase II convergence (Appendix B.5).

Finally, in Appendix B.6 we will use the lemmas to complete the proof for the main theorem along with its corollaries.

B.1 Preliminaries

We consider a simple objective function \( L(x, y, z, w) = \frac{1}{4}(xyzw - 1)^2 \). Denote \( \gamma := xyzw \), then

\[
\nabla L(x, y, z, w) = (\gamma^2 - \gamma)[x, y, z, w]^{-1},
\]

\[
\nabla^2 L(x, y, z, w) = (\gamma^2 - \gamma) \begin{bmatrix}
\frac{\gamma^2}{x^2} & \frac{(2\gamma^2 - \gamma)}{xy} & \frac{(2\gamma^2 - \gamma)}{xz} & \frac{(2\gamma^2 - \gamma)}{xw} \\
\frac{(2\gamma^2 - \gamma)}{xy} & \frac{\gamma^2}{y^2} & \frac{(2\gamma^2 - \gamma)}{yz} & \frac{(2\gamma^2 - \gamma)}{yw} \\
\frac{(2\gamma^2 - \gamma)}{xz} & \frac{(2\gamma^2 - \gamma)}{yz} & \frac{\gamma^2}{z^2} & \frac{(2\gamma^2 - \gamma)}{zw} \\
\frac{(2\gamma^2 - \gamma)}{xw} & \frac{(2\gamma^2 - \gamma)}{yw} & \frac{(2\gamma^2 - \gamma)}{zw} & \frac{\gamma^2}{w^2}
\end{bmatrix}.
\]

Let the parameter \([x, y, z, w] \) to be optimized by gradient descent with step size \( \eta \), that

\[
[x(t+1), y(t+1), z(t+1), w(t+1)] = [x(t), y(t), z(t), w(t)] - \eta \nabla L(x(t), y(t), z(t), w(t)).
\]

To further simplify the problem, we consider the symmetric initialization of \( z_0 = x_0, w_0 = y_0 \). Note that due to symmetry of objective, the identical entries will remain identical throughout the training process, so the training dynamics reduces to two dimensional, and the global minima is simply \( S = \{ (x, y) \in \mathbb{R}^2 : x^2y^2 = 1 \} \). Computing the closed-form of the gradient, we know the 1-step update of \( x \) and \( y \) follows

\[
x_{t+1} = x_t - x_t y_t^2 \eta(x_t y_t^2 - 1), \quad y_{t+1} = y_t - x_t^2 y_t \eta(x_t^2 y_t^2 - 1).
\]

Denote \( \gamma = xy \), the parameter Hessian of the objective \( L \) at \([x, y, x, y] \) admits eigenvalues \( \lambda_1 = x^2(1 - \gamma) \), \( \lambda_2 = y^2(1 - \gamma) \) and

\[
\lambda_3 = \frac{1}{2} \left( (x^2 + y^2) (3\gamma^2 - 1) - \sqrt{(x^2 + y^2)^2(1 - 3\gamma^2)^2 + 4\gamma^2(3 - 10\gamma^2 + 7\gamma^4)} \right),
\]

\[
\lambda_4 = \frac{1}{2} \left( (x^2 + y^2) (3\gamma^2 - 1) + \sqrt{(x^2 + y^2)^2(1 - 3\gamma^2)^2 + 4\gamma^2(3 - 10\gamma^2 + 7\gamma^4)} \right).
\]

When \((x, y)\) converges to any minimum, \( \gamma = x^2y^2 = 1 \), so \( \lambda_1, \lambda_2, \lambda_3 \) all vanishes. Therefore it is \( \lambda_4 \) that corresponds to the EoS phenomenon people observe. When \( \eta < \frac{1}{2} \), solving \( \lambda_4 = 2/\eta \) with \( x^2y^2 = 1 \) gives

\[
x = \pm \sqrt{2}/2 \left( (-4 + \eta^{-2})^{1/2} + \eta^{-1} \right)^{1/2},
\]

\[
y = \pm \sqrt{2}/2 \left( (-4 + \eta^{-2})^{1/2} + \eta^{-1} \right)^{-1/2}
\]

and their multiplicative inverses. These solutions correspond to the minima with sharpness exactly equal to the EoS threshold of \( 2/\eta \). Since they are all symmetric with each other, without loss of generality we pick the minimum of interest as

\[
(\dot{x}, \dot{y}) \triangleq \left( \frac{1}{\sqrt{2}} \left( (-4 + \eta^{-2})^{1/2} + \eta^{-1} \right)^{1/2}, \frac{\sqrt{2}}{2} \left( (-4 + \eta^{-2})^{1/2} + \eta^{-1} \right)^{-1/2} \right).
\]

To better analyze the dynamics under a more natural coordinate, we consider the reparameterization that For any \((x, y) \in \{ (x, y) \in \mathbb{R}^+ \times \mathbb{R}^+ : x > y \} \), define

\[
c \triangleq (x^2 - y^2)^{1/2}, \quad d \triangleq xy.
\]
This gives a bijective continuous mapping between \(\{(x, y) \in \mathbb{R}^+ \times \mathbb{R}^+ : x > y\}\) and \(\{(c, d) \in \mathbb{R}^+ \times \mathbb{R}^+\}\). Intuitively, we are taking the lower half of \(y = 1/x\) on the positive quadrant as \(d = 1\). With \(c, d\) as defined, the \(\eta\)-EoS minimum simplifies to \((\bar{c}, \bar{d}) \triangleq ((\eta^{-2} - 4)^{\frac{1}{4}}, 1)\). The inverse map can be computed as
\[
x = \frac{\sqrt{c^2 + \sqrt{c^4 + 4d^2}}}{\sqrt{2}}, \quad y = \frac{\sqrt{2d}}{\sqrt{c^2 + \sqrt{c^4 + 4d^2}}},
\]
To expand the dynamics near the \(\eta\)-EoS minimum, we define
\[
a \triangleq c - (\eta^{-2} - 4)^{\frac{1}{4}}, \quad b \triangleq d - 1
\]
to be the offset from \((\bar{c}, \bar{d})\). Our analysis will primarily be using the \((a, b)\)-parameterization. To summarize, the \((c, d)\) and \((a, b)\) reparameterization of \((x, y)\) are respectively given by
\[
(c, d) \triangleq \left((x^2 - y^2)^{\frac{1}{2}}, xy\right), \quad (a, b) \triangleq \left((x^2 - y^2)^{\frac{1}{2}} - (\eta^{-2} - 4)^{\frac{1}{4}}, xy - 1\right).
\]
Let \(\kappa \triangleq \sqrt{n}\), under the reparameterization Eq. (20) becomes.
\[
a_{t+1} = (\kappa^{-4} - 4)^{\frac{1}{4}} + \left(a_t + (\kappa^{-4} - 4)^{\frac{1}{4}}\right) \left(1 - ((1 + b_{t})^3 - (1 + b_{t}))^2 \kappa^4\right)^{\frac{1}{2}},
\]
\[
b_{t+1} = b + ((1 + b_{t})^3 - 2(1 + b_{t})^5 + (1 + b_{t})^7)\kappa^4 + (1 + b_{t} - (1 + b_{t})^3) \left(4(1 + b_{t})^2 \kappa^4 + (a_t \kappa + (1 - 4\kappa^4)^{\frac{1}{4}})^{\frac{1}{2}}\right)\frac{1}{2}.
\]

**B.2 Theoretical Results and Proof Sketch**

Now with the reparameterization defined, we restate our convergence result on the 4 scalar objective and discuss the proof sketch.

**Theorem 3.1 (Sharpness Concentration).** For a large enough absolute constant \(K\), suppose \(\kappa < \frac{1}{2000\sqrt{2}} K^{-1}\), and the initialization \((a_0, b_0)\) satisfies \(a_0 \in (12\kappa^{\frac{1}{2}}, \frac{1}{4} K^{-2} \kappa^{-1})\) and \(b_0 \in (-K^{-1}, K^{-1})\setminus\{0\}\). Consider the GD trajectory characterized in Eq. (6) with fixed step size \(\kappa^2\) from \((a_0, b_0)\), for any \(\epsilon > 0\) there exists \(T = \mathcal{O}(K^{-2} \kappa^{-\frac{12}{5}} + \log(\epsilon^{-1}) + \log(|b_0|^{-1}) \kappa^{-\frac{1}{5}})\) such that for all \(t > T\), \(|a_t| < \epsilon\) and \(a_t \in (-\frac{5}{2} \kappa^3, -\frac{1}{10} \kappa^3)\).

**B.2.1 Proof Sketch of Theorem 3.1**

Our analysis begins with approximating the local movement using primarily Taylor expansion around the \(\kappa^2\)-EoS Minimum (Appendix B.3). We show that for initialization within a local region of width \(2K^{-2}\kappa^{-1}\) and height \(2K^{-1}\) centered at the \(\kappa^2\)-EoS minimum (condition B.1), the local two-step update of \(a\) and \(b\) can be characterized by
\[
a'' = a - 4b^2 \kappa^3 + R_a, \quad b'' = b - 16b^3 + 8ab \kappa + R_b.
\]
Where \(R_a, R_b\) are remainders that we can effectively bound (Corollary B.1). We note that in the region we are considering, \(a\) is always monotonically decreasing at \(b^2 \kappa^3\) per 2 steps (Lemma 5).

With the approximation ready, we will conduct our convergence analysis with 2 phases.
In Phase 1 (Appendix B.4), we consider all possible initializations \((a_0, b_0)\) such that \(a_0 \in (12\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1})\) and \(b_0 \in (-K^{-1}, K^{-1})\setminus\{0\}\). We partition the region of initializations into three parts separated by \(b^2 = 2a\kappa\) and \(b^2 = \frac{1}{2}a\kappa\) (shown as region I, II, III in Fig. 20).

- For initializations in region I where \(b^2 > 2a\kappa\) (condition B.3), we show that the cubic term \(b^3\) in the expression of \(b''\) in Eq. (29) dominates the \(abc\) term as well as the remainder, so that the two step update on \(|b|\) is monotonically decreasing with at least an additive update of \(-|b|^3\). Combining with slow movement of \(a\), we show that initializations in region I will quickly enter region II (Lemma 8).

- For initializations in region III where \(b^2 \in (0, \frac{1}{2}a\kappa)\) (condition B.4), we show that the \(abc\) term will dominate the \(b^3\) term and other remainders. Thus the two-step update of \(|b|\) will monotonically increase with a multiplicative rate of at least \((1 + a\kappa)\). Combining with slow movement of \(a\), we show that initializations in region III will also quickly enter region II (Lemma 9).

- For the last step in Phase 1, we show that the 2-step trajectories entering region II will stay in the region in the sense that \(b^2 \in (\frac{1}{4}a\kappa, 2a\kappa)\). (Lemma 11) We also show that \(a\) will keep decreasing and enter \((\frac{3}{2}\kappa^2, 2\kappa^2)\). In the diagram (Fig. 20) this corresponds to the phase of entering region IV from II.

At the end of Phase 1, we would have shown that all trajectories starting from the required initialization will converge to near the parabola \(b^2 = \frac{1}{2}a\kappa\) and enter region IV from the right.

In Phase 2 (Appendix B.5), we begin with initialization \((a_0, b_0)\) such that \(a_0 \in (\frac{3}{2}\kappa^2, 2\kappa^2)\) and \(b_0^2 \in (\frac{1}{2}a_0\kappa, 2a_0\kappa)\). In phase 1 we have shown a rough convergence result close to the parabola \(b^2 = \frac{1}{2}a\kappa\) with the extreme point of \((0, 0)\). In phase 2 we will change the parabola of interest to be \(b^2 = \frac{1}{4}a\kappa + \frac{1}{16}\kappa^4\) which is characterized by the ODE approximation as discussed in Section 3.1. In particular we will focus on the residual \(\xi \triangleq b^2 - \frac{1}{2}a\kappa - \frac{1}{16}\kappa^4\). The phase 2 convergence has the following three stages. Throughout the analysis we fix a small constant \(\delta = 0.04\)

- **Stage 1.** After the trajectory enters \(a \in (\frac{3}{2}\kappa^2, 2\kappa^2)\) and \(b^2 \in (\frac{1}{2}a\kappa, 2a\kappa)\), we will show that the two-step update of \(\xi\) follows \(|\xi'' - (1 - 32\kappa^2)|\xi < 8\delta^2\kappa^4\). (Lemma 12). Then we show that \(|\xi|\) will further decrease to less than \(\frac{1}{2}\delta\kappa^4\) before \(a\) decreases to less than \(\kappa^2\), and the trajectory will enter region V from the right (Lemma 13).

- **Stage 2.** After the trajectory enters region V, we will show that it will remain close to the parabola \(\xi \triangleq b^2 - \frac{1}{2}a\kappa - \frac{1}{8}\kappa^4\) that \(|\xi|\) will remain less than \(\frac{1}{8}\delta\kappa^4\) while \(a\) decreases into the interval \(a \in (-\frac{1}{8}(1 - 3\delta\kappa^3), -\frac{1}{8}(1 + 2\delta\kappa^3))\) and the trajectory enters region VI (Lemma 14).

- **Stage 3.** Finally we conclude the proof by a convergence analysis in region VI. The two-step dynamics approximation in region VI is very similar to region III, that the \(ab\kappa\) term in the two-step update of \(b\) will dominate. Since \(a\) is now negative, \(|b|\) will follow the multiplicative update \(|b'| < (1 + a\kappa)|b|\). We will
also show that the movement of $a$ will be small, and the final converging minima will not be far from the extreme point $a = \frac{1}{4} \kappa^3$ (Lemma 15).

**B.3 1 and 2-Step Dynamics of $a$ and $b$**

Now we begin our rigorous analysis on the dynamics of $(a_t, b_t)$.

For simplicity of notations, when analyzing the 1-step and 2-step dynamics of $(a_t, b_t)$, we use $a, a', a''$ to denote $a_t, a_{t+1}, a_{t+2}$ and $b, b', b''$ to denote $b_t, b_{t+1}, b_{t+2}$. For simplicity of calculation, we consider the change of variable $\kappa = \sqrt{\eta}$.

In the following analysis, use operator $\mathcal{O}(\cdot)$ to only hide absolute constants that are independent of $\epsilon, \kappa, a, b$ and no asymptotic limits are taken. Concretely, for monomial $x$ and polynomial $y$ of some variables, we denote $y = \mathcal{O}(x)$ if there exists some absolute constant $K$ independent of the variables such that for any parameterization of the variables, $|y| < K|x|$. Note that this is stronger than the usual big-$O$ notations. Throughout the analysis we will use $K$ to represent the absolute constant that uniformly upper bounds all the absolute constants of the $\mathcal{O}(\cdot)$ terms. This is well defined as we will only be considering finite number of $\mathcal{O}(\cdot)$ terms.

**B.3.1 One Step Dynamics Approximation of $a$ and $b$**

**Lemma 1.** Fix any positive $\epsilon$ that $\epsilon < 0.5$, for any $\kappa \in (0, \epsilon^{\frac{1}{4}})$, for all $(a, b)$ such that $|a| < \epsilon \kappa^{-1}$ and $|b| < \min\{1, \epsilon^{\frac{1}{4}} \kappa^{-2}\}$, we have

$$a' = a - 2b^2 \kappa^3 + \mathcal{O}(eb^2 \kappa^3) + \mathcal{O}(b^2 \kappa^4).$$  

**(Proof of Lemma 1.)** Recall from Eq. (28) that

$$a' = \left(a + (\kappa^{-4} - 4) \frac{1}{2}\right) (1 - b^2(1 + 2b)^2(2 + b)^2 \kappa^4)^{\frac{1}{2}} - (\kappa^{-4} - 4) \frac{1}{2}.$$  

Since $(\kappa^{-4} - 4) \frac{1}{2}$ will approach infinity as $\kappa$ goes to 0, we instead analyze

$$\kappa a' = \left(\kappa a + (1 - 4 \kappa^4) \frac{1}{4}\right) (1 - b^2(1 + 2b)^2(2 + b)^2 \kappa^4)^{\frac{1}{2}} - (1 - 4 \kappa^4) \frac{1}{4}.$$  

Note that $(1 - b^2(1 + 2b)^2(2 + b)^2 \kappa^4)^{\frac{1}{2}}$ will be close to $1 - 2b^2(1 + b)^2(2 + b)^2 \kappa^4$ for not so large $b$ and $1 - 4 \kappa^4$ will be close to 1 for small $\kappa$, we will leverage these two properties to approximate $a'$.

First observe that for any $x \in (0, 8 \epsilon/(1 + 2 \epsilon)^2)$ we have $1 - \frac{\epsilon}{2} - \epsilon x < \sqrt{1 - x} < 1 - \frac{\epsilon}{2}$. Since $\epsilon < 0.5$, $(1 + 2 \epsilon)^2 < 4$, so it is sufficient to let $x < 2 \epsilon$ for the inequality to hold.

Now we substitute $x$ by $b^2(1 + b)^2(2 + b)^2 \kappa^4$. Since $|b| < 1, (1 + b)^2(2 + b)^2 < 36$ Thus when $|b| < \frac{1}{4} \kappa^{-2}$ we have $b^2(1 + b)^2(2 + b)^2 \kappa^4 < 36b^2 \kappa^4 < 36(\frac{1}{4} \kappa^{-2})^2 \kappa^4 < 2 \epsilon$, and therefore

$$\left(1 - b^2(1 + b)^2(2 + b)^2 \kappa^4\right)^{\frac{1}{2}} = 1 - \frac{1}{2} \left(b^2(1 + b)^2(2 + b)^2 \kappa^4\right) + \mathcal{O}(eb^2 \kappa^4)$$

$$= 1 - 2b^2 \kappa^4 + \mathcal{O}(b^2 \kappa^5) + \mathcal{O}(eb^2 \kappa^4).$$  

Since $1 - 4 \kappa^4 > 0$, by Bernoulli inequality we have $(1 - \kappa^4)^{\frac{1}{4}} \geq 1 - 4 \kappa^4$, combining with the requirement of $\kappa < \epsilon^{\frac{1}{4}}$, we have $(1 - \kappa^4)^{\frac{1}{4}} \geq 1 - \kappa^4 > 1 - \epsilon$. Meanwhile since we required $|d| < \epsilon \kappa^{-1}, |sd| < \epsilon$, so

$$(\kappa d + (1 - 4 \kappa^4)^{\frac{1}{4}}) = 1 + \mathcal{O}(\epsilon).$$  

Combining Eq. (33) and Eq. (34) we have

$$\kappa a' = \left(\kappa a + (1 - 4 \kappa^4)^{\frac{1}{4}}\right) (1 - b^2(1 + b)^2(2 + b)^2 \kappa^4)^{\frac{1}{2}} - (1 - 4 \kappa^4)^{\frac{1}{4}}$$

$$= \left(\kappa a + (1 - 4 \kappa^4)^{\frac{1}{4}}\right) (1 - 2b^2 \kappa^4 + \mathcal{O}(b^2 \kappa^5) + \mathcal{O}(eb^2 \kappa^4)) - (1 - 4 \kappa^4)^{\frac{1}{4}}$$

$$= \kappa a \left(1 - 2b^2 \kappa^4 + \mathcal{O}(b^2 \kappa^5) + \mathcal{O}(eb^2 \kappa^4)\right) + \left(1 - 4 \kappa^4\right)^{\frac{1}{4}} \left(-2b^2 \kappa^4 + \mathcal{O}(b^2 \kappa^5) + \mathcal{O}(eb^2 \kappa^4)\right)$$

$$= \kappa a - (1 + \mathcal{O}(\epsilon)) (2b^2 \kappa^4 + \mathcal{O}(b^2 \kappa^5) + \mathcal{O}(eb^2 \kappa^4))$$

$$= \kappa a - 2b^2 \kappa^4 + \mathcal{O}(b^2 \kappa^5) + \mathcal{O}(eb^2 \kappa^4).$$
Dividing both sides by $\kappa$ completes the proof. \hfill $\Box$

**Lemma 2.** For any $\kappa \in (0, 0.1)$, for all $(a, b)$ such that $|a| < \kappa^{-1}$ and $|b| < 1$,
\begin{equation}
    b' = -b - 4ab\kappa - 3b^2 - b^3 + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5).
\end{equation}

**Proof of Lemma 2.** For simplicity of notation, let
\begin{equation}
    \delta \triangleq \sqrt{4\eta^2(1 + b)^2 + \left(a\eta^2 + (1 - 4\eta^2)\right)^2} = \sqrt{4\kappa^2(1 + b)^2 + \left(a\kappa + (1 - 4\kappa^4)\right)^2}.
\end{equation}

Plugging Eq. (37) into Eq. (28), since $|b| < 1$ we have
\begin{equation}
    4b^2\kappa^4 + 16b^3\kappa^4 + 25b^4\kappa^4 + 19b^5\kappa^4 + 7b^6\kappa^4 + b^7\kappa^4 = O(b^2\kappa^4).
\end{equation}

Thus
\begin{equation}
    b' = b - 2b\delta - 3b^2\delta - b^3\delta + 4b^2\kappa^4 + 16b^3\kappa^4 + 25b^4\kappa^4 + 19b^5\kappa^4 + 7b^6\kappa^4 + b^7\kappa^4
\end{equation}
\begin{equation}
    = b - 2b\delta - 3b^2\delta - b^3\delta + O(b^2\kappa^4)
\end{equation}
Thus
\begin{equation}
    b' = b - 2b - 4ab\kappa - 3b^2 - b^3 + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5).
\end{equation}

Combining the conditions required by Lemma 1 and Lemma 2 we have

**Condition B.1** (One-step Dynamics Approximation Condition),
\begin{equation}
    \epsilon < 0.5,
    \kappa < \min\{0.1, \epsilon^{4}\},
    |a| < \epsilon\kappa^{-1},
    |b| < \min\{1, \frac{1}{\epsilon}\kappa^{-2}\}.
\end{equation}

When condition B.1 is satisfied, we have
\begin{equation}
    a' = a - 2b^2\kappa^3 + O(b^2\kappa^3) + O(b^2\kappa^4),
    b' = -b - 4ab\kappa - 3b^2 - b^3 + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5),
\end{equation}

**B.3.2 Two Step Dynamics Approximation of $a$ and $b$**

Now we approximate the 2-step dynamics for $(a, b)$.

**Lemma 3.** Fix some positive constant $\epsilon < 0.1$, with $\kappa$, $a$, $b$ satisfying condition B.1,
\begin{equation}
    b'' = b - 16b^3 + 8ab\kappa + O(b^4) + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5) + O(\epsilon b^2\kappa^3).
\end{equation}

**Proof.** Combining the one step dynamics characterized in Lemma 1 and Lemma 2 we have
\begin{equation}
    b'' = -b' - 4a'b' - 3b^2 - b^3 + O(a^2b\kappa^2) + O(a'b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5).
\end{equation}

We will analyze these terms one by one.
\begin{equation}
    a'b' = \kappa \left(a - 2b^2\kappa^3 + O(eb^2\kappa^3) + O(b^2\kappa^4)\right) \left(-b - 4ab\kappa - 3b^2 - b^3 + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5)\right)
\end{equation}
\begin{equation}
    = \kappa \left(-b - 4ab\kappa - 3b^2 - b^3 + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5)\right)
    - 2b^2\kappa^4 \left(-b - 4ab\kappa - 3b^2 - b^3 + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5)\right)
    + O(ab^2\kappa) + O(b^2\kappa^4)
\end{equation}
\begin{equation}
    = -ab\kappa + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5) + O(\epsilon b^2\kappa^3),
\end{equation}

\[ \]
Lemma 4.

