Abstract. A geometric approach to general quantum statistical systems (including the harmonic oscillator) is presented. It is applied to Casimir energy and the dissipative system with friction. We regard the (N+1)-dimensional Euclidean coordinate system (