Combining Lemma 1 and Lemma 2 we have

\[ b'' = (-b - 4ab\epsilon - 3b^2 - b^3 + \Omega(ab^2\epsilon) + \Omega(a^2b\epsilon^2) + \Omega(b^2\epsilon^2) + \Omega(b\epsilon^3)) \]

\[ = b (c - 4ab - 3b - b^2) + \Omega(ab^2\epsilon) + \Omega(a^2b\epsilon^2) + \Omega(b^2\epsilon^2) + \Omega(b\epsilon^3) \]

\[ = (-b - 4ab\epsilon - 3b^2 - b^3)^2 + \Omega(b^3\epsilon^2) + \Omega(a^2b^2\epsilon^2) + \Omega(b^3\epsilon^2) + \Omega(b^2\epsilon^3) \]

\[ = b^2 + 6b^3 + O(b^4) + O(a^2b^2\epsilon) + O(b^2\epsilon^4) + O(b\epsilon^5). \quad (47) \]

Hence the last three terms of Eq. (53) can be calculated that

\[ \Omega(b^3\epsilon^2) + \Omega(a^2b^2\epsilon^2) + \Omega(b^3\epsilon^2) + \Omega(b^2\epsilon^3) \]

\[ \Omega(b^2\epsilon^4) = \Omega(b^2\epsilon^4) \]

\[ \Omega(b^2\epsilon^5) = \Omega(b^2\epsilon^5) \]

Note that \( b' = O(b) + O(ab\epsilon) \) and \( a' = a + O(b^2\epsilon^3) \), so

\[ O(a'b^2\epsilon) = O(ab^2\epsilon) + O(b^3\epsilon^4), \]

\[ O(a^2b^2\epsilon^2) = O(a^2b\epsilon^2) + O(a^2b^2\epsilon^2), \]

\[ O(b^2\epsilon^4) = O(b^2\epsilon^4) + O(ab^2\epsilon^3), \]

\[ O(b') = O(b) + O(ab\epsilon). \quad (49) \]

Hence

\[ O(b^2a') + O(b^2a') + O(b^2\epsilon^4) + O(b^2\epsilon^4) = O(ab^2\epsilon) + O(a^2b\epsilon^2) + O(b^2\epsilon^4) + O(b\epsilon^5). \quad (50) \]

Combining above we have

\[ b'' = (-b - 4ab\epsilon - 3b^2 - b^3)^2 - 4(-ab\epsilon) - 3(b^2 + 6b^3) - (-b^3) + O(b^4) + O(ab^2\epsilon) + O(a^2b\epsilon^2) + O(b^2\epsilon^4) + O(b\epsilon^5) \]

\[ = b + 8ab\epsilon - 16b^3 + O(b^4) + O(ab\epsilon) + O(a^2b\epsilon^2) + O(b^2\epsilon^4) + O(b^3\epsilon^5) + O(ab^2\epsilon^3). \quad (51) \]

Lemma 4. Fix some positive constant \( \epsilon < 0.5 \), with \( \kappa, a, b \) satisfying condition B.1,

\[ a'' = a - 4b^2\kappa^4 + O(b^2\kappa^3) + O(b^2\kappa^4). \quad (52) \]

Proof of Lemma 4. Combining Lemma 1 and Lemma 2 we have

\[ a'' = a' - 2b^2\kappa^3 + O(b^2\kappa^3) + O(b^2\kappa^4). \quad (53) \]

From Eq. (47) in the proof of Lemma 3 we have

\[ b'' = b^2 + O(b^3) + O(a^2b^2\epsilon^2) + O(b^3\epsilon^4) + O(b^2\epsilon^5). \quad (54) \]

Hence the last three terms of Eq. (53) can be calculated that

\[ b^2\kappa^3 = b^2\kappa^3 + O(b^3\epsilon^3) + O(a^2b^2\epsilon^2) + O(b^3\epsilon^4) + O(b^2\epsilon^5), \]

\[ O(b^2\epsilon^4) = O(b^2\epsilon^4) \]

\[ O(b^2\epsilon^5) = O(b^2\epsilon^5) \]

\[ \Omega(b^2\epsilon^4) = \Omega(b^2\epsilon^4) + O(b^3\kappa^4) + O(a^2b^2\kappa^5) + O(b^3\kappa^5) + O(b^2\kappa^6), \quad (55) \]

\[ O(b^2\epsilon^5) = O(b^2\epsilon^5) + O(b^3\kappa^4) + O(a^2b^2\kappa^5) + O(b^3\kappa^5) + O(b^2\kappa^6), \quad (57) \]
Combining above we have that
\begin{align*}
    a'' &= a' - 2b^2\kappa^3 + O(ab^2\kappa^3) + O(b^2\kappa^4) \\
    &= a - 2b^2\kappa^3 + O(ab^2\kappa^3) + O(b^2\kappa^4) - 2b^2\kappa^3 \\
    &\quad + O(b^2\kappa^3) + O(ab^2\kappa^3) + O(b^2\kappa^3) + O(2ab^2\kappa^3) + O(b^2\kappa^5) \\
    &\quad + O(ab^2\kappa^3) + O(b^2\kappa^4) + O(ab^2\kappa^3) + O(b^2\kappa^3) \\
    &= a - 4b^2\kappa^3 + O(ab^2\kappa^3) + O(b^2\kappa^3) + O(b^2\kappa^4).
\end{align*}

This completes the proof.

Combining Lemma 4 and Lemma 3, the 2-step dynamics approximation can be summarized as:

**Corollary B.1.** For any positive constant \( \epsilon < 0.5 \), with \( \kappa, a, b \) satisfying condition B.1 we have
\begin{align*}
    b'' &= b - 16b^3 + 8ab\kappa + O(b^4) + O(ab^2\kappa) + O(a^2b\kappa^2) + O(b^2\kappa^4) + O(b\kappa^5) + O(ab^2\kappa^3), \\
    a'' &= a - 4b^2\kappa^3 + O(ab^2\kappa^3) + O(b^2\kappa^3) + O(b^2\kappa^4).
\end{align*}

**B.4 Phase I: Convergence to Near Parabola**

Now we show that under the \((a, b)\) parameterization, any initialization \((a_0, b_0)\) such that \(a_0 \in (3\kappa^2, \frac{1}{3}K^{-2}\kappa^{-1})\) and \(b_0 \in (-K^{-1}, K^{-1})\) will converge near the parabola very fast. As mentioned above, there are mainly three regimes of interest. We will first determine the region in which the two step update \(a'' - b\) is solely dominated by \(-4b^2\kappa^3\) or \(ab\kappa\).

To formally analyze the different dynamics and characterize the regimes for them, in this section we use \( K \) to denote the uniform upper bound over the absolute constants hidden by the \( O(\cdot) \) operator in the 2-step dynamics approximation characterized by Corollary B.1. Since there is only finite terms with \( O \)-notation, such constant \( K \) is well defined and independent of \( \epsilon, \kappa, a, b \). Without loss of generality we assume \( K > 512 \).

Rewriting Corollary B.1 with the uniform upper bound \( K \), we have the following corollary:

**Corollary B.2. (2-step dynamics approximation of \( a \) and \( b \))** There exists some absolute constants \( K \) such that for any constant \( \epsilon < 0.5 \), for all \( \kappa, a, b \) satisfying condition B.1, the 2-step update of \((a, b)\) can be characterized by
\begin{equation}
    a'' = a - 4b^2\kappa^3 + R_a, \quad b'' = b - 16b^3 + 8ab\kappa + R_b,
\end{equation}
where the remainder \( R_a \) and \( R_b \) have upper bound:
\begin{align*}
    |R_a| &< K \left| c^2\kappa^3 \right| + K \left| c^3\kappa^3 \right| + K \left| c^2\kappa^3 \right|, \\
    |R_b| &< K \left| c^4 \right| + K \left| c^2d\kappa \right| + K \left| cd^2\kappa^2 \right| + K \left| c^2\kappa^4 \right| + K \left| c\kappa^5 \right| + K \left| c^2\kappa^3 \right|.
\end{align*}

Now we establish the conditions to characterize the work zones in order for the analysis to be more tractable in different regimes.

**B.4.1 When \( a'' - a \) is close to \(-4b^2\kappa^3\)**

Here we formalize the observation that when \( b \) and \( \kappa \) are not large, the two-step movement of \( a \) is monotone and always close to \( 4b^2\kappa^3 \). Concretely we have the following lemma:

**Lemma 5.** Fix \( \epsilon = K^{-1} \), for all \( \kappa, a, b \) satisfying condition B.1 as well as the extra condition of \(|\kappa| < K^{-1} \) and \(|b| < K^{-1} \), we have \( |a'' - (a - 4b^2\kappa^3)| < 3b^2\kappa^3 \).

**Proof of Lemma 5.** Since we assume \( K > 512 \), we have \( \epsilon = K^{-1} < 0.5 \) as required by Corollary B.2. Since \( \kappa, a, b \) satisfies condition B.1, by Corollary B.2 we have \( a'' = a - 4b^2\kappa^3 + R_a \) where
\begin{equation}
    |R_a| < K \left| eb^2\kappa^3 \right| + K \left| b^2\kappa^3 \right| + K \left| b^2\kappa^4 \right|.
\end{equation}
Thus to prove the lemma we only need to bound every term on RHS of Eq. (62) by \( b^2\kappa^3 \).

(i) Since we fixed \( \epsilon = K^{-1} \), \( K \left| eb^2\kappa^3 \right| = b^2\kappa^3 \).
(ii) Since \( |b| < K^{-1}, K |b^3| < K |K^{-1}b^2| < b^2 \).

(iii) Since \( \kappa < K^{-1}, K |b^2\kappa^3| < K |K^{-1}b^2\kappa^3| < b^2\kappa^3 \).

Therefore \( |R_a| < 3b^2\kappa^3 \) which completes the proof. \( \square \)

Note that when we fix \( \epsilon = K^{-1} \), condition B.1 becomes

\[
\kappa < \min\{0.1, K^{-\frac{1}{2}}\}, \quad |a| < K^{-1}K^{-1}, \quad |b| < \min\{1, \frac{1}{2}K^{-1}K^{-2}\}. \tag{63}
\]

Combining with the additional condition of Lemma 5, we can summarize the condition for Lemma 5 to hold as

\[
\begin{align*}
\kappa &< \min\{0.1, K^{-\frac{1}{2}}, K^{-1}\}, \quad (1) \\
|a| &< K^{-1}K^{-1}, \quad (2) \\
|b| &< \min\{1, K^{-1}, \frac{1}{2}K^{-1}K^{-2}\}. \quad (3)
\end{align*}
\]

With \( K > 512 \), \( K^{-1} < 0.1 \), so (1) can be reduced to \( \kappa < K^{-1} \). Since \( \kappa < K^{-1}, \frac{1}{2}K^{-2} > \frac{1}{5}K \), so \( \frac{1}{5}K^{-1}K^{-2} > \frac{1}{5}K > 1 > K^{-1} \), and thus (3) can be reduced to \( |b| < K^{-1} \). In conclusion, the following condition is sufficient for \( |a'' - (a - 4b^2\kappa^3)| < 3b^2\kappa^3 \).

**Condition B.2** (Condition for \((a \pm 3)b^2\kappa^3\) movement of \(a\)),

\[
\kappa < K^{-1}, \quad |a| < K^{-1}K^{-1}, \quad |b| < K^{-1}. \tag{65}
\]

### B.4.2 When \(-b^3\) Dominates the Dynamics of \(b\)

**Lemma 6.** For all \(\kappa, a, b\) satisfying

\[
\begin{align*}
\kappa &< K^{-1}, \\
|a| &< (\kappa^3, K^{-2}K^{-1}), \\
|b| &< (\sqrt{|a|\kappa}, K^{-1}).
\end{align*}
\]

We have \( |b'' - (b - 16b^3)| \leq 14|b^3| \).

**Proof of Lemma 6.** First it is straightforward to check that the condition on \(\kappa, a, b\) is stronger than condition B.1 if we set \(\epsilon = 0.1\), thus by Corollary B.2 we have \(b'' = b - 16b^3 + 8abc + R_b\) where

\[
|R_b| < K |b^4| + K |ab^2\kappa| + K |a^2b_2^2\kappa^3| + K |b^2\kappa^4| + K |bc_3^5| + K |\epsilon b^2\kappa^3|. \tag{67}
\]

Thus to prove the claim, it is sufficient to bound \(|8abc|\) by \(8|b^3|\) and every term on RHS of Eq. (67) by \(|b^3|\). We will now bound them term by term.

(i) Since \( \sqrt{|a|\kappa} < |b|, |a\kappa| < b^2 \), so \(8|abc| = 8|b||a\kappa| < 8|b^3| \).

(ii) Since \( |b| < K^{-1} \), \(K|\kappa^4| < K|K^{-1}b^4| = |b^3| \).

(iii) Since \( |a| < K^{-2}K^{-1} \), multiplying \(K^2|ax^2|\) on both side gives \(K^2a^2\kappa^2 < |a\kappa|\). It follows by taking square root that \(K|a\kappa^2| < \sqrt{|a|\kappa}\). Since \( |b| > \sqrt{|a|\kappa} \), we have \(K|a\kappa| < |b| \). Multiply \(b^2\) on both side gives \(K|ab^2\kappa^3| < |b^3| \).

(iv) Since \( |a| < K^{-2}K^{-1} < K^{-1}K^{-1} \), multiply \(K|a\kappa|\) on both side gives \(K\kappa a^2\kappa^2 < |a\kappa|\) and hence \(\sqrt{K}|a\kappa| < \sqrt{|a|\kappa} < |b| \). Squaring both sides and multiply by \(b\) gives \(K|a^2b^2\kappa^2| < |b^3| \).

(v) Since \( |a| > \kappa^3 \) and \( |b| > \sqrt{|a|\kappa} \), we have \( |b| > \kappa^2 > K\kappa^4 \). Multiplying \(b^2\) on both sides, we have \(K|b^2\kappa^4| < |b^3| \).

(vi) In (v) we observe that \( |b| > \kappa^2 \), so \( |b| > \sqrt{K}\kappa^2 \) and hence \(b^2 > K\kappa^5 \). Multiplying \(|b|\) on both sides gives \(K|bc_3^5| < |b^3| \).
(vii) Since we fixed \( \varepsilon = 0.1 \) while \( \kappa < K^{-1} < 0.1 \), we have \( \varepsilon \kappa < 1 \). Since \( |b| > \kappa^2 \), we have \( |b| > \kappa^3 \varepsilon > K\varepsilon \kappa^3 \).

Therefore we have \(|8abc| + |R_b| < 14|c^3|\), which completes the proof.

We restate the sufficient condition for \(|b'' - (b - 16b^3)| \leq 14|b^3|\) as follow

**Condition B.3** (Condition for \(-b^3\) Dominated by \(b^3\)).

\[
\kappa < K^{-1},
\]

\[
|a| \in (\kappa^3, K^{-2}\kappa^{-1}),
\]

\[
|b| \in (\sqrt{|a|\kappa}, K^{-1}).
\]  

(68)

**B.4.3 When \(abc\) Dominates the \(b'' - b\)**

**Lemma 7.** For any \(\kappa, a, b\) satisfying

\[
\kappa < K^{-1},
\]

\[
|a| \in (\kappa^3, K^{-2}\kappa^{-1}),
\]

\[
|b| < \min\{\frac{1}{2\sqrt{2}}|a|\kappa, K^{-1}\}.
\]  

(69)

We have \(|b'' - (b + 8abc)| \leq 7|abc|\).

**Proof of Lemma 7.** First fix \( \varepsilon = 0.5 \). It is straightforward to check that for all \( \kappa, a, b\) satisfying the given condition, condition **B.1** is also satisfied, so by Corollary **B.2** we have \(b'' = b - 16b^3 + 8abc + R_b\) where

\[
|R_b| < K|b^4| + K|ab^2\kappa| + K|a^2bc^2| + K|b^7\kappa^4| + K|bc^5| + K|eb^2\kappa^3|.
\]  

(70)

Thus to prove the claim, it is sufficient to bound \(16|b^3|\) by \(2|abc|\), two terms in RHS of Eq. (70) by \(\frac{1}{2}|b^3|\) and the remaining 4 terms by \(|b^3|\). We will now bound them term by term.

(i) Since \( |b| < \frac{1}{2\sqrt{2}}\sqrt{|a|\kappa}, b^2 < \frac{1}{8}|a|\kappa \). Multiply 16|b| on both side gives 16|b^3| < 2|abc|.

(ii) Since \( |a| < K^{-2}\kappa \), we have \( |a|\kappa < K^{-2} \). Multiplying \(a^2\kappa^2\) on both side gives \( |a^3|\kappa^3 < K^{-2}a^2\kappa^3 \). If we take the 6-th root, we have \( \sqrt[6]{|a|\kappa} < (K^{-1}|a|\kappa)^{\frac{1}{3}} \). Since \(|b| < \sqrt[6]{|a|\kappa}, |b| < (K^{-1}|a|\kappa)^{\frac{1}{3}} \) and hence \(|b^3| < K^{-1}|a|\kappa \). Multiply \(K|b|\) on both side gives \(K|b^4| < |abc|\).

(iii) Since \( |b| < K^{-1} \), multiply both side by \(K|abc|\) gives \(K|ab^2\kappa| < |abc|\).

(iv) Since \( |a| < K^{-2}\kappa^{-1} < \frac{1}{2}K^{-1}\kappa^{-1} \) (as we assumed \( K > 512 \)), multiply both side by \(|ab|\kappa^2\) gives \(K|a^2bc^2| < \frac{1}{2}|abc|\).

(v) Since \( |a| > \kappa^3 \) and \( \kappa < K^{-1} \), we have \( |a| > \kappa^3 > K^{-2}\kappa^5 > K^2\kappa^7 \). Multiplying \(K^{-2}|a|\kappa^{-6}\) on both side gives \(K^{-2}a^2\kappa^{-6} > |a|\kappa \). It follows by taking the square root that \( \sqrt{|a|\kappa} < K^{-1}|a|\kappa^{-3} \). Since we have \(|b| < \frac{1}{2\sqrt{2}}\sqrt{|a|\kappa} < \frac{1}{2}\sqrt{|a|\kappa} \), combining with above gives \(|b| < \frac{1}{2}K^{-1}|a|\kappa^{-3} \). Multiply \(K|b|\kappa^4\) on both side gives \(K|b^7\kappa^4| < \frac{1}{2}|abc|\).

(vi) Since \( |a| > \kappa^3 \), we have \( |a| > K\kappa^4 \). Multiplying \(|b|\kappa|\) on both side gives \(K|bc^5| < |abc|\).

(vii) Since \( |a| > \kappa^3 \) and \( \epsilon = 0.5 \), we have \( |a| > K^2\epsilon^2\kappa^5 \). Taking the multiplicative inverse and multiply \(a_2\kappa\) on both side gives \(|a|\kappa < K^{-2}\epsilon^2\kappa^{-6}a^2\kappa^2 \). It follows by taking the square root that \( \sqrt{|a|\kappa} < K^{-1}\epsilon^{-1}\kappa^{-3}|a| \). Finally multiply \(Ke|b|\kappa^5\) on both side, we have \(K|eb^2\kappa^3| < |abc|\).

From (i) we have \(16|b^3| < 2|abc|\), from (ii) - (vii) we have \(R_b = K|b^4| + K|ab^2\kappa| + K|a^2bc^2| + K|b^7\kappa^4| + K|bc^5| + K|eb^2\kappa^3| < 5|abc|\). Therefore \(|b'' - (b + 8abc)| \leq 16|b^3| + R_b \leq 7|abc|\), which completes the proof.

We restate the sufficient condition for \(|b'' - (b + 8abc)| \leq 7|abc|\) as follow:
By the strong inductive hypothesis, these properties also holds when substituting $k$.

Under the assumption that notation to let $(c_t, d_t)$ denote $c$ and $d$ after the $t$-th 2-step update with step size $\eta = \kappa^2$ from the initialization $(c_0, d_0)$.

**Theorem B.4** (Condition for ab Dominated $b^3 - b$ Movement).

\[
\begin{align*}
\kappa &< K^{-1}, \\
|a| &\in (\kappa^3, K^{-2}\kappa^{-1}), \\
|b| &< \min\{\frac{1}{2}\sqrt{a|\kappa, K^{-1}}\}.
\end{align*}
\]

**B.4.4 Convergence when $-b^3$ dominates ab**

Now we are ready to analyze the dynamics when $c^3$ dominates the movement of $c$. For $t \in \mathbb{N}$, we abuse the notation to let $(c_t, d_t)$ denote $c$ and $d$ after the $t$-th 2-step update with step size $\eta = \kappa^2$ from the initialization $(c_0, d_0)$.

**Lemma 8** (Convergence to near parabola from large $b$). For any $\kappa < K^{-1}$, for any initialization $(a_0, b_0)$ satisfying $a_0 \in (12\kappa^2, 12K^{-2}\kappa^{-1})$ and $|b_0| \in [2\sqrt{|a_0|\kappa, K^{-1}})$, there exists some $T < \kappa^{-4}$ such that $a_T \in (2\kappa^2, K^{-2}\kappa^{-1})$ and $|b_T| \in (\sqrt{aTK}, 2\sqrt{aTK})$.

**Proof of Lemma 8.** We will prove the claim using induction.

Consider the inductive hypothesis for $k \in \{0, 1, \ldots, [\kappa^{-4}]\}$ that

\[
P(k): |a_k| \in (2\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1}) \quad \text{and} \quad |b_k| \in (2\sqrt{a_k}\kappa, \min\{K^{-1}, (k + 1)^{-\frac{3}{2}}\}).
\]

Since $|b_0| < K^{-1} < 1 = (0 + 1)^{-\frac{3}{2}}$ and $a_0 \in (3\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1}) \subset (2\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1})$ as required by the initialization, the base case $P(0)$ holds trivially. Now we can proceed to the inductive step.

Assume $P(l)$ holds for all $l \leq k$, we want to show that $P(k + 1)$ holds unless $|b_{k+1}| < 2\sqrt{|a_{k+1}|\kappa}$.

By the inductive hypothesis, $(a_k, b_k)$ satisfies condition B.2 and condition B.3. Thus by Lemma 5 and Lemma 6 we have

\[
a_{k+1} = (a_k - 7b_k^2\kappa^3, a_k - b_k^2\kappa^3), \quad |b_{k+1}| \in (|b_k| - 30|b_k|, |b_k| - 2|b_k|).
\]

By the strong inductive hypothesis, these properties also holds when substituting $k$ by any $l < k$.

We first check the lower bound for $a_{k+1}$ under the assumption that $k < \kappa^{-4}$. Since $a_{l+1} > a_l - 7b_l^2\kappa^3$ for all $l \leq k$, we have

\[
a_{k+1} > a_0 - \sum_{l=0}^{k} 7b_l^2\kappa^3
\]

\[
> a_0 - \sum_{l=0}^{k} 7 \left( (l + 1)^{-\frac{3}{2}} \right)^2 \kappa^3 \quad \text{(Since } b_l < (l + 1)^{-\frac{3}{2}} \text{ by IH)}
\]

\[
> 12\kappa^2 - 7\kappa^3 \sum_{l=0}^{k} \frac{1}{l + 1}
\]

\[
> 12\kappa^2 - 7\kappa^3 \left( 1 + \int_{1}^{k+1} \frac{1}{\tau} d\tau \right)
\]

\[
= 12\kappa^2 - 7\kappa^3(1 + \log(k + 1)).
\]

Under the assumption that $k < \kappa^{-4}$ and $\kappa < K^{-1} < \frac{1}{2\kappa^2}$, it is not hard to check that

\[
1 + \log(k + 1) < 2 + \log(\kappa^{-4}) = 2 - 4\log(\kappa) < \frac{10}{\kappa}. \quad \text{(74)}
\]

The last inequality holds since when $\kappa = \frac{1}{2\kappa^2}$ we have $2 - 4\log(\frac{1}{\kappa^2}) = 2 - 4\log(\kappa) = \frac{10}{\kappa}$, PLugging back into Eq. (73), we know that if $P(l)$ holds for all $l \leq k$ and $k < \kappa^{-4}$, then

\[
a_k + 1 > 12\kappa^2 - 7\kappa^3 \left( \frac{10}{\tau} \kappa^{-\frac{1}{2}} \right) = 12\kappa^2 - 10\kappa^3 = 2\kappa^2. \quad \text{(75)}
\]

The upper bound of $a_k < \frac{1}{2}K^{-2}\kappa^{-1}$ always holds since $a$ is monotonically decreasing by Eq. (72).
Now we check the upper bound for \(|b_{k+1}|\). Consider \(f(x) = x^{-\frac{3}{2}}\), we have \(f'(x) = -\frac{3}{2}x^{-\frac{5}{2}} = -\frac{3}{2}f(x)^{\frac{3}{2}}\) and \(f''(x) = \frac{9}{4}x^{-\frac{7}{2}}\). Note that \(f''(x) > 0\) for all \(x > 0\), so by a first order Taylor expansion around \(x = k + 1\) we have \(f(k + 2) > f(k + 1) - \frac{9}{8}f(k + 1)^{\frac{3}{2}}\). Combined with \(|b_{k+1}| < |b_k| - |b_k^3|\), it follows
\[
\begin{align*}
f(k + 2) - |b_{k+1}| &\geq f(k + 1) - \frac{1}{2}f(k + 1)^{\frac{3}{2}} |b_k| + |b_k^3| \\
&= (f(k + 1) - |b_k|) - \frac{1}{2}(f(k + 1)^{\frac{3}{2}} - |b_k^3|) + \frac{1}{2}b_k^3 \\
&\geq (f(k + 1) - |b_k|) - \frac{1}{2}(f(k + 1) - |b_k|)(|b_k^3| + |b_k|f(k + 1) + f(k + 1)^{\frac{3}{2}}) \\
&= (f(k + 1) - |b_k|) \left(1 - \frac{1}{2}(|b_k^3| + |b_k|f(k + 1) + f(k + 1)^{\frac{3}{2}})\right).
\end{align*}
\] (76)

Since \(f(k + 1) \leq 1\) and \(|b_k| < |b_0| < K^{-1} < \frac{1}{2}\), for all \(k \geq 1\), we have \(b_k^3 + |b_k|f(k + 1) + f(k + 1)^{\frac{3}{2}} < 2\), and hence \((1 - \frac{1}{2}(|b_k^3| + |b_k|f(k + 1) + f(k + 1)^{\frac{3}{2}})) > 0\). Since \(|b_k| < (k + 1)^{-\frac{3}{2}} = f(k + 1)\) by the induction hypothesis, we have \(f(k + 2) - |b_{k+1}| > 0\), so \(|b_{k+1}| < (k + 2)^{-\frac{3}{2}}\). The other upper bound \(|b_{k+1}| < K^{-1}\) holds trivially since \(|b_0| < K^{-1}\) as required by the initialization and \(|b_k|\) is monotonically decreasing according to Eq. (72).

Now we will show that there exists some \(\tau < \kappa^{-4}\) that \(|b_0| < 2\sqrt{\frac{\tau}{\kappa}}\). Assume toward contradiction that there is no such \(\tau\), then the induction may proceed to \(h \triangleq \kappa^{-4}\) so that \(a_h > 2\kappa^2\), \(|b_h| < (h + 1)^{-\frac{3}{2}} \triangleq \kappa^{-4}\) \(\frac{3}{2} \triangleq \kappa^2\) and \(|b_h| > 2\sqrt{\frac{\tau}{\kappa}} = 2\sqrt{2}\kappa^2\). The last two inequalities lead to contradiction as \(2\sqrt{2}\kappa^2 > \kappa^2\), so the assumption does not hold and there exists some \(\tau < \kappa^{-4}\) for \(|b_0| < 2\sqrt{\frac{\tau}{\kappa}}\).

Let \(T < [\kappa^{-4}]\) be the smallest such \(\tau\), then the induction may proceed to \(k = T - 1\), which guarantees \(P(t)\) for all \(t < T\). Thus for all \(t < T\), \(a_t > (2\kappa^2, K^{-2}\kappa^{-1})\) and \(|b_t| \in (2\sqrt{\frac{\tau}{\kappa}}, K^{-1})\). Since \(P(T - 1)\) holds, following Eq. (73) we also have \(a_T > 2\kappa^2\).

Now we still need to show \(|b_T| > \sqrt{\frac{\tau}{\kappa}}\). Since \(a_k\) is monotonically decreasing, it is sufficient to show \(|b_T| > \sqrt{\frac{\tau}{\kappa} = \sqrt{\frac{\tau}{\kappa}}\kappa}\). From Eq. (72) we have \(|b_T| > |b_{T-1}| - 30|b_{T-1}^2| = |b_{T-1}|(1 - 30b_{T-1}^2). Since \(b_{T-1} < K^{-1} < \frac{1}{2\kappa^2}\), \((1 - 30b_{T-1}^2) > \frac{1}{2}\). Combined with \(|b_{T-1}| > \sqrt{\frac{\tau}{\kappa} = \frac{1}{2}}\) as shown above, we have \(|b_T| > \frac{1}{2}(\sqrt{\frac{\tau}{\kappa}} = \sqrt{\frac{\tau}{\kappa}}\kappa\), which completes the proof. \(\Box\)

### B.4.5 Convergence when \(a\) dominates \(b^3\)

**Lemma 9** (Convergence to near parabola from small \(a\)). For any \(\kappa < K^{-1}\), for any initialization \((a_0, b_0)\) satisfying \(a_0 \in (12\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1})\) and \(|b_0| \in (0, \frac{1}{4}\sqrt{\frac{\tau}{\kappa}}\kappa)\), there exists some \(T < \frac{1}{2}\log(|b_0|^{-1})\kappa^{-\frac{3}{2}}\) such that \(|b_T| \in (\frac{1}{4}\sqrt{\frac{\tau}{\kappa}}\kappa, \frac{1}{4}\sqrt{\frac{\tau}{\kappa}}\kappa)\) and \(a_T \in (2\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1})\).

**Proof of Lemma 9.** We will prove this claim using induction.

Consider the inductive hypothesis for \(k \in \mathbb{N}\) that
\[
P(k) : |b_k| \in (|b_0|(1 + 4\kappa^2)^k, \frac{1}{4}\sqrt{\frac{\tau}{\kappa}}\kappa), a_0 \in (2\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1})
\]
and if \(k \geq 1\), \(|(b_k - |b_0|)/(a_0 - a_k)| > \kappa^{-\frac{3}{2}}\).

The base case when \(k = 0\) holds from the initialization, so we proceed to the inductive step. Assume \(P(l)\) holds for all \(l \leq k\), we want to show \(P(k + 1)\) holds unless \(|b_k| > \frac{1}{4}\sqrt{\frac{\tau}{\kappa}}\kappa\).

First note that by the inductive hypothesis, since \(a_k < \frac{1}{4}K^{-2}\kappa^{-1}\), we have \(|b_k| < \frac{1}{4}\sqrt{\frac{\tau}{\kappa}}\kappa < \frac{1}{4}\sqrt{\frac{\tau}{\kappa}K^{-2}\kappa^{-1}} < K^{-1}\). Combining with conditions on \(|a_k|\) and \(|b_k|\) from the inductive hypothesis we have \((a_k, b_k)\) satisfying condition B.2 and condition B.4. Thus by Lemma 5 and Lemma 7 we have
\[
a_{k+1} \in (a_k - 7b_k^2\kappa^3, a_k - b_k^2\kappa^3), \quad |b_{k+1}| \in (|b_k| + 2|a_kb_k\kappa|, |b_k| + 14|a_kb_k\kappa|).
\] (77)

Observe that when \(a\) is not too small, the movement of \(b\) is significantly larger than the movement of \(a\). From
Eq. (77) we have \( a_k - a_{k+1} < 8b_k^2\kappa^3 \) and \( |b_{k+1} - b_k| > 2a_k|b_k|\kappa \), so
\[
\frac{|b_{k+1} - b_k|}{a_k - a_{k+1}} > \frac{2a_k|b_k|\kappa}{8b_k^2\kappa^3} = \frac{1}{4} \frac{a_k}{|b_k| 4\kappa^2} > \frac{1}{4} \frac{\sqrt{a_k}}{\kappa \sqrt{2}} \quad \text{(since } |b| < \frac{1}{4} \sqrt{a_k\kappa}) \quad (78)
\]
\[
= \frac{\sqrt{\kappa}}{\kappa^2} > \kappa^{-\frac{3}{2}}. \quad \text{(since } a_k > \kappa^2) \quad (78)
\]

When \( k = 0 \), we directly have \( (|b| - |b_0|)/(a_0 - a_1) > \kappa^{-\frac{3}{2}} \). When \( k \geq 1 \), from the inductive hypothesis we have \( (|b_k| - |b_0|)/(a_0 - a_k) > \kappa^{-\frac{3}{2}} \), combining with \( (|b_{k+1} - b_k|)/(a_k - a_{k+1}) > \kappa^{-\frac{3}{2}} \), we have \( (|b_{k+1} - b_k|)/(a_0 - a_{k+1}) > \kappa^{-\frac{3}{2}} \) by the mediant inequality.

Now we check the bounds on \( |a_{k+1}| \) and \( |b_{k+1}| \).

Since \( a \) is monotonically decreasing from Eq. (77), we have \( a_{k+1} < a_0 < \frac{1}{4} K^{-2}\kappa^{-1} \).

Since \( (|b_k| - |b_0|)/(a_0 - a_k) > \kappa^{-\frac{3}{2}} \) according to the inductive hypothesis and \( (a_0 - a_k) > 0 \) by monotonicity of \( a \), \( a_0 - a_k < |(b_k| - |b_0|)\kappa^{-\frac{3}{2}} < |b_k|\kappa^{-\frac{3}{2}} < \frac{1}{4} \sqrt{a_k\kappa} \kappa^{-\frac{3}{2}} < \frac{1}{4} \sqrt{a_0\kappa} \kappa^{-\frac{3}{2}} \). Here the last step holds again by monotonicity of \( a \). Reorganizing the inequality we have \( a_k > a_0 - \frac{1}{4} \sqrt{a_0\kappa} \kappa^{-\frac{3}{2}} = \sqrt{a_0}(\sqrt{a_0} - \frac{1}{4} \kappa^{-\frac{3}{2}}) \). Since \( a_0 > 12\kappa^{-\frac{3}{2}} \) by the initialization condition, \( \sqrt{a_0} > 3\kappa^{-\frac{3}{2}} \) and \( \sqrt{a_0} - \frac{1}{4} \kappa^{-\frac{3}{2}} > 2\kappa^{-\frac{3}{2}} \). Thus \( a_k > \sqrt{a_0} (\sqrt{a_0} - \frac{1}{4} \kappa^{-\frac{3}{2}}) > 6\kappa^{-\frac{3}{2}} \). Note that since \( |b_k| < K^{-1} - \frac{1}{\kappa^{\frac{3}{2}}} \), \( 7\kappa^2 \kappa^3 < 7K^{-2}\kappa^3 < \kappa^3 \). From Eq. (77) we have \( a_{k+1} > a_k > 8b_k^2\kappa^3 > 6\kappa^{-\frac{3}{2}} - \kappa^{-3} > 2\kappa^{-\frac{3}{2}} \). This gives the desired lower bound for \( a_{k+1} \).

Since \( |b_{k+1}| = |b_k| + 2a_k|b_k|\kappa \) from Eq. (77), combining with \( a_k > 2\kappa^{-\frac{3}{2}} \) we have \( |b_{k+1}| > |b_k|(1 + 2a_k\kappa) > |b_k|(1 + 4\kappa^{-\frac{3}{2}}) \). Since \( |b_k| > |b_0|(1 + 4\kappa^{-\frac{3}{2}}) \) by the inductive hypothesis, we have \( |b_{k+1}| > |b_0|(1 + 4\kappa^{-\frac{3}{2}})^{k+1} \).

With the guarantees on \( |a_{k+1}| \), \( |b_{k+1}| \), and \( (|b_k| - |b_0|)/(a_0 - a_k) \) as shown above, if we additionally assume that \( |b_{k+1}| < \frac{1}{4} \sqrt{a_k\kappa} \kappa^{-\frac{3}{2}} \), \( P(k + 1) \) will hold and the induction can proceed.

Now claim that there exists some \( \tau < \frac{1}{4} \log(|b_0|^{-1}) \kappa^{-\frac{3}{2}} \) such that \( |b_T| > \frac{1}{4} \sqrt{a_T\kappa} \kappa^{-\frac{3}{2}} \). Assume toward contradiction that there is no such \( \tau \), then the induction can proceed for any \( t \in \mathbb{N} \).

Consider \( t \geq \frac{1}{4} \log(|b_0|^{-1}) \kappa^{-\frac{3}{2}} \), we have
\begin{align*}
t & \geq \log(|b_0|^{-1})(\frac{1}{4} \kappa^{-\frac{3}{2}} + \frac{1}{4} \kappa^{-\frac{3}{2}}) \\
& > \log(|b_0|^{-1})(1 + \frac{1}{4} \kappa^{-\frac{3}{2}}) \quad \text{(Since } \kappa^{-\frac{3}{2}} > \frac{1}{2}) \\
& > \left(\frac{1}{4} \log(K^{-2} - \frac{3}{2}) + \log(|b_0|^{-1})\right)(1 + \frac{1}{4} \kappa^{-\frac{3}{2}}) \quad \text{(Since } \log(K^{-2}) < 0) \\
& = \left(\frac{1}{4} \log(K^{-2} - \frac{3}{2}) + \log(|b_0|^{-1})\right)(1 + \frac{1}{4} \kappa^{-\frac{3}{2}}) \quad (79) \\
& > \left(\frac{1}{4} \log(a_\tau \kappa) + \log(|b_0|^{-1})\right)(1 + \frac{1}{4} \kappa^{-\frac{3}{2}}) \quad \text{(Since } K^{-2}\kappa^{-1} > a_k) \\
& = \left(\frac{1}{4} \log(a_\tau \kappa) + \log(|b_0|^{-1})\right)(1 + 4\kappa^{-\frac{3}{2}})/4\kappa^{-\frac{3}{2}} \\
& = \left(\frac{1}{4} \log(a_\tau \kappa) + \log(|b_0|^{-1})\right)log(1 + 4\kappa^{-\frac{3}{2}})^{-1} \quad \text{(Since } \log(1 + x) \geq x/(1 + x) \).
\end{align*}

It follows that
\begin{align*}
t > \left(\frac{1}{4} \log(a_\tau \kappa) + \log(|b_0|^{-1})\right)log(1 + 4\kappa^{-\frac{3}{2}})^{-1} \\
& = \left(\frac{1}{4} \log(\sqrt{a_\tau \kappa}) + \log(|b_0|^{-1})\right)log(1 + 4\kappa^{-\frac{3}{2}})^{-1} \\
& > \left(\frac{1}{4} \log(\sqrt{a_\tau \kappa}) + \log(|b_0|^{-1})\right)log(1 + 4\kappa^{-\frac{3}{2}})^{-1} \quad (80) \\
& = \log(1 + 4\kappa^{-\frac{3}{2}})\frac{1}{4} \sqrt{a_\tau \kappa}/|b_0| \).
\end{align*}

Hence \( (1 + 4\kappa^{-\frac{3}{2}})^t > \frac{1}{4} \sqrt{a_\tau \kappa}/|b_0| \), and therefore \( |b_0| > |b_0|(1 + 4\kappa^{-\frac{3}{2}})^t > \frac{1}{4} \sqrt{a_\tau \kappa} \), which contradicts that \( P(t) \) holds and lead to contradiction.

Therefore there must exists some \( \tau \) such that \( |b_\tau| > \frac{1}{4} \sqrt{a_\tau \kappa} \). Let \( T < \frac{1}{4} \log(|b_0|^{-1}) \kappa^{-\frac{3}{2}} \) be the smallest such \( \tau \), then the induction will proceed to \( k = T - 1 \). Moreover since \( P(T - 1) \) holds, following the previous analysis, the bounds on \( |a_T| \) also holds, so we have \( |a_T| \in (2\kappa^{-\frac{3}{2}} + \kappa^{-2}\kappa^{-1}) \).

Now to complete the proof we only need to show that \( |b_T| < \frac{1}{2} \sqrt{a_T \kappa} \).
From Eq. (77) we have $|b_T| < |b_{T-1}| + 14a_{T-1}|b_{T-1}|\kappa = (1 + 14a_{T-1}\kappa)|b_{T-1}|$. Since $a_{T-1} < \frac{1}{4}K^{-2}\kappa^{-1}$ and $K > 512$, $(1 + 14a_{T-1}\kappa) < (1 + 14K^{-2}) < 1.1$. So

$$|b_T| < 1.1|b_{T-1}| < 1.1\left(\frac{1}{4}\sqrt{a_{T-1}\kappa}\right). \tag{81}$$

On the other side, note that $a_T > a_{T-1} - 7b_T^2 \kappa^{-3}$ by Eq. (77), where $b_T^2 \kappa < \left(\frac{1}{4}\sqrt{a_{T-1}\kappa}\right)^2 = \frac{1}{16}a_{T-1}\kappa$. We have $a_T > a_{T-1} - \frac{7}{16}a_{T-1}\kappa > (1 - \kappa)a_{T-1}$. Since $\kappa < K^{-1} < \frac{1}{512}$, we have $a_T > 0.99a_{T-1}$ and hence

$$\frac{1}{4}\sqrt{a_{T-1}\kappa} < 1.1\left(\frac{1}{4}\sqrt{a_T\kappa}\right). \tag{82}$$

Combining Eq. (81) and Eq. (82) we have $|b_T| < 1.21\left(\frac{1}{4}\sqrt{a_T\kappa}\right) < \frac{1}{2}\sqrt{a_T\kappa}$. This concludes the proof for this lemma.

**B.4.6 |b| Stays in $(\frac{1}{2}\sqrt{a\kappa}, 2\sqrt{a\kappa})$ as a Decreases When a is Not Too Small**

After showing that $b$ will enter $(\frac{1}{2}\sqrt{a\kappa}, 2\sqrt{a\kappa})$, we now show that it will not leave this region unless $a$ is very small. To do so, we first determine a regime in which we can effectively bound the two-step movement of $b$.

**Lemma 10.** For any $\kappa, a, b$ satisfying

$$\kappa < K^{-1}, \quad |a| < \frac{1}{4}K^{-2}\kappa^{-1}, \quad |b| < 2\sqrt{a\kappa},$$

we have $|b'' - b| < \frac{1}{16}\sqrt{a\kappa}$. 

**Proof of Lemma 10.** Fix $\epsilon = 0.1$, it is straightforward to check that $\kappa, a, b$ satisfies condition B.1. Hence from Eq. (60) and Eq. (61) we have that

$$|b'' - b| < 16|b^3| + 8|abs| + Kb^4 + K|ab^2\kappa| + K|a^2bk^2| + Kb^2\kappa^4 + K|bk^3| + K|\epsilon|b^5\kappa^3. \tag{84}$$

To prove the claim it is sufficient to bound all terms on RHS under $\frac{1}{128}\sqrt{a\kappa}$. Note that with $b < 2\sqrt{a\kappa}$ and $a < K^{-2}\kappa^{-1}$, $\sqrt{a\kappa} < \sqrt{K^{-2}} = K^{-1} < \frac{1}{128}$ and hence $b < 2K^{-1}$.

(i) Since $K > 512$, $a\kappa < K^{-2} < \frac{1}{16384}$. Multiplying $128\sqrt{a\kappa}$ on both sides we have $128(a\kappa)^{\frac{1}{2}} < \frac{1}{128}\sqrt{a\kappa}$.

Since $|b| < 2\sqrt{a\kappa}$, $|b|^2 < 8(a\kappa)^{\frac{1}{2}}$, thus $16|b|^2 < 128(a\kappa)^{\frac{1}{2}} < \frac{1}{128}\sqrt{a\kappa}$.

(ii) Since $|b| < 2\sqrt{a\kappa}$, $8|abs| < 16(a\kappa)^{\frac{1}{2}} < \frac{1}{1024}\sqrt{a\kappa}$. The last inequality holds directly from (i).

(iii) Since $|b| < 2\sqrt{a\kappa}$, $Kb^4 < 16K\kappa^{2}\kappa^2 = 16K(a\kappa)^{\frac{1}{2}}\kappa$. Since $\sqrt{a\kappa} < K^{-1}$, $16K(a\kappa)^{\frac{1}{2}}\kappa < 16K^{-2}\kappa^2\kappa < \frac{16}{16384}\sqrt{a\kappa} < \frac{1}{128}\sqrt{a\kappa}$. Therefore $Kb^4 < \frac{1}{128}\sqrt{a\kappa}$. 

(iv) Since $|b| < 2K^{-1}$, $K|ab^2\kappa| < 2|abs|$, which is less than $\frac{1}{16}\kappa$ from (ii).

(v) Since $|ab| < K^{-1}$, $K|ab^2\kappa| < |abs| < \frac{1}{1024}\sqrt{a\kappa}$.

(vi) Note that as $\kappa < 0.1$ in condition B.1, $\kappa^4 < \frac{1}{317}$. Since $|b| < 2\sqrt{a\kappa} < 2K^{-1}$, $b^2 < 4K^{-1}\sqrt{a\kappa}$, and thus $Kb^4 < 4\sqrt{a\kappa}\kappa^4 < \frac{1}{128}\sqrt{a\kappa}$.

(vii) Since $b < 2\sqrt{a\kappa}$, $K|bk^3| < 2K\kappa^5\sqrt{a\kappa}$. Given $\kappa < K^{-1} < \frac{1}{4}K^{-\frac{1}{2}}$, we have $\kappa^5 < \frac{1}{1024}K^{-1}$, and hence $2K\kappa^5\sqrt{a\kappa} < \frac{1}{128}\sqrt{a\kappa}$. Thus $K|bk^3| < \frac{1}{128}\sqrt{a\kappa}$.

(viii) Since we fixed $\epsilon = 0.1$, $\kappa < K^{-1} < \frac{1}{128} < \frac{1}{2}\epsilon^{-\frac{1}{2}}$, $\kappa^3 < \frac{1}{128}\epsilon^{-1}$. Multiplying $4\epsilon\sqrt{a\kappa}$ on both sides we have $4\epsilon\sqrt{a\kappa}\kappa^3 < \frac{1}{128}\sqrt{a\kappa}$. Since $b^2 < 4K^{-1}\sqrt{a\kappa}$ from (vi), we have $K\epsilon b^2\kappa^3 < K(4K^{-1}\sqrt{a\kappa})\kappa^3 = 4\epsilon\kappa\kappa^3 < \frac{1}{128}\sqrt{a\kappa}$.

Now that we have bounded every monomial term on RHS of Eq. (84) by $\frac{1}{128}\sqrt{a\kappa}$, we have $|b'' - b| < \frac{1}{16}\sqrt{a\kappa}$, which completes the proof. \qed
Here we restate the condition for Lemma 10

**Condition B.5** (Condition for small \(b\) movement).

\[
\kappa < K^{-1}, \\
|a| < K^{-2}K^{-1}, \\
|b| < 2\sqrt{d}\kappa.
\]  

(85)

With the two-step movement of \(c\) bounded above, we may proceed to state the lemma that guarantees \(c\) will not leave \((\frac{1}{4}\sqrt{d}\kappa, 2\sqrt{d}\kappa)\) unless \(d\) is very small.

**Lemma 11.** For any \(\kappa\) and initialization \(a_0, b_0\) satisfying \(\kappa < \frac{1}{16}K^{-1}\),

\[
|a_0| \in (\kappa^2, \frac{1}{2}K^{-2}K^{-1}), \\
|b_0| \in (\frac{1}{4}\sqrt{\kappa a_0}, 2\sqrt{\kappa a_0}).
\]

There exists some \(T \leq 16a_0\kappa^{-\frac{12}{13}}\) such that \(a_T < \kappa^2\) and for all \(t < T\), \(a_t > \kappa^2\) and \(b_t \in (\frac{1}{4}\sqrt{a_t}\kappa, 2\sqrt{a_t}\kappa)\).

**Proof of Lemma 11.** First we check that the region defined is not empty. This is true since given \(\kappa < \frac{1}{16}K^{-1}\), we have \(\frac{1}{2}K^{-2}K^{-1} > 4K^{-1} > K^{-2} > \kappa^2\).

To prove the claim we consider the inductive hypothesis

\[
P(k): a_k \in (\kappa^2, a_0 - \frac{1}{16}(k-1)\kappa^2]\]

and \(|b_k| \in (\frac{1}{4}\sqrt{a_k}\kappa, 2\sqrt{a_k}\kappa)\).

Assume that \(P(k)\) holds for some \(k\). Since \(a_k < a_0 < \frac{1}{4}K^{-2}K^{-1}\), we have \(|b_k| < 2\sqrt{a_k}\kappa < 2\sqrt{\frac{1}{2}K^{-2}K^{-1}}\kappa = K^{-1}\). With \(\kappa < \frac{1}{16}K^{-1}\) and \(a_k < a_0 < \frac{1}{4}K^{-2}K^{-1}\), we have \(\kappa, b_k, a_k\) satisfying condition B.2 and condition B.5. Thus \(a_{k+1} < a_k - b_k^2\kappa^3\), \(a_{k+1} > a_k - 8b_k^2\kappa^3\) (by Lemma 5), and \(|b_{k+1} - b_k| < \frac{1}{16}\sqrt{a_k}\kappa\) (by Lemma 10).

Observe that since \(a_{k+1} > a_k - 8b_k^2\kappa^3\),

\[
2\sqrt{a_{k+1}} - 2\kappa > 2\sqrt{(a_k - 8b_k^2\kappa^3)\kappa} = 2\sqrt{(a_k\kappa)(1 - 32\kappa^4)} = 2\sqrt{1 - 32\kappa^4}\sqrt{a_k}\kappa.
\]

Note that with \(\kappa < \frac{1}{16}K^{-1}\) where we assume \(K > 128\), we have \(\sqrt{1 - 32\kappa^4} > 0.99\) and hence \(\sqrt{a_{k+1}} > 0.99\sqrt{a_k}\kappa\). Now we will show that \(b_{k+1}\) will not leave \((\frac{1}{4}\sqrt{a_{k+1}}\kappa, 2\sqrt{a_{k+1}}\kappa)\). There are three cases to consider:

1. When \(|b_k| \in (\sqrt{a_k}\kappa, 2\sqrt{a_k}\kappa)\), along with \(|b_k| < K^{-1}\) we have condition B.3 satisfied and thus \(|b_{k+1}| < |b_k|(1-b_k^2)\) by Lemma 6. Since \(\kappa < \frac{1}{16}K^{-1} < \frac{1}{512}\), we have \(\kappa^2 < \frac{1}{4}K^{-2}\), and thus \(\kappa^2 > 4\sqrt{2}\kappa^2\).

Moreover, since \(a_k > \kappa^2\), we have \(|b_k| > \sqrt{a_k}\kappa > \kappa^2 > 4\sqrt{2}\kappa^2\). Squaring both sides we have \(b_k^2 > 32\kappa^4\). Hence \(1 - 32\kappa^4 > 1 - b_k^2 > 1 - 2b_k^2 + b_k^4 = (1 - b_k^2)^2\). The last inequality holds since \(b_k^2 > b_k^4\) as \(b_k^2 < 1\). Now taking the square root on both sides we have \(1 - b_k^2 < \sqrt{1 - 32\kappa^4}\). Since \(|b_k| < \sqrt{a_k}\kappa\), combining with Eq. (87) and \(1 - b_k^2 < \sqrt{1 - 32\kappa^4}\kappa\) we have \(|b_{k+1}| < 2\sqrt{a_k}\kappa(1 - b_k^2) < 2\sqrt{1 - 32\kappa^4}\sqrt{a_k}\kappa < 2\sqrt{a_{k+1}}\kappa\), which gives the desired upper bound to \(|b_{k+1}|\).

Now we prove the lower bound for \(|b_{k+1}|\). Since we know \(|b_{k+1} - b_k| < \frac{1}{10}\sqrt{a_k}\kappa\), by triangle inequality, \(|b_k| > \sqrt{a_k}\kappa\) implies \(|b_{k+1} > \frac{15}{10}\sqrt{a_k}\kappa > \frac{1}{4}\sqrt{a_k}\kappa > \frac{1}{4}\sqrt{a_{k+1}}\kappa\).

2. When \(|b_k| \in [\frac{1}{2}\sqrt{a_k}\kappa, \sqrt{a_k}\kappa]\), since \(|b_{k+1} - b_k| < \frac{1}{16}\sqrt{a_k}\kappa\), by triangle inequality we have \(|b_{k+1}| \in [\frac{1}{2}\sqrt{a_k}\kappa - \frac{1}{16}\sqrt{a_k}\kappa, \frac{17}{16}\sqrt{a_k}\kappa]\). Since \(\frac{1}{2}\sqrt{a_k}\kappa > \frac{1}{4}\sqrt{a_k}\kappa > \frac{1}{4}\sqrt{a_{k+1}}\kappa\) and \(\frac{17}{16}\sqrt{a_k}\kappa < 2\sqrt{a_{k+1}}\kappa\) as \(\sqrt{a_{k+1}}\kappa > 0.99\sqrt{a_k}\kappa\), we have \(|b_{k+1}| \in [\frac{1}{4}\sqrt{a_k}\kappa, 2\sqrt{a_k}\kappa]\).

3. When \(|b_k| \in (\frac{1}{4}\sqrt{a_k}\kappa, \frac{1}{2}\sqrt{a_k}\kappa]\), along with \(|b_k| < K^{-1}\) we have condition B.4 satisfied, and thus \(|b_{k+1}| > |b_k| + |b_k|a_k\kappa > |b_k|\). Since \(\sqrt{a_{k+1}}\kappa < \sqrt{a_k}\kappa, |b_{k+1}| > \frac{1}{4}\sqrt{a_{k+1}}\kappa\).

On the other side, since \(|b_{k+1} - b_k| < \frac{1}{16}\sqrt{a_k}\kappa\) and \(|b_k| < \frac{1}{2}\sqrt{a_k}\kappa\), by triangle inequality we have \(|b_{k+1}| < (\frac{1}{16} + \frac{1}{2}\sqrt{a_k}\kappa < 2\sqrt{a_k}\kappa\). The last step holds since \(\sqrt{a_{k+1}}\kappa > 0.99\sqrt{a_k}\kappa\).
Summarizing the three cases, we know that \( b_{k+1} \in (\frac{1}{2} \sqrt{a_{k+1} \kappa}, 2 \sqrt{a_{k+1} \kappa}) \).

By the assumption of \( P(k) \) we also have \( a_k > \frac{\kappa^2}{2} \) and \( a_k < a_0 - \frac{1}{16}(k-1)\kappa^2 \). Since we know \( b_k > \frac{1}{4} \sqrt{a_k \kappa} \), we have \( b_k^2 |\kappa^3| > \frac{1}{16} a_k \kappa^4 > \frac{1}{16} \frac{\kappa^6}{2} \). Thus \( a_{k+1} < a_k - b_k^2 |\kappa^3| < a_k - \frac{1}{16} \frac{\kappa^6}{2} < a_0 - \frac{1}{16} k \kappa^2 \). Therefore unless \( b_{k+1} < \kappa^2 \), \( P(k+1) \) holds. Note that there must be some \( t \) such that \( a_t < \kappa^2 \) since when \( t > 16 a_t \kappa \frac{13}{12} + 1 \), \( a_0 - \frac{1}{16} (t-1) \frac{\kappa^6}{2} < 0 \). We induct on \( k \) from 1, the base case holds by the initialization of \( b_0 \) and \( a_0 \). Let \( T \) be the smallest \( t \) such that \( a_t < \kappa^2 \), at which we terminate the induction. Then for all \( t < T \), \( a_t \in (\kappa^2, a_0] \) and \( b_t \in (\frac{1}{2} \sqrt{a_t \kappa}, 2 \sqrt{a_t \kappa}) \). This concludes the proof.

**Corollary B.3.** Following the initialization condition and notation of Lemma 11, if \( a_0 > 2 \kappa^2 \), there exists some \( \tau < T \) such that \( a_t \in (\frac{1}{2} \kappa^2, 2 \kappa^2) \).

**Proof of Corollary B.3.** We will follow the notations defined in the proof of Lemma 11. By definition of \( T \), \( P(t) \) holds for all \( t < T \). Then for all \( t < T \), we have \( a_t > \kappa^2, b_t < K^{-1} \), and \( a_{t+1} < a_t - b_t^2 \kappa^3 \). Hence \( |a_{t+1} - a_t| < K^{-2} \kappa^3 < \frac{1}{2} \kappa^2 \) since we assumed \( K > 128 \).

Since \( a_0 > 2 \kappa^2 \) and \( a_T < \kappa^2 < \frac{1}{2} \kappa^2 \), combining with \( |a_{t+1} - a_t| < \frac{1}{2} \kappa^2 \) we know that there must exist some \( \tau \) such that \( a_\tau \in (\frac{1}{2} \kappa^2, 2 \kappa^2) \).

**Corollary B.4.** Following Lemma 11, if \( a_0 \in (\frac{1}{2} \kappa^2, 2 \kappa^2) \), \( T > \frac{1}{128} \kappa^{-4} \).

**Proof of Corollary B.4.** We will follow the notations defined in the proof of Lemma 11. By definition of \( T \), \( P(t) \) holds for all \( t < T \). Then for all \( t < T \), we have \( a_t < a_0 = 2 \kappa^2 \) and \( b_t < 2 \sqrt{a_t \kappa} < 2 \sqrt{2} \kappa^2 \). It follows that \( a_{t+1} > a_t - 8 b_t^2 \kappa^3 > a_t - 64 \kappa \frac{3}{2} \). Since \( a_0 - a_T > \frac{3}{2} \kappa^2 - \kappa^2 = \frac{1}{2} \kappa^2 \), we must have \( T > \frac{1}{2} \kappa^2 / 64 \kappa \frac{3}{2} = \frac{1}{128} \kappa^{-4} \).

### B.5 Phase II: Convergence Along the Parabola

In Appendix B.4 we have shown that for a certain range of initializations, \((a, b)\) converges close to the parabola \( 2b^2 = a \kappa \) very fast. In this section, we will show that \((a, b)\) will slowly move along the parabola, and will eventually converge to a point with sharpness just below the EoS threshold \( 2/\eta = 2/\kappa^2 \).

To facilitate the analysis, we define the residual \( \xi = b^2 - \frac{1}{2} a \kappa - \frac{1}{16} \kappa^4 \) and consider a small perturbation constant threshold \( \delta = 0.04 \).

Follow from Corollary B.1 we have that for any \( \epsilon < 0.5 \), for any \( \kappa, a, b \) satisfying condition B.1,

\[
\xi'' = b'' - \frac{1}{2} a'' \kappa - \frac{1}{16} \kappa^4
= (b^2 + 8 a b \kappa - 16 b^4) \n + O(b) (O(b^3) + O(ab^2 \kappa) + O(ab^2 \kappa^2) + O(b^2 \kappa^4) + O(b^4 \kappa^5) + O(ab^2 \kappa^3) + O(ab^2 \kappa^4) + O(b^4 \kappa^4) + O(b^4 \kappa^5))
- \frac{1}{2} a \kappa + 2 b \kappa^4 + \kappa (O(ab^2 \kappa^3) + O(b^3 \kappa^5) + O(b^3 \kappa^4) + O(b^4 \kappa^4)) - \frac{1}{16} \kappa^4
= b^2 - 32 b^4 + 16 b^2 a \kappa - \frac{1}{2} a \kappa + 2 b^2 \kappa^4 - \frac{1}{16} \kappa^4
+ O(b^5) + O(ab^3 \kappa) + O(a^2 b^2 \kappa^2) + O(b^3 \kappa^4) + O(b^3 \kappa^5) + O(ab^2 \kappa^3) + O(ab^2 \kappa^4) + O(b^2 \kappa^4) + O(b^2 \kappa^5)
= (1 - 32 b^2) \left( b^2 - \frac{1}{2} a \kappa - \frac{1}{16} \kappa^4 \right) +
+ O(b^5) + O(ab^3 \kappa) + O(a^2 b^2 \kappa^2) + O(b^3 \kappa^4) + O(b^2 \kappa^5) + O(ab^2 \kappa^3) + O(ab^2 \kappa^4) + O(b^2 \kappa^4)
= (1 - 32 b^2) \xi + O(b^5) + O(ab^3 \kappa) + O(a^2 b^2 \kappa^2) + O(b^3 \kappa^4) + O(b^2 \kappa^5) + O(ab^2 \kappa^3) + O(ab^2 \kappa^4) + O(b^2 \kappa^4).
\]

When \( b < \kappa \), the above expression can be further reduced to

\[
\xi'' = (1 - 32 b^2) \xi + O(b^5) + O(ab^3 \kappa) + O(a^2 b^2 \kappa^2) + O(b^3 \kappa^4) + O(b^2 \kappa^5) + O(ab^2 \kappa^3) + O(ab^2 \kappa^4) + O(b^2 \kappa^4). \tag{89}
\]
Hence there exists absolute constants $K$ such that for all $\epsilon < 0.5$, for all $a, b, \kappa$ satisfying condition B.1 and $|b| < \kappa$, we have $\xi'' = (1 - 32\delta^2)\xi + R_\xi$ where

$$
|R_\xi| < K |b^5| + K |ab^3\kappa| + K |a^2b^2\kappa^2| + K |b^3\kappa^4| + K |eb^2\kappa^4|
$$

(90)

Now fix $\delta = 0.04$, we will determine the regime such that $|R_\xi|$ is less than $\delta b^2\kappa^4$.

**Lemma 12.** For any $\kappa, a, b$ satisfying

$$
\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1}, \quad |b| < 2\sqrt{2}\kappa^\frac{3}{2}, \quad |a| < 2\kappa^\frac{3}{2}
$$

(91)

where $\delta = 0.04$, we have

$$
|\xi'' - (1 - 32\epsilon^2)\xi| < \delta b^2\kappa^4.
$$

(92)

**Proof of Lemma 12.** Fix $\epsilon = \frac{1}{5}\delta K^{-1}$, claim that $\kappa, b, a$ in the given regime satisfies condition B.1. We check the conditions one by one:

(i) Since we assume $K > 128$, fixing $\epsilon = \frac{1}{5}\delta K^{-1}$ satisfies $\epsilon < 0.5$

(ii) With both $\delta$ and $K^{-1}$ less than 0, $\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1} < 0.1$. Also $\frac{1}{80\sqrt{2}}\delta K^{-1} < \frac{1}{\delta}K^{-1} = \epsilon^2 < \epsilon^4$. Thus $\kappa < \min\{0.1, \epsilon^4\}$.

(iii) With $\epsilon = \frac{1}{5}\delta K^{-1}$ and $\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1}$, $\epsilon K^{-1} > 16\sqrt{2} > 2\kappa^\frac{3}{2} > |a|$. Thus $|a| < \kappa^\frac{3}{2}$.

(iv) Since $c\epsilon^{-1} > 16\sqrt{2}$ and $\kappa < 1, \epsilon^2 - 5 > \frac{\sqrt{5}}{5} > 1 > 2\sqrt{2}\kappa^\frac{3}{2}$. Thus $|b| < \min\{1, \epsilon K^{-2}/5\}$.

Thus Eq. (90) applies, and we only need to bound every term on its RHS by $\frac{1}{\delta}b^2\kappa^4$ to complete the proof. We will do that term by term.

(i) Since $\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1} < 1$, we have $\kappa^\frac{3}{2} < \frac{1}{80\sqrt{2}}\delta K^{-1}$. Multiplying $16\sqrt{2}\kappa^3$ on both sides we have $16\sqrt{2}\kappa^\frac{3}{2} < \frac{1}{\delta}K^{-1}\kappa^4$. Note that since $|b| < 2\sqrt{2}\kappa^\frac{3}{2}$, $|b^3| < 16\sqrt{2}\kappa^\frac{3}{2}$, so $|b^3| < \frac{1}{\delta}K^{-1}\kappa^4$. Multiplying $Kb^2\kappa$ on both sides gives $K|ab^3\kappa| < \frac{1}{\delta}b^2\kappa^4$.

(ii) Since $\kappa^\frac{3}{2} < \frac{1}{80\sqrt{2}}\delta K^{-1} < \frac{1}{20\sqrt{2}}\delta K^{-1}$, multiplying $4\sqrt{2}\kappa^3$ on both sides we have $4\sqrt{2}\kappa^\frac{3}{2} < \frac{1}{\delta}K^{-1}\kappa^3$. Note that since $|b| < 2\sqrt{2}\kappa^\frac{3}{2}$ and $|a| < 2\kappa^\frac{3}{2}$, $|ab| < 4\sqrt{2}\kappa^\frac{3}{2}$, we have $|ab| < \frac{1}{\delta}K^{-1}\kappa^3$. Multiplying $Kab\kappa^2$ on both sides gives $K|ab^2\kappa^3| < \frac{1}{\delta}b^2\kappa^4$.

(iii) Since $\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1} < 1$, we have $\kappa^3 < \kappa < \frac{1}{\delta}K^{-1}\kappa^2$. Multiplying $4\kappa^5$ on both sides gives $4\kappa^5 < \frac{1}{\delta}K^{-1}\kappa^2$. Since $|a| < 2\kappa^\frac{3}{2}$, we have $a^2 < 4\kappa^5 < \frac{1}{\delta}K^{-1}\kappa^2$. Multiplying $Kab\kappa^2$ on both sides, we have $K\kappa^3b^2\kappa^2 < \frac{1}{\delta}b^2\kappa^4$.

(iv) Since $\kappa < \frac{1}{2}, 2\kappa^\frac{3}{2} < \kappa$. Thus $|b| < 2\kappa^\frac{3}{2} < \kappa < \frac{1}{80\sqrt{2}}\delta K^{-1} < \frac{1}{\delta}K^{-1}$. Multiplying $Kb^2\kappa^4$ on both sides gives $K|b^3\kappa^4| < \frac{1}{\delta}b^2\kappa^4$.

(v) Since we fixed $\epsilon = \frac{1}{5}\delta K^{-1}$, $K\epsilon b^2\kappa^4 = \frac{1}{\delta}b^2\kappa^4$.

Therefore we have

$$
|R_\xi| < K |b^5| + K |ab^3\kappa| + K |a^2b^2\kappa^2| + K |b^3\kappa^4| + K |eb^2\kappa^4| < \delta b^2\kappa^4.
$$

(93)

Plugging back to $\xi'' = (1 - 32\delta^2)\xi + R_\xi$ completes the proof. \(\square\)

Here we restate the condition for Lemma 13:

**Condition B.6.** With $\delta = 0.04$ and $K > 512$,

$$
\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1}, \quad |b| < 2\sqrt{2}\kappa^\frac{3}{2}, \quad |a| < 2\kappa^\frac{3}{2}.
$$

(94)

**Corollary B.5.** For any $\kappa, a, b$ satisfying condition B.6, if $|\xi| > \frac{1}{10^6}\delta\kappa^4$, we have $|\xi''| < (1 - 4\kappa^\frac{3}{2})|\xi|$.
Proof of Corollary B.5. Since condition B.6 holds, by Lemma 13 we have
\[|\xi''| < |(1 - 32b^2)\xi| + \delta b^2 \kappa^4.\] (95)
Thus if \(|\xi| > \frac{1}{16}\delta \kappa^4\), it follows that
\begin{align*}
|\xi''| &< |(1 - 32b^2)\xi| + \delta b^2 \kappa^4 \\
&= (1 - 32b^2)|\xi| + \delta b^2 \kappa^4 \quad (\text{Since } 32b^2 < 1) \\
&= |\xi| - 16b^2|\xi| - (16b^2|\xi| - \delta b^2 \kappa^4) \\
&< |\xi| - 16b^2|\xi| - b^2(16(\frac{1}{16}\delta \kappa^4) - \delta \kappa^4) \quad (\text{Since } |\xi| > \frac{1}{16}\delta \kappa^4) \\
&= |\xi| - 16b^2|\xi| \\
&< |\xi| - 4\kappa^2|\xi| \quad (\text{Since } |b| > \frac{1}{2}\kappa^2) \\
&= (1 - 4\kappa^2)|\xi| \cdot
\end{align*}

\[\square\]

B.5.1 Phase II Stage 1

In this stage we will show that after \(|b|\) gets close to \(\sqrt{a_1/2}\) while \(a\) decreases to around \(2\kappa^2\) from Phase I of the convergence, the residual of \((b, a)\) to the parabola will further decrease to below \(\frac{3}{8}\delta\kappa^4\).

Lemma 13. For any \(\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1}\), for all initialization \((b_0, a_0)\) such that \(a_0 \in \left(\frac{3}{2}\kappa^2, 2\kappa^2\right)\) and \(|b_0| \in \left(\frac{1}{2}\sqrt{\alpha_0}K, 2\sqrt{\alpha_0}K\right)\). Let \(T\) be the time that \(a\) exits \((\kappa^2, 2\kappa^2)\) as characterized in Lemma 11 and Corollary B.4. There exists some \(\tau < T\) such that \(\xi \leq \frac{1}{8}\delta\kappa^4\).

Proof of Lemma 13. First note that since \(\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1} < \frac{1}{16}K^{-1}\), the initialization condition given is a subset of the valid initialization for Lemma 11. Thus for all \(t < T\), we have \(a_t \in (\kappa^2, 2\kappa^2)\) and \(|b_t| \in \left(\frac{1}{2}\sqrt{\alpha_t}K, 2\sqrt{\alpha_t}K\right)\).

Hence \(|b_t| < 2\sqrt{2\kappa^2}K = 2\sqrt{2}\kappa^2\) and \(|b_t| > \sqrt{\frac{1}{4}\kappa^2 K} = \frac{1}{2}\kappa^2\). Therefore \((b_t, a_t)\) satisfies condition B.6 and \(\xi_{t+1} - (1 - 32b^2)\xi_t < \delta b^2 \kappa^4\). Also note that with \(K > 512\) and \(\delta = 0.05\), \(b_t^2 < 8\kappa^2\). Thus for all \(\tau < T\) such that for all \(t < \tau, |\xi| > \frac{1}{16}\delta \kappa^4\), we have \(|\xi_T| < (1 - 4\kappa^2)\xi_T\). Now we only need to show that \(|\xi|\) will decrease sufficiently fast.

Consider \(\tau = \left[\log(1 - 4\kappa^2) \left(\frac{1}{2} \delta \kappa^4 \right) \right] / 10\kappa^2\) \(\geq \log(\frac{1}{2} \delta \kappa^4) = \log(80\delta^{-1}\kappa^{-\frac{1}{2}}) = \frac{\log(80\delta^{-1}\kappa^{-\frac{1}{2}})}{\log(1 - 4\kappa^2)} \leq \frac{\log(1 - 4\kappa^2)}{\log(1 - 4\kappa^2)}.\)

Since \(\log(1 - 4\kappa^2) < -4\kappa^2\) by a second order Taylor expansion, we have \(\tau < \log(80\delta^{-1}\kappa^{-\frac{1}{2}})/4\kappa^2\). Substituting \(\delta = 0.04\) in the expression, \(\log(80\delta^{-1}\kappa^{-\frac{1}{2}}) = \log(20000) + \log(\kappa^{-\frac{1}{2}}) = 8 + \log(\kappa^{-\frac{1}{2}}).\) Observe that for all \(x > 175\), we have \(8 + \log(x) < \sqrt{x}\).

Since \(\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1} < \frac{1}{512 \times 2000\sqrt{2}} < \frac{1}{175}\), let \(x = \kappa^{-\frac{1}{2}}\), we have \(8 + \log(\kappa^{-\frac{1}{2}}) < \kappa^{-\frac{1}{2}}.\) Hence \(\log(80\delta^{-1}\kappa^{-\frac{1}{2}}) < \kappa^{-\frac{1}{2}}\) and \(\tau < \kappa^{-\frac{1}{2}}/4\kappa^2 = \frac{1}{2}\kappa^{-\frac{12}{2}}.\) Recall from Corollary B.4 we have \(T > \frac{3}{17}\kappa^{-4}\). If we assume \(K > 512\), then \(\kappa < \frac{1}{512 \times 2000\sqrt{2}} < \frac{1}{175}\), and thus \(\kappa^{-\frac{1}{2}} > 32\) and \(T > \frac{3}{17}\kappa^{-4} > \frac{1}{8}\kappa^{-\frac{12}{2}} > \tau\).

Since \(\tau < T, a_T > \kappa^2\). For all \(t < \tau, |\xi| > \frac{1}{16}\delta \kappa^4\), then following the analysis above, by definition of \(T\) we have \(|\xi| \leq \frac{1}{8}\delta \kappa^4\). If there exists some \(t < \tau\) such that \(|\xi| \leq \frac{1}{16}\delta \kappa^4\), then setting \(\tau = t\) directly completes the proof. \(\square\)

B.5.2 Phase II Stage 2

In this phase, we show that once \(|\xi|\) is smaller than \(\frac{1}{8}\delta \kappa^4\), \(a\) will decrease slowly while \(|\xi|\) does not increase beyond \(\frac{1}{8}\delta \kappa^4\).

Lemma 14. For all \(\kappa < \frac{1}{80\sqrt{2}}\delta K^{-1}\), for all initialization \((a_0, b_0)\) satisfying \(a_0 \in (\kappa^2, 2\kappa^2)\) and \(|\xi| < \frac{1}{8}\delta \kappa^4\), there exists some \(T < 48\delta^{-1}\kappa^{-\frac{1}{2}} + 1\) such that \(a_T < -\frac{1}{3}(1 - 3\delta)\kappa^3\) and for all \(t < T, a_t > -\frac{1}{3}(1 - 3\delta)\kappa^3\) and \(|\xi_k| < \frac{1}{8}\delta \kappa^4\).
We will consider the claim using induction. Consider the inductive hypothesis

\[ P(k): |\xi_k| < \frac{1}{8} \delta k^4 \text{ and } a_k \in \left( -\frac{1}{8} (1 - 3 \delta) k^3, a_{k-1} - \frac{1}{16} \delta k^7 k \right). \]

Note that \( P(0) \) holds directly from construction, so we proceed to the inductive step. Assuming \( P(k) \) holds, we will show that either \( a_k < -\frac{1}{8} (1 - 3 \delta) k^3 \) or \( P(k + 1) \) holds.

First we verify that \( b_k, a_k \) satisfies condition B.6. Since \( \delta = 0.05 \), \( \left| -\frac{1}{8} (1 - 3 \delta) k^3 \right| \leq \frac{1}{16} \delta k^7 k \). Also since \( a_1 < 2 \kappa \frac{\hat{\xi}}{a} > 2 \kappa \frac{\hat{\xi}}{a} > 2 \kappa \frac{\hat{\xi}}{a} = 2 \kappa \frac{\hat{\xi}}{a} \), we have \( a_k = \frac{1}{10} \delta k^7 k \). Next we establish the lower bounds for \( |b_k| \), which will give lower bound for the movement of \( a \). Since \( a_k > -\frac{1}{8} (1 - 3 \delta) k^3 \) and \( |\xi_k| = |b_k| - \left( \frac{1}{8} a_k k + \frac{1}{16} \delta k^4 \right) < \frac{1}{8} \delta k^4 \), we have

\[ \xi_k^2 > \frac{1}{8} \delta k^4 + \frac{1}{16} \delta k^4 > \frac{1}{8} (-\frac{1}{8} (1 - 3 \delta) k^3) + \frac{1}{16} \delta k^4 - \frac{1}{16} \delta k^4 = \frac{1}{16} \delta k^4. \]

Since \( |b_k| < K^{-1} \) and \( |a_k| < K^{-1} \), condition B.2 is satisfied and we have \( a_{k+1} < a_k - b_k k^3 \leq a_k - \frac{1}{16} \delta k^4 k^3 \). Given that \( a_k = a_{k-1} = -\frac{1}{16} \delta k^4 k^3 \), we have

\[ |\xi_{k+1} - \xi_k| < \delta b_k^2 k^4 + 32 b_k^2 \delta k^4 = \frac{32}{16} \delta k^4. \]

Thus \( P(k + 1) \) implies \( P(k + 2) \) for all \( k \geq 0 \).

In summary we have \( P(k) \) implies \( P(k + 1) \) unless \( a_{k+1} < -\frac{1}{8} (1 - 3 \delta) k^3 \). Note that there must exists some \( t \) such that \( a_{t+1} < -\frac{1}{8} (1 - 3 \delta) k^3 \) for any \( t \geq 485^{-1} \kappa^{-2} + 1 \), if the induction proceed to \( P(\tau) \), then \( a_{\tau} - \frac{1}{16} \delta k^4 (\tau - 1) < a_{\tau} - 3 \kappa \frac{\hat{\xi}}{a} < -\kappa \frac{\hat{\xi}}{a} < -\frac{1}{8} (1 - 3 \delta) k^3 \), which violates \( P(\tau) \). Let \( T < 485^{-1} \kappa^{-2} + 1 \) be the first such that \( a_{t} < -\frac{1}{8} (1 - 3 \delta) k^3 \), then by construction we have for all \( t < T \), \( P(t) \) holds. This completes the proof of the lemma.

**Corollary B.6.** Following Lemma 14, \( a_{T-1} \in \left( -\frac{1}{8} (1 - 3 \delta) k^3, a_{T-2} < \frac{1}{16} (1 + 2 \delta) k^3 \right) \).

**Proof of Corollary B.6.** Denote \( T - 1 \) by \( \tau \), by definition of \( T \), we know \( P(\tau) \) holds and therefore we have \( b_{\tau}^2 < 2 \kappa \frac{\hat{\xi}}{a} \), \( a_{\tau} > -\frac{1}{8} (1 - 3 \delta) k^3 \) and \( a_{\tau} > a_{\tau} - 5 b_k^2 k^3 \). Combining above we have \( a_{\tau} > a_{\tau} - 10 \kappa \frac{\hat{\xi}}{a} k^3 \), so \( a_{\tau} < a_{\tau} + 10 \kappa \frac{\hat{\xi}}{a} < -\frac{1}{8} (1 - 3 \delta) k^3 + 10 \kappa \frac{\hat{\xi}}{a} \). Note that since we set \( \delta = 0.04 \), we have

\[\left| a_{\tau} - \frac{1}{16} (1 + 2 \delta) k^3 \right| = \left| a_{\tau} + \frac{1}{16} (1 + 2 \delta) k^3 \right| = \left| a_{\tau} - \frac{3}{8} \frac{\hat{\xi}}{a} k^3 \right| < \frac{1}{16} (1 - 3 \delta) k^3.\]

Since \( \kappa^{-2} > K^{-2} > 5000 \), we have \( 10 \kappa \frac{\hat{\xi}}{a} < \frac{1}{16} k^3 = -\frac{1}{16} (1 + 2 \delta) k^3 - \left( -\frac{1}{8} (1 - 3 \delta) k^3 \right). \) Adding \( -\frac{1}{8} (1 - 3 \delta) k^3 \) on both sides, we have \( a_{\tau} < -\frac{1}{8} (1 - 3 \delta) k^3 + 10 \kappa \frac{\hat{\xi}}{a} < a_{\tau} - \frac{1}{16} (1 + 2 \delta) k^3. \) Combining with \( a_{\tau} > -\frac{1}{8} (1 - 3 \delta) k^3 \) concludes the proof.

**B.5.3 Phase II Stage 3**

Here we state the lemma which proves the final convergence of the two step trajectory. The proof is very similar to that of Lemma 7 except \( a \) is negative now and \( |b| \) is decreasing.

**Lemma 15** (Final Convergence). For all \( \kappa \leq \frac{1}{16} K^{-1} \), for all \( a_0, b_0 \) satisfying \( a_0 \in \left( -\frac{1}{8} (1 - 3 \delta) k^3, a_0 - \frac{1}{16} (1 + 2 \delta) k^3 \right) \) and \( |\xi_0| = b_0^2 - \frac{1}{8} a_0 k + \frac{1}{16} \delta k^4 \leq \frac{1}{8} \delta k^4 \) for all \( \epsilon > 0 \), there exists some \( T < 25 \log(e^{-1}) \) such that for all \( t \geq T \), \( |b_t| < \epsilon \) and \( a_t \in \left( -\frac{1}{8} \kappa^3, a_0 - \frac{1}{16} (1 + 2 \delta) k^3 \right) \).

**Proof.** We will prove the claim using induction. Consider the inductive hypothesis

\[ P(k): |b_k| \leq |b_0| (1 - \frac{1}{16} (1 + 2 \delta) k^3), a_0 - a_{k-1} \in [0, 8 \sqrt{2} \kappa (|b_0| - |b_k|)). \]

When \( k = 0 \), the statement holds trivially, so we proceed to the inductive step. Assume \( P(k) \) holds for some \( k \in \mathbb{N} \), we want to show that \( P(k + 1) \) holds as well.
First we check that \((a_k, b_k)\) with \(\kappa < \frac{1}{10}K^{-1}\) satisfies condition B.4.

Since \((1 - \frac{1}{10}(1 + 2\delta)) < 1\), by the inductive hypothesis and the initialization condition on \(|b_0|\) we have \(|b_k| < |b_0|\). It is also from the inductive hypothesis that \(|a_k| > |a_0|\), thus to show \(|b_k| < \frac{1}{2\sqrt{2}}|a_k|\kappa\), one only needs to show for \(k = 0\) case, which is equivalent to \(b_0^2 < -\frac{1}{8}a_0\kappa\).

From the initialization condition, \(\epsilon_0 = |b_0| < \frac{1}{8}a_0\kappa - \frac{1}{16}\kappa^3\). Since \(a_0 < -\frac{1}{10}(1 + 2\delta)\kappa^3\), we must have \(\frac{1}{2}a_0 + \frac{1}{16}\kappa^4 < 0 \leq b_0^2\). It follows that
\[
\begin{align*}
b_0^2 &< \frac{1}{8}a_0\kappa + \frac{1}{16}\kappa^4 + \frac{1}{8}\kappa^4 \\
&= \frac{5}{8}a_0\kappa + \frac{1}{16}(1 + 2\delta) - \frac{1}{8}a_0\kappa \\
&< \frac{5}{8}(1 + 2\delta)\kappa^3 + \frac{1}{16}(1 + 2\delta)\kappa^4 - \frac{1}{8}a_0\kappa \\
&= \frac{1}{8}(1 + 2\delta)\kappa^4 - \frac{1}{8}a_0\kappa \\
&= \frac{1}{8}|a_0|\kappa.
\end{align*}
\]

From the initialization condition we have \(a_0 < -\frac{1}{10}(1 + 2\delta)\kappa^3 = -0.108\kappa^3 < -\frac{1}{10}\kappa^3\), so \(|a_k| > |a_0| > \frac{1}{10}\kappa^3\). For upper-bound on \(|a_k|\) we note that \(a_0 > -\frac{3}{4}(1 - 3\delta)\kappa^3 > -\kappa^3\) by initialization, combining with the inductive hypothesis we have \(a_k > -\kappa^3 - 2\kappa(|b_0| - |b_1|) > -\kappa^3 - 2|b_0|\). Since \(b_0^2 < \frac{1}{8}|a_0|\kappa < \frac{3}{4}(1 - 3\delta)\kappa^4 < \frac{3}{2}\kappa^2\), \(|b_0| < \frac{3}{2}\kappa^2\), so \(a_k > -\kappa^3 - \frac{3}{2}\kappa^2\) and hence \(|a_k| > \frac{3}{2}\kappa^2 < K^{-2}K^{-1}\) since we assumed \(\kappa < \frac{1}{10}K^{-1}\). Therefore we have shown that \(\kappa, a_k, b_k\) satisfies condition B.4 and by Lemma 7 we have \(|b_k + 1| < |b_k + a_kb_k|\).

Since \(1 + a_k\kappa > 0\) as \(|a_k| < \frac{1}{8}\kappa^3\) and \(\kappa < K^{-1} < \frac{1}{16}\kappa\), we may write the update of \(b_k\) as \(|b_{k+1}| < |b_{k+1}(1 + a_k\kappa)|\).

Since \(a_k < a_0 < -\frac{1}{10}(1 + 2\delta)\kappa^4\), we have \(|b_{k+1}| < |b_0|(1 - \frac{1}{10}(1 + 2\delta)\kappa^4)\). Combining with the inductive hypothesis that \(|b_{k}| < |b_0|(1 - \frac{1}{10}(1 + 2\delta)\kappa^4)^k\), we have \(|b_{k+1}| < |b_0|(1 - \frac{1}{10}(1 + 2\delta)\kappa^4)^{k+1}\).

Since condition B.4 is stronger than condition B.2, by Lemma 5 we have \(a_k - a_{k+1} < 8b_k^2\kappa^3\). Combining with \(|b_{k} - |b_{k+1}| > |a_k|b_{k}/\kappa\), we have
\[
\begin{align*}
\frac{a_k - a_{k+1}}{|b_{k+1}|} &< \frac{8b_k^2\kappa^3}{|b_{k+1}|} \\
&= \frac{|b_{k+1}|\kappa^2}{|a_k|} \\
&< \frac{1}{2\sqrt{2}}\sqrt{|a_k|\kappa^2} \\
&= 2\sqrt{2}|a_k|^{-\frac{1}{2}}\kappa^2 \\
&< 2\sqrt{2}(\frac{1}{10}\kappa^3)^{-\frac{1}{2}}\kappa^2 \\
&< 8\sqrt{2}\kappa.
\end{align*}
\]

Since the inductive hypothesis gives \((a_0 - a_k)/(|b_0| - |b_1|) < 8\sqrt{2}\kappa\), it follows by the median inequality that \((a_0 - a_{k+1})/(|b_{k}| - |b_{k+1}|))/8\sqrt{2}\kappa\).

Thus we have shown \(P(k) \rightarrow P(k + 1)\), and by induction we know \(P(k)\) holds for any \(k \in \mathbb{N}\). Now we can wrap up the convergence analysis leveraging this property.

Since for all \(t, |b_t| \leq |b_0|(1 - \frac{1}{10}(1 + 2\delta))^{k}\), for any \(\epsilon > 0\) we may pick \(T > \log(1 - \frac{1}{10}(1 + 2\delta))\epsilon/|b_0|\) such that for all \(t > T, |b_t| < \epsilon\). Note that since \(|b_0| < \frac{1}{8}\kappa^2 < 1\) and \(1 - \frac{1}{10}(1 + 2\delta)\), we have
\[
T < \log(1 - \frac{1}{10}(1 + 2\delta))\epsilon/|b_0| < \frac{\log(\epsilon)}{\log(1 - \frac{1}{10}(1.08))} < 25\log(\epsilon^{-1}).
\]

For the region of final convergence, for any \(t\) we know that from \(P(t)\) that \(a_0 - a_t \in [0, 8\sqrt{2}\kappa(|b_0| - |b_t|))\), so we have \(a_0 > a_T > -8\sqrt{2}\kappa|b_t|\). Since we know \(|b_0| < \frac{1}{8}\kappa^2\) and \(a_0 > -\frac{1}{8}\kappa^3\) by initialization, it follows that \(a_T > -\frac{1}{8} - \sqrt{2}\kappa^2 > -\frac{5}{8}\kappa^3\). The upper bound of \(a_T < -\frac{1}{10}(1 + 2\delta)\kappa^3 < \frac{1}{16}\kappa^3\) is trivial since \(a\) is monotonically decreasing.

Thus in summary we have shown that for any \(\epsilon > 0\), there exists some \(T < 25\log(\epsilon^{-1})\) such that for all \(t > T, |b_t| < \epsilon\) and \(a_T \in (-\frac{5}{4}\kappa^3, -\frac{1}{10}\kappa^3)\).
B.6 Proof of Theorem 3.1 and its Corollaries

With all the lemmas ready, we may now prove Theorem 3.1 and its corollaries.

We first restate Theorem 3.1 here.

**Theorem 3.1** (Sharpness Concentration). For a large enough absolute constant $K$, suppose $\kappa < \frac{1}{2000\sqrt{2}}K^{-1}$, and the initialization $(a_0, b_0)$ satisfies $a_0 \in (12\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1})$ and $b_0 \in (-K^{-1}, -K^{-1}) \setminus \{0\}$. Consider the GD trajectory characterized in Eq. (6) with fixed step size $\kappa^2$ from $(a_0, b_0)$, for any $\epsilon > 0$ there exists $T = \mathcal{O}(K^{-2}\kappa^{-\frac{7}{2}} + \log(\epsilon^{-1}) + \log(|b_0|^{-1})\kappa^{-\frac{7}{2}})$ such that for all $t > T$, $|b_t| > \epsilon$ and $a_t \in (-\frac{5}{2}\kappa^3, \frac{1}{10}\kappa^3)$.

The proof for the main theorem is very simple after we have all the lemmas as discussed above.

**Proof of Theorem 3.1.** We consider any initialization $(a_0, b_0)$ satisfying $a_0 \in (12\kappa^2, \frac{1}{4}K^{-2}\kappa^{-1})$ and $b_0 \in (-K^{-1}, -K^{-1}) \setminus \{0\}$. We abuse the notation to let $a_t$ and $b_t$ be the value of $a$ and $b$ after the $t$-th two step update from $a_0$ and $b_0$.

If $|b_0| \geq 2\sqrt{a_0\kappa}$, then by Lemma 8 there exists some $\tau_1 < \kappa^{-4}$ such that $a_{\tau_1} \in (2\kappa^2\frac{1}{4}K^{-2}\kappa^{-1})$ and $b_{\tau_1} \in (\sqrt{a_{\tau_1}\kappa}, 2\sqrt{a_{\tau_1}\kappa})$. If $|b_0| \leq \frac{1}{2}\sqrt{|a_0\kappa|}$, by Lemma 9 there exists some $\tau_2 < \frac{1}{2}\log(|b_0|^{-1})\kappa^{-\frac{7}{2}}$ such that $|b_{\tau_2}| \in (\frac{1}{2}\sqrt{a_{\tau_2}\kappa}, \frac{1}{2}\sqrt{a_{\tau_2}\kappa})$ and $a_{\tau_2} \in (2\kappa^2\frac{1}{4}K^{-2}\kappa^{-1})$. Thus there exists some $T_1 = \mathcal{O}(\kappa^{-4} + \log(|b_0|^{-1})\kappa^{-\frac{7}{2}})$ such that $a_{T_1} \in (2\kappa^2\frac{1}{4}K^{-2}\kappa^{-1})$ and $b_{T_1} \in (\frac{1}{2}\sqrt{a_{T_1}\kappa}, 2\sqrt{a_{T_1}\kappa})$.

Now by Lemma 11 and Corollary B.3, we know that there exists some $\tau_3 \leq 400\kappa^{-1}$ such that within $\tau_3$ two-step updates from $(a_{T_1}, b_{T_1})$ we have $a_{T_1 + \tau_3} \in (\frac{1}{2}\kappa^2, 2\kappa^2)$ and $b_{T_1 + \tau_3} \in (\frac{1}{4}\sqrt{a_{T_1+\tau_3}\kappa}, 2\sqrt{a_{T_1+\tau_3}\kappa})$. Let $T_2 = T_1 + \tau_3$.

This completes phase 1 of convergence.

For phase 2, since $a_{T_2} \in (\frac{1}{2}\kappa^2, 2\kappa^2)$ and $|b_{T_2}| \in (\frac{1}{2}\sqrt{a_{T_2}\kappa}, 2\sqrt{a_{T_2}\kappa})$, by Lemma 13, there exists $\tau_4 < |a_{T_2}|\kappa^{-\frac{7}{2}} < 4\kappa^{-6}$ such that within $\tau_4$ steps from $(a_{T_2}, b_{T_2})$, we have $a_{T_2 + \tau_4} \in (\frac{1}{2}\kappa^2, 2\kappa^2)$ and $|\xi_{T_2 + \tau_4}| < \frac{1}{8}\kappa^4$ where we fixed $\delta = 0.04$. Let $T_3 = T_2 + \tau_4$.

After the residual $|\xi|$ decreases to less than $\frac{1}{8}\delta\kappa^4$ with $T_3$ two-step updates, by Lemma 14 and Corollary B.6 there exists some $\tau_5 < 48\delta\kappa^{-2}$ such that $a_{T_3 + \tau_5} \in (-\frac{1}{2}(1-3\delta)\kappa^3, -\frac{1}{10}(1+2\delta)\kappa^3)$ while $|\xi_{T_3 + \tau_5}| < \frac{1}{8}\delta\kappa^4$. Let $T_4 = T_3 + \tau_5$.

Finally, by Lemma 15 we have that starting from $(a_{T_4}, b_{T_4})$, there exists some $\tau_6 < 25\log(\epsilon^{-1})$ that for any $t > T_4 + \tau_6$, $|b_t| > \epsilon$ and $a_t \in (-\frac{5}{2}\kappa^3, \frac{1}{10}\kappa^3)$. Thus we have the trajectory converging to some minima with $a \in (-\frac{5}{2}\kappa^3, \frac{1}{10}\kappa^3)$.

Finally we bound the total number of steps required for convergence. Since $|a_0| \leq \frac{1}{4}K^{-2}\kappa^{-1}$, we have $\tau_3 < \frac{1}{4}K^{-2}\kappa^{-\frac{7}{2}}$. Moreover, since $\kappa < K^{-1}$, we have $\kappa^{-4} = \mathcal{O}(K^{-2}\kappa^{-\frac{7}{2}})$. Since $T_3 = T_1 + \tau_3 + t_4 + \tau_5 + \tau_6$, we have $T = \mathcal{O} \left(K^{-2}\kappa^{-\frac{7}{2}} + \log(|b_0|^{-1})\kappa^{-\frac{7}{2}} + \log(\epsilon^{-1}) \right)$. (104)

This completes the proof of the theorem.

B.6.1 Proof of Corollary 3.1

Before we proceed to prove Corollary 3.1, we first show a simple lemma on the approximixy of $x$ and $c(x, y) \triangleq \sqrt{x^2 - y^2}$ when $x$ is large and $|1-xy|$ is small. Recall that $c$ was previously defined in Eq. (27) and the $(a, b)$ coordinate that we have been focusing on is the offset from the $\kappa^2$-EoS minima in the $(c, d)$ coordinate.

**Lemma 16** (Approximixy of $c$ to $x$). For any large constant $K > 512$, fix any $\kappa < \frac{1}{2000\sqrt{2}}K^{-1}$. For any $x \in (\frac{3}{2}\kappa^{-1}, 2\kappa^{-1})$ and any $y$ such that $|1-xy| < K^{-1}$, we have $c(x, y) \triangleq \sqrt{x^2 - y^2} \in (x - 32\kappa^3, x)$.

**Proof of Lemma 16.** Since $xy < 1 + K^{-1}$ and $x > \frac{3}{2}\kappa^{-1}$, we must have $y < 2(1 + K^{-1})\kappa < 2\sqrt{2}\kappa$, where the last step holds since we assumed $K > 512$. Meanwhile $1-xy < K^{-1}$ also implies $xy > 1 - K^{-1} > 0$, so $y > 0$. Thus we have

$$c(x, y) = \sqrt{x^2 - y^2} > \sqrt{x^2 - (2\sqrt{2}\kappa)^2} = x\sqrt{1 - 8\kappa^2x^2} > x\sqrt{1 - 8\kappa^2(2\kappa^2)} > x(1 - 16\kappa^4).$$ (105)
where the last two inequality holds since \( x > \frac{\sqrt{2}}{2} \kappa^{-1} \) and \( \sqrt{x} > x \) when \( x \in (0, 1) \). Thus \( c(x, y) > x - 16xk^4 > x - 32\kappa^3 \) since we assume \( x < 2\kappa^{-1} \). Since \( y > 0 \), \( \sqrt{x^2 - y^2} < x \), so \( c(x, y) \in (x - 32\kappa^3, x) \).  

Now we can proceed to proving Corollary 3.1. We first restate the result here:

**Corollary 3.1** (Sharpness Concentration under \((x, y)\)-Parameterization). For a large enough absolute constant \( K \), suppose \( \eta < \frac{1}{20000}K^{-2} \), and the initialization \((x_0, y_0)\) satisfies \( x_0 \in (\bar{x} + 13\eta^\frac{2}{3} + \bar{x} + \frac{1}{2}K^{-2}\eta^{-\frac{1}{2}}) \) and \( |x_0y_0 - 1| \in (0, K^{-1}) \) where \((\bar{x}, \bar{y})\) is the \( \eta \)-EoS minima defined in Definition 1. The GD trajectory characterized in Eq. (2) with fixed step size \( \eta \) from \((x_0, y_0)\) will converge to a global minimum with sharpness \( \lambda \in (\frac{2}{\eta} - \frac{2000}{3^2} \eta, \frac{2}{\eta}) \).

**Proof of Corollary 3.1.** Following the convergence proof for Theorem 3.1, to prove this corollary we only need to show that all initializations \( x_0, y_0 \) satisfies the initialization condition of Theorem 3.1 after re-parameterized to \((a, b)\), and the sharpness \( \lambda \) of the minima will satisfy \( \lambda \in (\frac{2}{\eta} - \frac{2000}{3^2} \eta, \frac{2}{\eta}) \).

We first check the initialization in the \((x, y)\) coordinate satisfies the initialization condition in Theorem 3.1. Due to the different contexts, we will use \( \kappa = \sqrt{\eta} \) and \( \eta \) itself interchangeably.

Recall from Eq. (23) that \( \bar{x} = \frac{\sqrt{2}}{2}((-4 + \eta^{-2})^{\frac{1}{2}} + \eta^{-1})^{\frac{1}{3}} \). It is not hard to check that \( \bar{x} > \frac{\sqrt{2}}{2} \kappa^{-1} \) and \( \bar{x} < \kappa^{-1} \) where \( \kappa = \sqrt{\eta} \). Since \( |x_0y_0 - 1| < K^{-1} \) as required by the initialization, from Lemma 16 we have \( c_0 \triangleq c(x_0, y_0) \in (x_0 - 32\kappa^3, x_0) \). By the same reasoning we also have \( \bar{c} \triangleq c(\bar{x}, \bar{y}) \in (\bar{x} - 32\kappa^3, \bar{x}) \). Thus \( x_0 > \bar{x} + 13\kappa^\frac{2}{3} \kappa^3 \) implies \( c_0 > \bar{c} + 13\kappa^{\frac{2}{3}} + 32\kappa^3 \). Since we assume \( \kappa < \frac{1}{20000}K^{-2} \) where \( K > 512, 32\kappa^3 < \kappa^\frac{2}{3} \), and hence \( c_0 > \bar{c} + 12\kappa^{\frac{2}{3}} \). Therefore \( a_0 \triangleq a(c_0) - \bar{c} > 12\kappa^{\frac{2}{3}} \).

On the other end, since \( \bar{x} < \kappa^{-1} \) as shown above, we have \( \bar{x} + \frac{1}{2}K^{-2} \kappa^{-1} < 2\kappa^{-1} \). So we can again apply Lemma 16 so that \( c_0 < c(\bar{x} + \frac{1}{2}K^{-2} \eta^{-\frac{1}{2}}, y_0) \). Since \( \bar{x} > \bar{x} - 32\kappa^3 \), we have \( c_0 < \bar{c} + \frac{1}{2}K^{-2} \eta^{-\frac{1}{2}} \). The last step holds since \( 32\kappa^3 < K^{-2} \eta^{-\frac{1}{2}} \). Therefore \( a_0 \triangleq a(c_0) - \bar{c} < \frac{1}{2}K^{-2} \eta^{-\frac{1}{2}} \). Since \( |b_0| = |1 - xy| \in (0, K^{-1}) \) by construction, we know \( (a_0, b_0) \) satisfies the initialization condition of Theorem 3.1, and we can have the trajectory converging to a global minima with \( a \in [-\frac{a}{3}, -\frac{b}{10}] \) and \( b = 0 \).

Now we show that for global minima with satisfies \( a_k \in [-\frac{5}{3}, -\frac{1}{10}] \) and \( b_k = 0 \), the sharpness \( \lambda \) satisfies \( \lambda \in (\frac{2}{\eta} - \frac{2000}{3^2} \eta, \frac{2}{\eta}) \).

Recall from Eq. (3) that the sharpness of \((x, y)\) near the global minima is given by

\[
\lambda = \frac{1}{2} \left( (x^2 + y^2) (3\gamma^2 - 1) + \sqrt{(x^2 + y^2)^2(1 - 3\gamma^2)^2 + 4\gamma^2(3 - 10\gamma^2 + 7\gamma^4)} \right)
\]

(106)

where \( \gamma \triangleq xy \). When \((x, y)\) is a global minima, \( \gamma = 1 \), and Eq. (106) reduces to

\[
\lambda = \frac{1}{2} \left( (x^2 + y^2) (3 - 1) + \sqrt{(x^2 + y^2)^2(1 - 3)} \right)
\]

\[
= \frac{1}{2} (2(x^2 + y^2) + 2(x^2 + y^2))
\]

\[
= 2(x^2 + y^2)
\]

\[
= 2\sqrt{x^2 + y^2}^2
\]

\[
= 2\sqrt{4 + (x^2 - y^2)^2}
\]

\[
= 2\sqrt{4 + \sqrt{x^2 - y^2}}^4
\]

\[
= 2\sqrt{4 + c^4}.
\]

(107)

Since \( c = (\kappa^{-4} - 4)^{\frac{1}{2}} + a \), where \( a \in [-\frac{5}{3}\kappa^3, -\frac{10}{3}\kappa^3] \), we have \( c < (\kappa^{-4} - 4)^{\frac{1}{2}} \) and hence \( \lambda = 2\sqrt{4 + c^4} < 2\sqrt{4 + \kappa^{-4} - 4} = 2\kappa^{-2} = \frac{2}{\eta} \).  

40
Now we prove the lower bound for $\lambda$. Follow from $c > (\kappa^{-4} - 4)^{\frac{1}{2}} - \frac{5}{3} \kappa^3$, we have

$$c^4 > \left((\kappa^{-4} - 4)^{\frac{1}{2}} - \frac{5}{3} \kappa^3\right)^4$$

$$= \left((\kappa^{-4} - 4)^{\frac{1}{2}}(\kappa^{-4} - 4)^{-\frac{1}{2}} - \frac{5}{3} \kappa^3(\kappa^{-4} - 4)^{-\frac{1}{2}}\right)^4(\kappa^{-4} - 4)$$

$$= \left(1 - \frac{5}{3} \kappa^3(\kappa^{-4} - 4)^{-\frac{1}{2}}\right)^4(\kappa^{-4} - 4)$$

$$\geq \left(1 - \frac{20}{3} \kappa^3(\kappa^{-4} - 4)^{-\frac{1}{2}}\right)(\kappa^{-4} - 4)$$

$$= \kappa^{-4} - 4 - \frac{20}{3} \kappa^3(\kappa^{-4} - 4)^{\frac{1}{2}}$$

$$\geq \kappa^{-4} - 4 - \frac{20}{3} \kappa^3$$

$$= \kappa^{-4} - 4 - \frac{20}{3}.$$

Thus

$$\lambda = 2\sqrt{4 + c^4}$$

$$\geq 2\sqrt{4 + \kappa^{-4} - 4 - \frac{20}{3}}$$

$$= 2\sqrt{\kappa^{-4} - \frac{20}{3}}$$

$$= 2\sqrt{1 - \frac{20}{3} \kappa^4 \kappa^{-2}}$$

$$\geq 2\left(1 - \frac{20}{3} \kappa^4\right) \kappa^{-2}$$

$$= 2\kappa^{-2} - \frac{20}{3} \kappa^2 = \frac{2}{\eta} - \frac{20}{3} \eta.$$

Hence in conclusion, the converging minima has sharpness $\lambda \in \left(\frac{2}{\eta} - \frac{20}{3} \eta, \frac{2}{\eta}\right)$, which completes the proof for the corollary.

B.6.2 Proof of Corollary 3.2

Before proving Corollary 3.2, we first show a simple lemma on the approximilarity of $\bar{x}$ and $\kappa^{-1}$ where $\bar{x}$ is the $x$-coordinate for the $\kappa^3$-EoS minima.

**Lemma 17** (Approximilarity of $\bar{x}$ and $\kappa^{-1}$). For any large constant $K > 512$, fix any $\kappa < \frac{1}{2000\sqrt{2}} K^{-1}$. With $\bar{x} \triangleq \frac{1}{\sqrt{2}}((-4 + \eta^{-2})^{\frac{1}{2}} + \eta^{-1})^{\frac{1}{2}}$, we have $|\bar{x} - \kappa^{-1}| < 36\kappa^3$.

**Proof of Lemma 17.** Since the condition for $\kappa$ is identical to that of Lemma 16, we have $|\bar{x} - \bar{c}| < 32\kappa^3$ from Lemma 16 where $\bar{c} = (\kappa^{-4} - 4)^{\frac{1}{2}}$ from the calculation in Appendix B.1. Note that

$$\bar{c} = (\kappa^{-4} - 4)^{\frac{1}{2}} = \kappa^{-1}(1 - 4\kappa^{-4})^{\frac{1}{2}} > \kappa^{-1}(1 - 4\kappa^{-4}) = \kappa^{-1} - 4\kappa^{-3}.$$

It is straightforward that $\bar{c} < \kappa^{-1}$, so $|\bar{c} - \kappa^{-1}| < 4\kappa^3$. Combining with $|\bar{x} - \bar{c}| < 32\kappa^3$, we have $|\bar{x} - \kappa^{-1}| < 36\kappa^3$, which completes the proof. \qed

Now we can proceed to prove Corollary 3.2. We first restate the corollary.

**Corollary 3.2** (Sharpness Adaptivity). For a large enough constant $K$, fix any $\alpha < \frac{1}{2000\sqrt{2}} K^{-1}$. For all initialization $(x_0, y_0)$ in the region characterized by

$$x_0 \in (\alpha^{-1} \pm \frac{1}{\sqrt{2}} K^{-2} \alpha^{-1}, \alpha^{-1} + \frac{1}{\sqrt{2}} K^{-2} \alpha^{-1})$$

and $|y_0| \in (0, K^{-1})$, the GD trajectory from $(x_0, y_0)$ characterized by Eq. (2) with any step size $\eta \in (\alpha^2 - \frac{1}{\sqrt{2}} K^{-2} \alpha^2, \alpha^2)$ will converge to a minima with sharpness $\lambda \in \left(\frac{2}{\eta} - \frac{20}{3} \eta, \frac{2}{\eta}\right)$.

**Proof of Corollary 3.2.** To prove this corollary, we only need to show that for all $\eta$ in the required range, the initialization region characterized by the corollary is a subset of the initialization region required by Corollary 3.1 for that particular $\eta$.

For the ease of derivation, we will use $\kappa^2$ to substitute for $\eta$. Since we are dealing with different step sizes, we augment our notation to let $(\bar{x}_{\kappa^2}, \bar{y}_{\kappa^2})$ denote the $\kappa^2$-EoS minimum. Note that the condition for $y_0$, namely
\[|x_0y_0 - 1| \in (0, K^{-1}) \] is identical to what is required by Corollary 3.1 so we only need to show for any learning rate \( \kappa^2 \in (\alpha^2 - \frac{1}{10} K^{-2} \alpha^2, \alpha^2) \),

\[
(\alpha^{-1} + \frac{1}{15} K^{-2} \alpha^{-1} + \frac{1}{6} K^{-2} \alpha^{-1}) \subseteq (\tilde{x}_{\kappa^2} + 13\kappa^2 + \frac{1}{5} K^{-2} \kappa^{-1}). \tag{111}
\]

We will first show \( \tilde{x}_\eta + 13\kappa^2 < \alpha^{-1} + \frac{1}{10} K^{-2} \alpha^{-1} \).

Since \( \kappa^2 > \alpha^2 - \frac{1}{10} K^{-2} \alpha^2 \), we have \( \kappa > (1 - \frac{1}{10} K^{-2}) \frac{\kappa}{\alpha} > (1 - \frac{1}{10} K^{-2} + \frac{1}{30}) \alpha = (1 - \frac{1}{10} K^{-2}) \alpha \) where the last inequality holds since we may assume \( K > 512 \). Taking the multiplicative inverse, we have \( \kappa^{-1} < (1 - \frac{1}{10} K^{-2})^{-1} \alpha^{-1} \).

Now note that since \( K^{-1} < 1 \), \( (1 + \frac{1}{15} K^{-2})(1 - \frac{1}{10} K^{-2}) = 1 + \frac{1}{15} K^{-2} - \frac{1}{285} K^{-4} > 1 \), so \( (1 - \frac{1}{10} K^{-2})^{-1} < 1 + \frac{1}{15} K^{-2} \) and hence \( \kappa^{-1} < (1 - \frac{1}{10} K^{-2})^{-1} \alpha^{-1} < (1 + \frac{1}{15} K^{-2}) \alpha^{-1} \). From Lemma 17 we know \( \tilde{x}_{\kappa^2} < \kappa^{-1} + 36\kappa^3 \), so

\[
\tilde{x}_{\kappa^2} + 13\kappa^2 < \kappa^{-1} + 36\kappa^3 + 13\kappa^2 < (1 + \frac{1}{15} K^{-2}) \alpha^{-1} + 36\kappa^3 + 13\kappa^2. \tag{112}
\]

Note that since \( \kappa < \alpha < \frac{1}{2000\sqrt{2}} K^{-1} \) where \( K > 512 \), we have

\[
36\kappa^3 + 13\kappa^2 < \kappa^2 < \frac{1}{8000000} K^{-2} < \frac{1}{480} K^{-2} < (\frac{1}{15} - \frac{1}{16}) K^{-2} \alpha^{-1}. \tag{113}
\]

Thus combining with \( \tilde{x}_{\kappa^2} + 13\kappa^2 < (1 + \frac{1}{15} K^{-2}) \alpha^{-1} + 36\kappa^3 + 13\kappa^2 \), we have

\[
\tilde{x}_{\kappa^2} + 13\kappa^2 < (1 + \frac{1}{15} K^{-2}) \alpha^{-1} + (\frac{1}{15} - \frac{1}{16}) K^{-2} \alpha^{-1} < \alpha^{-1} + \frac{1}{10} K^{-2} \alpha^{-1}. \tag{114}
\]

The other side is much simpler to show. Since \( \kappa < \alpha \), we have \( \kappa^{-1} > \alpha^{-1} \). From Lemma 17 we have \( \tilde{x}_{\kappa^2} > \kappa^{-1} - 36\kappa^3 \), so \( \tilde{x}_{\kappa^2} + \frac{1}{5} K^{-2} \kappa^{-1} > \alpha^{-1} - 36\kappa^3 + \frac{1}{5} K^{-2} \alpha^{-1} \). From Eq. (113) we know \( 36\kappa^3 < \frac{1}{800} K^{-2} < \frac{1}{30} K^{-2} \alpha^{-1} = (\frac{1}{5} - \frac{1}{6}) K^{-2} \alpha^{-1} \). Therefore \( \tilde{x}_{\kappa^2} + \frac{1}{5} K^{-2} \kappa^{-1} > \alpha^{-1} + \frac{1}{5} K^{-2} \alpha^{-1} \). This concludes the proof for the corollary. \( \square \)
B.7 Other Auxiliary Lemmas

B.7.1 Constant bound on $R_\delta(\kappa)$

Lemma 18. For all $\kappa < 0.1$, for all $(a, b) \in (-\kappa^{-1}, \kappa^{-1}) \times (-1, 1)$, there exists some absolute constant $K$ independent of $a, b, \kappa$ such that

$$\delta \triangleq \sqrt{4\kappa^4 (1 + b)^2 + \left(\alpha \kappa + (1 - 4\kappa^4)^{\frac{1}{4}}\right)^4} = 1 + 2\alpha a + a^2 \kappa^2 + 2b(2 + b)\kappa^4 + K\kappa^5. \quad (115)$$

Proof of Lemma 18. By explicitly computing the derivatives for $\delta$ with respect to $\kappa$, we know that $\delta$ is $C^6$ with respect to $\kappa$ and have the Taylor expansion

$$\delta = 1 + 2\alpha a + a^2 \kappa^2 + 2b(2 + b)\kappa^4 + R_\delta(\kappa)\kappa^5. \quad (116)$$

where $R_\delta(\kappa)$ is the Lagrangian remainder that $R_\delta(\kappa) = \frac{\partial^6 \delta}{\partial \kappa^6}(x)/120$ for some $x \in [0, \kappa]$. To prove the lemma we only need to bound the $R_\delta$ by some absolute constants. For simplicity of notation, denote $\alpha \triangleq (1 - 4x^4)\kappa$, $\beta = \alpha + ax$, $\gamma = 1 + b$, and $\phi = (4\gamma^2x^4 + \beta^4)^{\frac{1}{2}}$. Moreover, let

\[
\begin{align*}
\rho_1 &= \alpha - 4\kappa^3, \\
\rho_2 &= -\frac{12\kappa^2}{\alpha^3} - \frac{48\kappa^6}{\alpha^7}, \\
\rho_3 &= -\frac{24\kappa}{\alpha^3} - \frac{432\kappa^5}{\alpha^7} - \frac{1344\kappa^9}{\alpha^{11}}, \\
\rho_4 &= -\frac{24}{\alpha^3} - \frac{2448\kappa^4}{\alpha^7} - \frac{24192\kappa^8}{\alpha^{11}} - \frac{59136\kappa^{12}}{\alpha^{15}}, \\
\rho_5 &= -\frac{10080\kappa^3}{\alpha^7} - \frac{262080\kappa^7}{\alpha^{11}} - \frac{1774080\kappa^{11}}{\alpha^{15}} - \frac{3548160\kappa^{15}}{\alpha^{19}}.
\end{align*}
\]

By doing some tedious calculation we have

\[
\frac{\partial^5 \delta}{\partial \kappa^5}(x) = \frac{105 (16\gamma^2 \kappa^3 + 4\beta^3 \rho_1)^5}{32 \phi^9} - \frac{75 (16\gamma^2 \kappa^3 + 4\beta^3 \rho_1)^3}{8 \phi^7} (48\gamma^2 \kappa^2 + 12\beta^2 \rho_1^2 + 4\beta^3 \rho_2) \\
+ \frac{45 (16\gamma^2 \kappa^3 + 4\beta^3 \rho_1)}{8 \phi^5} \left(48\gamma^2 \kappa^2 + 12\beta^2 \rho_1^2 + 4\beta^3 \rho_2\right)^2 \\
+ \frac{15 (16\gamma^2 \kappa^3 + 4\beta^3 \rho_1)^3}{4 \phi^3} \left(96\gamma^2 \kappa^2 + 24 \beta^2 \rho_1^2 + 36 \beta^3 \rho_1 \rho_2 + 4\beta^3 \rho_1\right) \\
- \frac{5 (48\gamma^2 \kappa^2 + 12\beta^2 \rho_1^2 + 4\beta^3 \rho_2)}{2 \phi^3} \left(96\gamma^2 \kappa^2 + 24 \beta^2 \rho_1^2 + 144 \beta^2 \rho_2^2 + 36 \beta^3 \rho_2^2 + 48 \beta^2 \rho_2 \rho_1 + 4\beta^3 \rho_4\right) \\
- \frac{5 (16\gamma^2 \kappa^3 + 4\beta^3 \rho_1)}{2 \phi^3} \left(96\gamma^2 \kappa^2 + 24 \beta^2 \rho_1^2 + 144 \beta^2 \rho_2^2 + 36 \beta^3 \rho_2^2 + 48 \beta^2 \rho_2 \rho_1 + 4\beta^3 \rho_4\right) \\
+ \frac{240 \rho_1^2 \rho_2 + 360 \beta \rho_1 \rho_2^2 + 240 \beta \rho_1 \rho_3 + 120 \beta \rho_2 \rho_3 + 60 \beta^2 \rho_1 \rho_4 + 4\beta^3 \rho_5}{2 \phi^3}.
\]

Since $\kappa < 0.1$, we have $\alpha = (1 - 4x^4)\kappa > 0.99$ and $\phi = (4\gamma^2x^4 + \beta^4)^{\frac{1}{2}} > \beta^2 = (\alpha + dx)^2 > \alpha^2 > 0.9$. Thus $\alpha$ and $\phi$ are bounded from below by some constants. Since $\kappa$ is bounded from above, we have $\rho_1, \ldots, \rho_5$ bounded from above by some constants.

Now we give upper bounds for $\beta$ and $\gamma$. Since $|x| < 0.1$, we have $(1 - 4x^4)\kappa^2 \leq 1$. Since $|a| < \kappa^{-1}$, we have $\beta = \alpha + ax < \alpha + ax < \alpha + 1 < 2$. Since $|b| < 1$, we have $\gamma = 1 + b < 2$. Note that it is straightforward from construction that all these terms are positive.

From Eq. (118) we have $\frac{\partial^5 \delta}{\partial \kappa^5}(x)$ as some finite degree polynomial of $\beta, \gamma, \kappa, \rho_1, \ldots, \rho_5$, and $\phi^{-1}$. Since the absolute value for all of these terms are bounded above by some constants independent of $x$, we have $\left|\frac{\partial^5 \delta}{\partial \kappa^5}(x)\right|$ uniformly bounded above by some constant $K$ for all $x \in [0, \kappa]$. This completes the proof of the lemma. \qed
C Theoretical Analysis on Rank-1 Approximation of Isotropic Matrix

In this section we prove the convergence of the vector case.

C.1 Preliminaries

Model: We consider a generalized model from the scalar product case.

\[
\min_{x, y \in \mathbb{R}^d} \frac{1}{4} \| I - x y^\top x y^\top \|^2_F.
\] (119)

The normalization factor \( \frac{1}{4} \) is added to show the equivalence of this rank-1 isotropic matrix factorization problem and the scalar case considered in Appendix B.6. We will show how the equivalence is achieved due to the alignment in the next section.

Update Rule: We use gradient descent to optimize this problem. By computing the closed-form of the gradient, we know the 1-step update of \( x \) and \( y \) follows:

\[
x_{t+1} = x_t + \eta \left[ (x_t^\top y_t) y_t - \frac{1}{2} (x_t^\top y_t) \| x_t \|^2 y_t - \frac{1}{2} (x_t^\top y_t)^2 \| y_t \|^2 x_t \right],
\]
\[
y_{t+1} = y_t + \eta \left[ (x_t^\top y_t) x_t - \frac{1}{2} (x_t^\top y_t) \| x_t \|^2 y_t - \frac{1}{2} (x_t^\top y_t)^2 \| x_t \|^2 x_t \right].
\] (120)

With the gradient descent update above, we can have the dynamics of the following four quantities: \( \| x \|^2, \| y \|^2 \), and \((x^\top y)^2\).

\[
\| x_{t+1} \|^2 = \| x_t \|^2 + 2 \eta \left( (x_t^\top y_t)^2 - (x_t^\top y_t)^2 \| x_t \|^2 \| y_t \| \right)
+ \eta^2 \left( 4(x_t^\top y_t)^2 \| y_t \|^2 + (x_t^\top y_t)^2 \| x_t \|^4 \| y_t \|^2 \right. \\
\left. - 4(x_t^\top y_t)^2 \| x_t \|^2 \| y_t \|^4 - 4(x_t^\top y_t)^4 \| y_t \|^2 \right),
\]
\[
\| y_{t+1} \|^2 = \| y_t \|^2 + 2 \eta \left( (x_t^\top y_t)^2 - (x_t^\top y_t)^2 \| x_t \|^2 \| y_t \| \right)
+ \eta^2 \left( 4(x_t^\top y_t)^2 \| x_t \|^2 + (x_t^\top y_t)^2 \| x_t \|^4 \| y_t \|^2 \right. \\
\left. - 4(x_t^\top y_t)^2 \| x_t \|^2 \| y_t \|^4 - 4(x_t^\top y_t)^4 \| x_t \|^2 \right),
\] (121)

\[
(x_{t+1}^\top y_{t+1})^2 = (x_t^\top y_t)^2 \left( 1 + \eta (\| x_t \|^2 + \| y_t \|^2) (1 - \frac{1}{2} \| x_t \|^2 \| y_t \|^2 - \frac{1}{2} (x_t^\top y_t)^2) \right)
+ \eta^2 (x_t^\top y_t)^2 \left[ 4 (\| x_t \|^2 \| y_t \|^2 - 1)^2 - \| x_t \|^2 \| y_t \|^2 (\| x_t \|^2 \| y_t \|^2 - (x_t^\top y_t)^2) \right] \right)^2.
\] (122)

Furthermore, we define an alignment notation for the variable: \( \xi_t := \| x_t \|^2 \| y_t \|^2 - (x_t^\top y_t)^2 \). By Eq. (122) and Eq. (121), we can derive the following update rule of \( \xi \).

\[
\xi_{t+1} = \xi_t \left( 1 - (x_t^\top y_t)^2 \eta \left( \frac{\| x_t \|^2}{2} + \frac{\| y_t \|^2}{2} + \eta ((2 - \| x_t \|^2 \| y_t \|^2)^2 - \| x_t \|^2 \| y_t \|^2 (x_t^\top y_t)^2) \right) \right)^2.
\] (123)

C.2 Proof of Theorem 3.2

We restate the theorem of the vector case.

Theorem C.1. For a large enough absolute constant \( K \), with all the initialization \((x_0, y_0)\) satisfying \( x_0 \sim \delta_{\nu} \text{Unif}(\mathbb{R}^d), \ y_0 \sim \delta_{\nu} \text{Unif}(\mathbb{R}^d), \delta_{\nu} \delta_{\eta} = \frac{1}{2}, \delta_{\nu} \in \left( \frac{1}{K} - \frac{1}{K^2 \log \nu^{-1}} \right)^\top, \frac{1}{K} - \frac{1}{K^2 \log \nu^{-1}} \right) \), if step size \( \eta < \min \left\{ \frac{1}{K^2 \log \nu^{-1}}, \frac{1}{2K^2 \log \nu^{-1}} \right\} \), and a multiplicative perturbation \( y'_t = y_t (1 + 2K^{-1}) \) is performed

\( y'_t = y_t (1 + 2K^{-1}) \) at time \( t_p \), means at this iteration, we multiply \((1 + 2K^{-1})\) to the vector \( y \).
Lemma 20. (Alignment) Assume \( \alpha \) Here we present the following key lemmas to prove the convergence at the edge of stability. For simplicity, we parameterized dynamics of distance to the manifold of the minimizers; (iv) after entering the feasible region and \( \xi \) after the perturbation gradient descent will re-enter the feasible regime, while at the same time keep a constant (Lemma 22); (iii) To escape from some sharp minima, we add some deterministic perturbation, and we prove that prove the norm of the two vectors \( x, y \) at time \( t \) will decay geometrically after

\[
\| x - y \|_2 = \frac{1}{t} < \epsilon \quad \text{and} \quad \| x \|_2 + \| y \|_2 \in (\frac{1}{2} - \frac{1}{\alpha} \eta, \frac{1}{\alpha} \eta).
\]

In the following analysis, we still use the operator \( O(\cdot) \) to only hides absolute constants, and \( K \) to represent the absolute constant that uniformly upper bounds all the absolute constants of the \( O(\cdot) \) terms. Also \( K > 512 \). We still use the notation of \( \eta \)-EqS minimum \( (\hat{x}, \hat{y}) \) of the scalar case in the vector case.

We first prove some properties of the global minimizers. The following lemma guarantees the alignment of the two vectors \( x, y \) at any global minimizer \( (x, y) \).

**Lemma 19.** (Global minimizers) For all global minimizers \( (x, y) \) of the optimization problem Eq. (119), we have \( x = cy \) for some \( c \in \mathbb{R} \), and \( \|x\|\|y\| = 1 \).

**Proof.** We directly consider the objective \( \| I - xy^Txy^T \|_F^2 \).

\[
\| I - xy^Txy^T \|_F^2 = \text{Tr}((I - xy^Txy^T)^T(I - xy^Txy^T)) = \text{Tr}(I - xy^Txy^T) = d - 2(x^Ty)^2 + (x^Ty)^2\|x\|\|y\| = d - 1 + ((x^Ty)^2 - 1)^2 - (x^Ty)^2\|x\|\|y\| = d - 1 - \|x\|\|y\|
\]

The global minimizer takes value \( \frac{d-1}{2} \) and the equality holds when

\[
((x^Ty)^2 - 1)^2 - (x^Ty)^2\|x\|\|y\| = 0
\]

which is equivalent to \( x = cy \) for some \( c \in \mathbb{R} \), and \( \|x\|\|y\| = 1 \).

Now we consider the formal proof. To prove the theorem we have four steps: (i) we prove the two vectors \( x, y \) will decay geometrically after \( T = O(-\log(\eta) - \log(\delta_0) + \log(d)) \) time (Lemma 20, Lemma 21); (ii) we prove the norm of the two vectors \( \|x\|, \|y\| \) will satisfy the initialization condition in \( T < 6K^3 + 4K \) time (Lemma 22); (iii) To escape from some sharp minima, we add some deterministic perturbation, and we prove that after the perturbation gradient descent will re-enter the feasible regime, while at the same time keep a constant distance to the manifold of the minimizers; (iv) after entering the feasible region and \( \xi \) is small enough, the re-parameterized dynamics of \( \|x\| \) and \( \|y\| \) can be captured by the scalar dynamics (Lemma 25). Then, we can reduce this vector case to the scalar product case and finish the proof.

Here we present the following key lemmas to prove the convergence at the edge of stability. For simplicity, we denote \( \alpha(t) := \eta(\|x_t\|^2 + \|y_t\|^2) \).

**Lemma 20.** (Alignment) Assume \( 0 < \alpha(0) < \frac{1}{4} \), \( 0 < x^T_t y_0 < \|x_0\||y_0| \leq \frac{1}{2} \eta, \eta < 0.01 \). Then as long as

\[
-\frac{1}{100} < \alpha(t) < \frac{1}{2} \quad \text{for all} \quad t \in [0, t_1] \quad \text{for some} \quad t_1, \quad \text{then for all} \quad t \in [0, t_1 + 1], \quad 0 < (x^T_t y_t)^2 < \frac{13}{10} \quad \text{and} \quad \xi_{t+1} < \xi_t.
\]

Moreover, there exists some \( t_0 < \log_{\frac{1}{200}}(\frac{1}{y_0}) \), for all \( t \in [0, t_1 + 1], \quad 7/5 < (x^T_t y_t)^2 < \frac{13}{10} \) and \( \xi_{t+1} < 0.7 \xi_t \).

**Proof.** We use induction. For iteration 0, the induction basis holds. Now we consider iteration \( t+1 \) when assuming the holds condition at iteration 0, 1, 2, ..., \( t \).

Consider Equation (122). We denote \( c_t = (x^T_t y_t)^2 \). And from the induction hypothesis, \( \xi_t < \|x_0\|^2\|y_0\|^2 < 1/4 \) for all time. Thus \( \|x_t\|^2\|y_t\|^2 = c_t + \xi_t < \frac{1}{20} \). Then we have

\[
c_{t+1} < c_t(1 + (1 + \alpha(t)(1 - c_t) + 20\eta^2)^2 < c_t(\frac{1001}{500} + \alpha(t) - (1 + \alpha(t))c_t)^2.
\]

Since \( 0 < c_t < 13/10 \) and \( -0.01 \leq \alpha < 1/8 \), this function takes maximal value when \( c_t = \frac{1001}{1500(1+\alpha(t))} \).

\[
c_{t+1} < c_t\left(\frac{1001}{500} + \alpha(t) - (1 + \alpha(t))c_t\right)^2 \leq \frac{1001}{1500(1+\alpha(t))}\left(\frac{1001}{500} + \alpha(t)\right) < \frac{13}{10}
\]

The lower bound 0 of \( c_t \) is straightforward since we have

\[
c_{t+1} > c_t(1 + (1 + \alpha(t))(1 - c_t - \xi_t/2))^2 > 0
\]

[45]
due to $c_t + \xi_t/2 < 31/20$ and $-0.01 < \alpha(t) < 1/8$.

Then we consider the tighter bound and a faster decaying rate after some $t_0$. If $c_0 > 7/20$ and the lower bound holds at $t = 0$, then $t_0 = 0 < \log_2(\sum_{i=0}^2 \|x_0\|/2)$. Then we begin the induction from $t_0$. Consider $t \geq t_0$,

$$\xi_t < \xi_0(-1 + (x_0^T y_0)^2 + \|y_0\|^2/2)^2 < \frac{1}{4}$$

and the lower bound of $c_{t+1}$ becomes (since $7/20 < c_t < 1.3$)

$$c_{t+1} > \min\{c_t(1 + (1 + \alpha(t))(1 - c_t - \xi_t/2))^2, c_t(1 + (1 - c_t - \xi_t/2))^2\}$$

$$> \min\{c_t(1 + (9/8(1 - c_t - 1/8))^2, c_t(1 + (1 - c_t - 1/8))^2\}$$

$$> 7/20.$$

The last inequality is because of the monotonic decrement of the last function, which takes minimal value at $c_t = \frac{13}{10}$. This proves the first statement.

Then consider the alignment dynamics by Equation (123). The factor can be bounded as follow:

$$(-1 + (x^T y)^2_2)^2(\|x\|^2/2 + \|y\|^2/2 + \eta((2 - \|x\|^2\|y\|^2)^2 - \|x\|^2\|y\|^2(x^T y)^2)/4)^2$$

$$< \max\{1 - \frac{7}{20} \times 1/2 + 100\eta^2, -1 + \frac{3}{2} \times \frac{9}{8} + 10\eta^2\} < 0.7$$

By induction, we finish the proof.

If $c_0 \leq 7/20$, then we prove that $c_t$ will eventually become larger than $7/20$ after some time $t_0$, and then apply the same induction process above to finish the proof.

Still we consider the lower bound of the dynamics of $c_t$. If we have $c_t < 7/20,$

$$c_{t+1} > c_t(1 + (1 - c_t - \xi_t/2))^2 > c_t(1 + (1 - c_t - 1/8))^2 > 2c_t$$

Then it at most takes $t_0 = \lceil \log_2(\frac{7}{20}x_0^Ty_0) \rceil$ to satisfy the condition. Now we finish the proof. 

We first consider the time $\xi$ takes to become smaller than $\eta^2$.

**Lemma 21.** (Alignment convergence time) Suppose all the conditions in Theorem C.1 holds. Then with probability $1 - 2\delta_0 - 2\exp\{-\Omega(d)\}$, there exists some time $T_0 = \log_{0.7}(\eta^2) + \log_2(\frac{2d^4}{512\eta^2}) = O(-\log(\eta) + \log(d) - \log(\delta_0))$ such that $\xi_t < \eta^2$ and $\|x_0\| \in (\tilde{x} + \frac{1}{\sqrt{m}}K^{-2}\eta^{-\frac{1}{2}}, \tilde{x} + \frac{1}{\sqrt{m}}K^{-2}\eta^{-\frac{1}{2}})$ for $t \in [T_0, T_0 + 6K^3 + 4K]$.

**Proof.** We first prove that the bound of $(x^T y)^2$ can be reached with probability $1 - 2\delta_0 - 2\exp\{-\Omega(d)\}$, and meanwhile the alignment $\xi$ begins to shrink after $t_0 = [\log_2(\frac{2d^4}{512\eta^2})]$.

For the initialization, $\delta_x \delta_y = \frac{1}{2}$, and by symmetry we know

$$\Pr[(x^T_0 y_0)^2 < \frac{\delta_0^2}{3d}] = \Pr[x^2 < \frac{\delta_0^2}{15d}]$$

It is equivalent to consider sampling from $\mathcal{N}(0, I)$ and then divide it by its norm. By the initialization condition, we apply the Gaussian concentration bound and Theorem 3.1.1 in Vershynin (2018) and get

$$\Pr[(x^T_0 y_0)^2 < \frac{\delta_0^2}{3d}] < \Pr[x^2 < \delta_0^2] + \Pr[\|x\|^2 < 1.5d] < 2\delta_0 + 2\exp\{-\Omega(d)\}$$

Then with probability $p > 1 - 2\delta_0 - 2\exp\{-\Omega(d)\}$, $\frac{x^2}{\eta^2} \leq (x^T_0 y_0)^2 < \frac{1}{2}$. During $t \in [0, T + 6K^3 + 4K]$, we can apply the first argument in Lemma 20 and induction to prove that $(x^T y)^2 < \frac{14}{10}$ and $0 < \alpha(t) < \frac{11K^2 - 50}{50}$. For $t = 0$, since $\delta_x \in (\tilde{x} + \frac{1}{\sqrt{m}}K^{-2}\eta^{-\frac{1}{2}}, \tilde{x} + \frac{1}{\sqrt{m}}K^{-2}\eta^{-\frac{1}{2}})$, $\frac{1}{\sqrt{m}}K^{-2} < \alpha(0) < \frac{1}{2}K^{-2} < \frac{1}{8}$ and $(x^T_0 y_0)^2 < ||x_0||^2||y_0||^2 = \frac{1}{2} < \frac{14}{10}$. Then we suppose for time $t \in [0, t_1 - 1]$ the statement is correct. By the induction hypothesis, we know for $t \in [0, t_1 - 1]$ the condition of Lemma 20 holds. Therefore, by Lemma 20, for all $t \in [0, t_1], (x^T y)^2 < \frac{13}{10}$. 

46
With the upper bound of $(x_t^* y_t)^2$, the one step movement of $\|x\|^2 + \|y\|^2$ can be bounded:

$$\begin{align*}
\|x_{t+1}\|^2 + \|y_{t+1}\|^2 - \|x_t\|^2 - \|y_t\|^2 &= (\|x_t\|^2 + \|y_t\|^2)(\eta^2 (x_t^* y_t)^2((\|x_t\|^2\|y_t\|^2)^2 - 1)^2 \\
&+ (2 - \frac{3}{4}\|x_t\|^2\|y_t\|^2)(\|x_t\|^2\|y_t\|^2 - (x_t^* y_t)^2)) + 4\eta(x_t^* y_t)^2(1 - \|x_t\|^2\|y_t\|^2) \\
&< \eta \cdot (1 + \alpha(t)) \cdot \frac{3}{10} \cdot (1 + 1) > 2\eta < 5\eta.
\end{align*}$$

For $t < T_0 + 6K^3 + 4K$, the total movement of $\|x_t\|^2 + \|y_t\|^2$ is smaller than $5\eta(T + 6K^3 + 4K)$, and the corresponding movement of $\alpha(t)$ is smaller than $5\eta(T + 6K^3 + 4K) < K^{-2}$ (since $\eta < \min\{\frac{K^{-4}}{2000000}, \frac{K^{-2}}{2000000\log(d) - \log(\delta_0)}\}$).

Thus by induction, $(x_t^* y_t)^2 < \frac{1}{10}$ and $0 < \alpha(t) < \frac{K^{-2}}{2000000} + \frac{K^{-2}}{2000000\log(d) - \log(\delta_0)}$. Then by the second argument of Lemma 20, we have $\frac{7}{20} < (x_t^* y_t)^2 < \frac{13}{10}$ and $\xi_{t+1} < 0.7\xi_t$ for $t > \log_2(\frac{2\log(\delta_0)}{2000000}) = O(\log(d) - \log(\delta_0))$.

After $t = \log_2(\frac{2\log(\delta_0)}{2000000})$, we can calculate the time when $\xi_t < \eta^2$. It needs at most $\log_2(\eta^2) = -O(\log(\eta))$ for $\xi_t$ to become smaller than $\eta^2$. Now we know with $T_0 = \log_2(\eta^2) + \log_2(\frac{2\log(\delta_0)}{2000000}) = O(-\log(\eta) + \log(d) - \log(\delta_0))$, within $t \in [T_0, T_0 + 6K^3 + 4K]$, $\xi_t < \eta^2$ always holds.

On the other hand, we can also have the lower bound of $\|x_t\|^2 + \|y_t\|^2$. The one step movement has the lower bound

$$\begin{align*}
\|x_{t+1}\|^2 + \|y_{t+1}\|^2 - \|x_t\|^2 - \|y_t\|^2 &= (\|x_t\|^2 + \|y_t\|^2)(\eta^2 (x_t^* y_t)^2((\|x_t\|^2\|y_t\|^2)^2 - 1)^2 \\
&+ (2 - \frac{3}{4}\|x_t\|^2\|y_t\|^2)(\|x_t\|^2\|y_t\|^2 - (x_t^* y_t)^2)) + 4\eta(x_t^* y_t)^2(1 - \|x_t\|^2\|y_t\|^2) \\
&< 0 - 2\eta < -5\eta.
\end{align*}$$

So for $t < T_0 + 6K^3 + 4K$, the total decrement of $\|x_t\|^2 + \|y_t\|^2$ is larger than $-5\eta(T_0 + 6K^3 + 4K) > -\frac{K^{-2}}{2000000}\eta^{-\frac{1}{2}}$.

Because $x_t^* y_t \in (\frac{7}{20}, \frac{13}{10})$, $\|y_t\|^2 < \frac{13}{10}/\|x_t\|^2 < \frac{1}{10000} K^{-2}\eta^{-\frac{1}{2}}$. Therefore, $\|x_t\|^2 < \frac{1}{2000000} K^{-2}\eta^{-\frac{1}{2}}$.

After we have the alignment guarantee, we will enter the feasible regime for the scalar case with high probability. Still, we denote $c_t = (x_t^* y_t)^2$.

**Lemma 22. (Feasible regime guarantee) If $\xi_t < \eta^2$, $\eta < \frac{1}{2000000} K^{-4}$, $\frac{1}{1000} < \alpha(t) < \frac{1}{2} K^{-2}$ for all $t \in [t_1, t_1 + 6K^3 + 4K]$, then there exists some $T < 6K^3 + 4K$ such that for all $t \in [t_1 + T, t_1 + 6K^3 + 4K]$, $\|x_t\|^2\|y_t\| - 1 < K^{-1}$.

**Proof.** To prove the statement, we try to prove a stronger statement:

$$c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2}).$$

If this statement holds, because $\xi_t < \eta^2$, the product of the norms are

$$\begin{align*}
\|x_t\|^2\|y_t\|^2 \in (1 - K^{-1}, 1 + K^{-1} - K^{-2} + \eta^2)
\end{align*}$$

So we have $\|x_t\|^2\|y_t\| \in (1 - \frac{2}{K} K^{-1}, 1 + \frac{2}{K} K^{-2})$ and the lemma is proved. So in the rest of the proof, we will prove this stronger statement.

First we prove that there exists some time $t < 4K + 1$ that the square of the inner product $c_t$ will be larger than $1 - K^{-1}$.

If $c_t \in (\frac{7}{20}, 1/2)$, then

$$c_{t+1} > c_t(1 + 1 \times (1 - 1/4 - \eta^2 - 1/4))^2 > \frac{7}{20} \times 1.4^2 > 1/2.$$

Thus $c_t$ will provably enter $c_t > 1/2$ in one step. And if $1/2 < c_t < 1 - K^{-1}$, we have

$$c_{t+1} > c_t(1 + (1 - c_\eta - \eta^2))^2 > c_t(1 + \frac{1}{2} K^{-1}) > c_t + \frac{1}{4} K^{-1},$$

which means it takes at most $4K$ steps for $c_t$ to become larger than $1 - K^{-1}$.
Now we prove if $c_t > 1 - K^{-1}$, then it will take at most $T = 6K^3$ steps s.t. for $t' > t + T$, $c_{t'} \in (1 - K^{-1}, 1 + K^{-1} - K^{-2})$, which finishes the proof. We first prove there exists some $t$, $c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2})$; afterwards we prove that once $c_t$ gets in, it will never get out of the region.

If at first $c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2})$, the proof is done. Otherwise, we suppose $c_t > 1 + K^{-1} - K^{-2}$. Next, we consider the two step dynamics of $c_t$ and prove it will decay by a constant factor every two steps.

First we pick out the relatively small terms, and find out the main part of the two step dynamics. If $\alpha(t) < \alpha_0 < 1/8$, and $1 + K^{-1} - K^{-2} < c_t < 1.3$, we have:

$$c_{t+1} \leq c_t(1 + (1 + \alpha(t))(1 - c_t) + 10\eta^2)^2$$
$$c_{t+1} \geq c_t(1 + (1 + \alpha(t))(1 - c_t) - 2\eta^2)^2$$
$$c_{t+2} \leq c_{t+1}(1 + (1 + \alpha(t+1))(1 - c_{t+1}) + 10\eta^2)^2$$
$$< c_t(1 + (1 + \alpha(t))(1 - c_t) + 10\eta^2)^2(1 + 1 + \alpha(t+1))(1 - c_{t+1}) + 10\eta^2)^2$$

Then we upper bound the difference $\alpha(t + 1) - \alpha(t)$ in one step. Consider the dynamics of $\|x\|^2 + \|y\|^2$. The difference each step is at most

$$\|x'\|^2 + \|y'\|^2 - \|x\|^2 - \|y\|^2 = (\|x\|^2 + \|y\|^2)(\|x\|^2 - \|y\|^2 + 2 - (\|x\|^2\|y\|^2)) + 4\eta(x^T y)^2(1 - \|x\|^2\|y\|^2) < \eta \cdot (1 + \alpha(t)) \cdot \frac{13}{10} \cdot (1 + 1 + 2\eta < 5\eta)$$

Then the corresponding update of $\alpha(t)$ will be less than $5\eta^2$. That means we have

$$c_{t+2} < c_t(1 + (1 + \alpha(t))(1 - c_t) + 10\eta^2)^2(1 + 1 + \alpha(t+1))(1 - c_{t+1}) + 10\eta^2)^2$$
$$< c_t(1 + (1 + \alpha(t))(1 - c_t) + 10\eta^2)^2(1 + 1 + \alpha(t))(1 - c_{t+1}) + 15\eta^2)^2$$
$$< c_t(1 + (1 + \alpha(t))(1 - c_t))^2(1 + 1 + \alpha(t))(1 - c_{t+1})^2 + 100\eta^2$$
$$< c_t(1 + (1 + \alpha(t))(1 - c_t))^2(1 + 1 + \alpha(t))(1 - c_{t+1})^2 + 100\eta^2$$
$$< c_t(1 + (1 + \alpha(t))(1 - c_t))^2(1 + 1 + \alpha(t))(1 - c_{t+1})^2 + 200\eta^2$$

Similarly, we can have the lower bound of the 2-step dynamics.

$$c_{t+2} > c_t(1 + (1 + \alpha(t))(1 - c_t) - 2\eta^2)^2(1 + 1 + \alpha(t))(1 - c_{t+1}) - 2\eta^2)^2$$
$$> c_t(1 + (1 + \alpha(t))(1 - c_t) - 2\eta^2)^2(1 + 1 + \alpha(t))(1 - c_{t+1}) - 7\eta^2)^2$$
$$> c_t(1 + (1 + \alpha(t))(1 - c_t) - 2\eta^2)^2(1 + 1 + \alpha(t))(1 - c_{t+1})^2 - 100\eta^2$$
$$> c_t(1 + (1 + \alpha(t))(1 - c_t) - 2\eta^2)^2(1 + 1 + \alpha(t))(1 - c_{t+1})^2 - 200\eta^2$$

After bound all small terms to $200\eta^2$, we consider the main part

$$c_t(1 + (1 + \alpha(t))(1 - c_t))^2(1 + 1 + \alpha(t))(1 - c_{t+1})^2)^2$$

To prove it will decrease, we need to prove the factor

$$f(\alpha, c) = (1 + (1 + \alpha)(1 - c))(1 + 1 + \alpha)(1 - c(1 + 1 + \alpha)(1 - c))^2) < 1$$

when $\alpha \in (-\frac{1}{100}, \min\{\frac{1}{2}K^{-2}, 1/8\})$, $1 + K^{-1} - K^{-2} < c < 1.3$.

We first prove that the function $f(\alpha, c)$ monotonically increases when $\alpha > -\frac{1}{100}$ increases, i.e. $\frac{\partial f(\alpha, c)}{\partial \alpha} > 0$. We directly give the simplified expression of this partial derivative.

$$\frac{\partial f(\alpha, c)}{\partial \alpha} = (c - 1)(-4 - 2\alpha + c(1 + \alpha)(\frac{15}{16} + (2c(1 + \alpha) - \frac{17}{4} \alpha)^2))$$
$$= (c - 1)(-4 - 2\alpha + (1 + \alpha)(\frac{15}{16} c + (2c(1 + \alpha) - \frac{17}{4} \alpha)^2 c))$$
$$> (c - 1)(-2\alpha - 4 + (1 + \alpha)(\frac{15}{16} c + \frac{81}{4} (1 - \frac{1}{2} c)^2 c))$$

(since $-\frac{1}{100} < \alpha < 1/8$)

$$> (c - 1)(-2\alpha - 4 + (1 + \alpha) \times 4) \quad (c \in (1, \frac{13}{10}))$$

$$> 0.$$
Therefore, \( f(\alpha, c) < f(\frac{1}{2}K^{-2}, c) \) for all \( 1 + K^{-1} - K^{-2} < c < 1.3 \). Denote \( \beta = \frac{1}{2}(K^{-2} - 2K^{-3} + K^{-4}) \) and suppose \( c = 1 + t\sqrt{\beta} \) for some \( t > \sqrt{2} \) (since \( c > 1 + K^{-1} - K^{-2} \)). Meanwhile, since \( t\sqrt{\beta} < 0.3, t < 0.3\beta^{-1/2} \).

Then we plug in \( c = 1 + t\sqrt{\beta} \) and expand \( f(\beta, c) \).

\[
\begin{align*}
f(\beta, c) &= f(\beta, 1 + t\sqrt{\beta}) \[127] \\
&= 1 + 2t\beta^{3/2} - 2t\beta^{3/2} - 3t^2\beta^2 + t^4\beta^2 + 2t\beta^{5/2} - 5t^3\beta^{5/2} - 6t^2\beta^3 + 4t^4\beta^3 - 3t^3\beta^7/2 \\
&\quad - 3t^2\beta^4 + 6t^4\beta^4 + t^6\beta^6 + 4t^4\beta^5 + t^6\beta^{11/2} + t^4\beta^6 \\
&\leq 1 + (2t - t^3)\beta^{3/2} - 3t^2\beta^2 + 0.3t^3\beta^{3/2} + 2t\beta^{5/2} - 5t^3\beta^{5/2} - 6t^2\beta^3 + 1.2t^3\beta^{5/2} \\
&\quad - 3t^2\beta^4 - 3t^2\beta^4 + 1.8t^3\beta^7/2 + 0.3t^2\beta^4 + 0.36t^2\beta^4 + 0.3t^2\beta^5 + 0.09t^2\beta^5 \\
&\quad < 1 - 0.7t^3\beta^{3/2} - 3t^2\beta^2 < 1 - \beta^{3/2} - 6\beta^2
\end{align*}
\]

Thus we have

\[
c_{t+2} < c_t(1 - \beta^{3/2} - 6\beta^2)^2 + 200\eta^2 < c_t - \beta^{3/2} < c_t - \frac{1}{10}K^{-3}
\]

Thus it takes at most \( 2 \times 0.3/(\frac{1}{10}K^{-3}) < 6K \) steps for \( c_t \) to get into the region \( c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2}) \).

Finally we prove that if \( c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2}) \) for some \( s \), then for all \( t > s \),

\[
c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2}).
\]

We use induction and suppose \( c_t \) satisfies the condition above. Note that we have the upper and lower bound of \( c_{t+1} \) above:

\[
\begin{align*}
c_{t+1} &\leq c_t(1 + (1 + \alpha(t))(1 - c_t) + 10\eta^2)^2 \leq c_t(1 + (1 + \alpha(t))(1 - c_t))^2 + 100\eta^2 \\
c_{t+1} &\geq c_t(1 + (1 + \alpha(t))(1 - c_t) - 2\eta^2)^2 \geq c_t(1 + (1 + \alpha(t))(1 - c_t))^2 - 100\eta^2
\end{align*}
\]

Meanwhile \( c_t(1 + (1 + \alpha(t))(1 - c_t))^2 \) is monotonically decreasing with \( c_t \) when \( \frac{1}{100} < \alpha(t) < \frac{1}{2}K^{-2} \) and \( c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2}) \). Thus we have:

\[
\begin{align*}
c_{t+1} &\leq c_t(1 + (1 + \alpha(t))(1 - c_t))^2 + 100\eta^2 \\
&\leq (1 - K^{-1})(1 + K^{-1}(1 + \frac{1}{2}K^{-2}))^2 + 100\eta^2 \\
&= 1 + K^{-1} - K^{-2}(1 + \frac{1}{2}K^{-2})^2 + K^{-3} - K^{-3}(1 + \frac{1}{2}K^{-2})^2 + 100\eta^2 \\
&\quad < 1 + K^{-1} - K^{-2}.
\end{align*}
\]

\[
\begin{align*}
c_{t+1} &\geq c_t(1 + (1 + \alpha(t))(1 - c_t))^2 - 100\eta^2 \\
&> (1 + K^{-1} - K^{-2})(1 - (K^{-1} - K^{-2})(1 + \frac{1}{2}K^{-2}))^2 - 100\eta^2 \\
&= 1 - K^{-1} + 2K^{-3} - 3K^{-4} + 4K^{-5} - \frac{15}{4}K^{-6} + \frac{11}{4}K^{-7} - \frac{3}{2}K^{-8} \\
&\quad + \frac{3}{4}K^{-9} - \frac{1}{4}K^{-10} - 100\eta^2 \\
&\quad > 1 - K^{-1}.
\end{align*}
\]

Therefore, by induction we prove that for all \( t > s, c_t \in (1 - K^{-1}, 1 + K^{-1} - K^{-2}) \). In this way, \( \|x_t\|\|y_t\|-1 < K^{-1} \) for \( t > t_1 + T \).}

Entering the feasible region is not enough for establishing the equivalence to the scalar case. Furthermore, we need the alignment variable \( \xi_t \) to be small enough, such that some \( O(\cdot) \) notation term can contain all the terms with \( \xi \) in the \( (a, b) \)-parameterization dynamics.

However, we need to guarantee that the trajectory does not converge to an unstable point near the minima. We can prove that for the scalar case if the initialization is not exactly on the manifold of minimizers, but it becomes more challenging in higher dimensions. Therefore, we require an additional perturbation to escape from any unstable point. We pick the time \( t_p = T_0 + 6K^3 + 4K = O(-\log(\eta) + \log(d) - \log(\delta_0) + K^3) \) to guarantee that
when the perturbation happens, and they are aligned and \( (x^\top y)^2 \) is not large enough to cause instability. After the perturbation at \( t_p \), the gradient descent dynamics prevent the objective from hitting the manifold of minimizers.

The following lemma proves that the properties of the bound of \( c_t := (x^\top y)^2, \alpha = \eta ||x||^2 + ||y||^2 - 1 \) and \( \xi \) are still valid after the perturbation.

**Lemma 23.** After the perturbation at time \( t_p \), we have the following properties hold in \( t \in [t_p, 2t_p + 2] \): (i) After the perturbation \( c_{t_p} \in (1 + K^{-1} - 2K^{-2}, 1 + 3K^{-1} - 2K^{-2}) \), and \( c_t \in \big( \frac{7}{20}, \frac{13}{10} \big) \); (ii) \( \frac{K^2}{100} < \alpha(t) < \frac{1}{2} K^{-2} \); (iii) \( \xi_t < (0.7)^{t-t_p} \eta^2 \).

**Proof.** We prove this property by induction. Firstly, we prove the basis of induction at \( t = t_p \).

For (i), before perturbation we have \( c_{t_p} \in (1 - K^{-1}, 1 - K^{-1} - K^{-2}) \), so after the perturbation we have \( c_{t_p} \in (1 + K^{-1} - 2K^{-2}, 1 + 3K^{-1} + 2K^{-2}) \subset \big( \frac{7}{20}, \frac{13}{10} \big) \).

For (ii), the initial value of \( \alpha(t) \) satisfies that \( \frac{1}{100}K^{-2} < \alpha(0) < \frac{1}{2} K^{-2} \). But the total movement of \( \alpha(t) \) before perturbation is bounded \( -5\eta^2t_p, 5\eta^2t_p \subset \big( \frac{K^{-2}}{200}, \frac{K^{-2}}{200} \big) \), and the perturbation introduce a movement of \( ||y||^2 \) by \( ||y||^2 < \frac{10}{17} ||x||^2 < 1 + 3 \eta^2 \). Due to the upper bound of \( \eta, \alpha(t) \in \big( \frac{K^2}{100}, \frac{K^2}{2} \big) \).

For (iii), since \( K > 512 \), thus at \( t_p, \xi_{t_p} < (0.7)^{K^2} \eta^2 < (0.7)^6 K^2 \eta^2 \). After the perturbation \( \xi_{t_p} = 1 + 2K^{-1})^2 \xi_{t_p} < \eta^2 \). So all three statements hold for \( t = t_p \).

Then we suppose for \( t \in [t_p, t_p + t_1 + 1] \) all three statement holds and prove them for \( t_p + t_1 + 1 \). First by the dynamics of \( c_t \) with condition \( c_t \in \big( \frac{7}{20}, \frac{13}{10} \big) \) and \( 0 < \alpha(t) < \frac{K^2}{2} \), we have \( c_{t+1} < c_t(1 + (1 + \frac{K^2}{2})(1 - c_t))^2 \leq 13/10 \) and \( c_{t+1} > c_t(1 + (1 - c_t) - 10\eta^2)^2 > \frac{7}{20} \). Statement (i) is proved.

For (ii), since \( c_t \) and \( \xi_t \) are bounded for \( t \leq t_p + t_1 + 1 \), we can still have the total movement of \( \alpha(t) \) lies in \( (-5\eta^2t_p, 5\eta^2t_p) \subset \big( -\frac{K^{-2}}{200}, \frac{K^{-2}}{200} \big) \). Combine with the movement of \( y \) at perturbation \( (1 + (1 + \frac{K^2}{200})(1 - \eta^2)^2, \frac{K^2}{400} \), the total movement is still bounded by \( (-\frac{5\eta^2}{200}, \frac{5\eta^2}{200}) \), which proves the bound in (ii).

Finally for (iii), as long as \( c_t < \frac{13}{10} \), \( \xi_{t+1} < 0.7 \xi_t < 0.7^{t+1} \eta^2 \). Therefore all three statements are proved by induction.

After reclaiming all the bounds after the perturbation, we need to prove that the alignment variable \( \xi \) will be small enough to approximate the scalar case. The following lemma proves that \( b \) stays at a constant level when \( \alpha(t) \) is some constant.

**Lemma 24.** Suppose \( \xi_t < \eta^2, \eta < \frac{1}{20000}K^{-4}, \frac{K^2}{400} < \alpha(t) < \frac{1}{2} K^{-2} \) for all \( t \in [t_1, 2t_1 + 2] \) for some \( t_1 \). If \( (x_{t_i}^\top y_{t_i})^2 \in (1 + K^{-1} - 2K^{-2}, 1 + 3K^{-1} - 2K^{-2}) \), then for all \( t \in [t_1, 2t_1] \), \( (x_{t+i+2k}^\top y_{t+i+2k})^2 \in (1 + \frac{1}{20}K^{-1}, 1 + 3K^{-1} - 2K^{-2}) \), \( (x_{t+i+2k}^\top y_{t+i+2k})^2 \) is the lower bound of \( (x_{t+i+2k}^\top y_{t+i+2k})^2 \). We prove the sequence of the \( c_{t+i} = 0, 1, \ldots \) by induction, and then use this conclusion to prove the upper bound of \( c_{t+i} = 0 \). We know that \( k = 0 \) the statement holds. Then suppose the lower bound holds for \( k \leq k_0 \), and we prove it for \( k = k_0 + 1 \).

Here we consider the function as we do in Lemma 22:

\[
 f(\alpha, c) = (1 + (1 + \alpha)(1 - c))(1 + (1 + \alpha)(1 - c)(1 + (1 + \alpha)(1 - c))^2) \)
\[
 f(\alpha, c) > f(\gamma, c)
\]

Suppose \( c_{t+i+2k} = 1 + q\sqrt{\gamma}, q \in (1/2, 30 + 40K^{-1}) \). Then the expression \( f(\gamma, c) \) becomes:

\[
 f(\gamma, c) = f(\gamma, 1 + q\sqrt{\gamma}) = 1 + 2q\gamma^{3/2} - 2q^3\gamma^{3/2} - 3q^2\gamma^2 + q^4\gamma^2 + 2q\gamma^{5/2} - 5q^2\gamma^{5/2} - 6q^2\gamma^3 + 4q^4\gamma^2 - 3q^3\gamma^{7/2}
\]
\[ -3q^2 \gamma^4 + 6q^4 \gamma^4 + q^3 \gamma^{9/2} + 4q^4 \gamma^5 + q^3 \gamma^{11/2} + q^4 \gamma^6 \]

Notice that when \( c > 1 \), \( f(\gamma, c) \) decrease as \( c \) increase. Now we consider the range of \( q \): If \( q \in \left( \frac{1}{2}, \frac{2}{3} \right] \), we have:

\[
\begin{align*}
f(\gamma, c) &\geq f(\gamma, 1 + \frac{2}{3} \sqrt{7}) \\
&= \frac{20 \gamma^{3/2}}{27} - \frac{4 \gamma^{5/2}}{27} - \frac{8 \gamma^{7/2}}{27} + \frac{8 \gamma^{9/2}}{27} + \frac{8 \gamma^{11/2}}{27} \\
&\quad + \frac{16 \gamma^6}{81} - \frac{64 \gamma^4}{81} - \frac{152 \gamma^3}{81} + \frac{92 \gamma^2}{81} + 1 \\
&> 1 + \frac{10}{27} \gamma^{3/2}. \quad (\text{since } K > 512, \gamma^{1/2} = \frac{K^{-1}}{10})
\end{align*}
\]

That means \( c_{t_1+2k+2} > ((1 + \frac{10}{27} K^{-2}) - 200 \eta^2)c_{t_1+2k} > c_{t_1+2k} > (1 + \frac{1}{20 K^{-1}}) \) and the proof is done. Otherwise, we have \( q \in \left( \frac{2}{3}, 30 + 40K^{-1} \right), \) also we have the lower bound of this function:

\[
\begin{align*}
f(\gamma, c) &\geq f(\gamma, 1 + \frac{2}{3} \sqrt{7}) \\
&= -127920\gamma^{3/2} - 319920\gamma^{5/2} - 192000\gamma^{7/2} + 64000\gamma^{9/2} + 64000\gamma^{11/2} \\
&\quad + 2560000\gamma^6 + 1024000\gamma^4 + 15355200\gamma^3 + 10230400\gamma^2 + 2555200\gamma^2 + 1 \\
&> 1 - 100000\gamma^{3/2}. \quad (\text{since } K > 512, \gamma^{1/2} = \frac{K^{-1}}{10})
\end{align*}
\]

That means

\[
c_{t_1+2k+2} > ((1 - 100000\gamma^{3/2}) - 200 \eta^2)c_{t_1+2k} \\
> (1 - 200000\gamma^{3/2} - 200 \eta^2)(1 + \frac{2}{3} \sqrt{7}) \\
> (1 - \frac{200000}{26214400} \gamma^{3/2} - 200 \eta^2)(1 + \frac{2}{3} \sqrt{7}) \\
> (1 - \frac{1}{1000} K^{-1} - \frac{1}{4000} K^{-4})(1 + \frac{K^{-1}}{15}) \\
> (1 + \frac{1}{20} K^{-1})
\]

Then the lower bound of \( c_{t_1+2k} \) is proved.

As for the upper bound, since when \( t = t_1 + 2k, x, y \) satisfies all the conditions in Lemma 22. If \( c_{t_1+2k} < 1 + K^{-1} - K^{-2} \), we have proved that it will never be larger than \( 1 + K^{-1} - K^{-2} \). Otherwise if \( c_{t_1+2k} \in (1 + K^{-1} - K^{-2}, 1 + 3K^{-1} + 2K^{-2}) \) we apply the inequality Eq. (127) and know \( c_{t_1+2k+2} < c_{t_1+2k}. \) In this way, by induction we prove the bound \( (x_{t_1+2k}^{-}, y_{t_1+2k+2})^2 \in (1 + \frac{1}{20} K^{-1}, 1 + 3K^{-1} + 2K^{-2}) \)

As for the upper bound of \( (x_{t_1+2k-1}^{-}, y_{t_1+2k-1})^2 \), we directly apply the upper bound of 1-step dynamics (if \( c_t > 1 + \frac{1}{20} K^{-1} \)):

\[
c_{t+1} \leq c_t (1 + (1 + \alpha(t))(1 - c_t) + 10 \eta^2)^2 \\
< c_t (2 - c_t + 10 \eta^2)^2 \\
< (1 + \frac{K^{-1}}{20})(1 - \frac{K^{-1}}{20})^2 + 10 \eta^2 \\
< 1 - \frac{K^{-1}}{20} K^{-2} + \frac{1}{8000} K^{-3} + 10 \eta^2 \\
< 1 - \frac{1}{20} K^{-1}
\]

Therefore the upper bound \( (x_{t_1+2k-1}^{-}, y_{t_1+2k-1})^2 \) \( < 1 - \frac{1}{20} K^{-1} \) holds for all \( k < t_1/2 \).

\[\blacksquare\]

Finally, we denote \( \alpha := \sqrt{\|x\|^2 - \|y\|^2} - (\eta^{-2} - 4)^{1/2}, b := \|x\| \|y\| - 1 \). With all the lemmas above, we prove the equivalence between the dynamics of \((a, b)\) and the one step dynamics of in the scalar case (Lemma 1, Lemma 2).
For simplicity of notations, when analyzing the 1-step and 2-step dynamics of \((a_t, b_t)\), we use \(a, a'\) to denote \(a_t, a_{t+1}\) and \(b, b'\) to denote \(b_t, b_{t+1}\), etc. For simplicity of calculation, we consider the change of variable \(\kappa = \sqrt{\eta}\).

**Lemma 25. (Equivalence with scalar updates)** If \(\xi_t < \min\{\eta^2, \eta b_t^4\}\), \(\|x_t\| \in (\bar{x} + \frac{1}{2\eta} K^{-2}\eta^{-\frac{1}{2}}, \bar{x} + \frac{1}{4} K^{-2}\eta^{-\frac{1}{2}} + K^{-1})\) and \(||x_t|| ||y_t|| - 1 < K^{-1}\), the following equations hold for some fixed constant \(\epsilon = \min\{0.5, \frac{1}{128} K^{-1}\}\):

\[
a' = a - 2b\kappa^2 + O(b^2\kappa^4) + O(b^2\kappa^4) + O(b^2\kappa^4) + O(b^2\kappa^4) + O(b^2\kappa^4).
\]

\[
b' = -b - 4ab\kappa - 3b^2 - b^3 + O(ab^2\kappa) + O(a^2\kappa^2) + O(b^2\kappa^4) + O(b^2\kappa^4) + O(b^2\kappa^4).
\]

**Proof.** For simplicity, we denote \(x = \|x\|\) and \(y = \|y\|\). We first prove that:

\[
x' = x + \kappa^2 xy^2(1 - x^2 y^2) + O(\kappa^4 b^2).
\]

\[
y' = y + \kappa^2 x^2 y(1 - x^2 y^2) + O(\kappa^2 b^2).
\]

We suppose \(y = cx + \theta\) for some \(\theta \in \mathbb{R}^d\) and \(\theta, x = 0\). In this way, we have \(x^T y = cx^2, y^2 = c^2 x^2 + \|\theta\|^2, \xi = x^2 \|\theta\|^2\). Since \(x < \eta b^4\) and \(x = O(\kappa^{-1})\), \(\|\theta\| = O(\kappa^2 b^2)\).

Then check the dynamics of \(x\) and plug in \(y = cx + \theta\):

\[
x' = x + \eta((x^T y)y - \frac{1}{2}(x^T y)(x^T y) - \frac{1}{2}(x^T y)^2) x
\]

\[
(1 + \eta y^2 - \eta x^2 y^2) x + (-\eta \|\theta\|^2 + \eta x^2 y^2) x + (\eta(x^T y) - \frac{1}{2} \eta(x^T y)(x^T y)^2) \theta.
\]

Since \((x^T y)\) and \(x y\) are both bounded as constant, we can directly take the norm of both sides and with triangle inequality we have:

\[
x' = x + \kappa^2 xy^2(1 - x^2 y^2) + O(\kappa^4 b^2).
\]

Similarly, we have the dynamics of \(y\):

\[
y' = y + \kappa^2 x^2 y(1 - x^2 y^2) + O(\kappa^2 b^2).
\]

We now reparameterize the dynamics in \((a, b)\)-parameterization.

\[
a' = a + (\kappa^{-4} - 4) \frac{1}{2} (1 - b^2(1 + b^2)(2 + b^2)\kappa^4) - (\kappa^{-4} - 4) \frac{1}{2} + O(b^2\kappa^4).
\]

\[
b' = b - 2b\delta - 3b^2\delta - b^3\delta + 4b^3\kappa^4 + 16b^3\kappa^4 + 25b^4\kappa^4 + 19b^4\kappa^4 + 7b^4\kappa^4 + b^7\kappa^4 + O(ab^2\kappa^2)
\]

where \(\delta = \sqrt{4\eta^2(1 + b^2) + (\alpha^2\kappa^2 + (1 - 4\eta^2)\kappa^4)}\).

And by the bound of \(||x_t||\) and \(||x_t|| ||y_t|| - 1\), we can have \(|a| < \epsilon \kappa, |b| < \min\{1, 4\kappa^{-2}\}\), which satisfies the condition in Lemma 1 and Lemma 2. Then we follow the proof of Lemma 1 and Lemma 2 to finish the proof (since the only difference is the two \(O(\cdot)\) notation).

After we can reduce the dynamics of vector case to the scalar case dynamics, we need to prove that in the scalar case (in all stages), for any \(t \geq 0\), \((\frac{b_t+1}{b_t})^4 > 0.7\), which means \(\xi_t\) shrinks faster than \(b_t^4\). In that case, we can conclude that \(\xi_t > \eta b_t^4\) always holds along the scalar case trajectory.

**Lemma 26.** Suppose all conditions in Theorem 3.1 hold. Then for all \(t > 0\), \((\frac{b_t+1}{b_t})^4 > 0.7\).

**Proof.** From the proof of Theorem 3.1, we know that for all \(t > 0\), \(|b_t| < K^{-1}\) and \(|a_t| < \kappa^{-1}\). Thus Lemma 2 holds and for all \(t \geq 0\) we have:

\[
b_{t+1} = -b_t - 4a_tb_t\kappa - 3b_t^2 - b_t^3 + O(a_t b_t^2\kappa) + O(a_t^2 b_t^2\kappa) + O(b_t^2\kappa^4) + O(b_t^2\kappa^4).
\]

Since we know all constants hidden by the \(O(\cdot)\) operator are upper bounded by \(K\), we have the following lower bound on the multiplicative update of \(b\):

\[
\frac{b_{t+1}^4}{b_t^4} \geq (1 - 4a_t\kappa - 3b_t - b_t^2 - K + a_t b_t^2\kappa - K a_t^2 b_t^2\kappa - K b_t^2\kappa^4 - K b_t^2\kappa^4 - K b_t^2\kappa^4)
\]

\[
\geq (1 - 4K^{1/2} - 3K^{-1} - K^{-2} - K^{-2} - 4 - 4 - 4 - 4)\]

\[
\geq (1 - 10K^{-1})^4 > \left( \frac{502}{512} \right)^4 > 0.7.
\]

\[\square\]
Finally we conclude the proof of Theorem C.1.

**Proof of Theorem C.1.** By Lemma 21, we know with probability $1 - 2\delta_0 - 2\exp\{-\Omega(d)\}$, there exists some time $T_0 = \mathcal{O}(-\log(\eta) - \log(\delta_0) + \log(d))$ that $\xi_t < \eta^2$ for all $t > T_0$. Also for $t \in [T_0, T_0 + 6K^3 + 4K]$, $\|x_t\| \in (\tilde{x} + \frac{1}{2\delta_0}K^{-2}\eta^{-\frac{1}{2}}, \tilde{x} + \frac{1}{\delta_0}K^{-2}\eta^{-\frac{1}{2}})$. This bound of $\|x\|$ guarantees that for $t \in [T_0, T_0 + 6K^3 + 4K]$, $\alpha(t) \in (0, \frac{K-2}{200})$, which satisfies the condition of Lemma 22.

Then by Lemma 22, we know for some $t^* < T_0 + 6K^3 + 4K < t_p$, $\|\|x_t\||\|y_t\| - 1\| < K^{-1}$ for $t \in [t^*, t_p]$. After entering and staying in the region, we add the perturbation at $t_p$. By Lemma 23, we have the bounds before perturbation still hold: (i) After the perturbation $c'_{t_p} \in (1 + K^{-1} - 2K^{-2}, 1 + 3K^{-1} + 2K^{-2})$, and $c_t \in (\frac{7}{20}, \frac{11}{10})$; (ii) $\frac{K-2}{200} < \alpha(t) < \frac{1}{2}K^{-2}$; (iii) $\xi_t < (0.7)^{t-t_p}\eta^2$. Therefore, the condition of Lemma 22 and Lemma 24 are both met. So after another $6K^3 + 4K$ steps, we have $|b_t| = ||x_t|| ||y_t|| - 1 < K^{-1}$ and $|(x_t^\top y_t)^2 - 1| > 1 - \frac{K^{-1}}{20}$. The second expression can lead to $|b_t| > \frac{K^{-1}}{20} / (1 + \|x_t\| ||y_t||) > \frac{K^{-1}}{41}$. This means $\xi_t < (0.7)^{4K}\eta^2 < (0.7)^{2000}\eta^4 \cdot \frac{K^{-3}}{80000} < \eta |b_t|^4$.

By Lemma 25, we know the dynamics of the norm of the vectors $(\|x\|, \|y\|)$ can be captured by the scalar case (including the initialization condition and the one step update rules). And by Lemma 26, we know the alignment will be kept and the dynamics of the vectors will always be true.

Finally, we apply Theorem 3.1 and finish the proof. \qed
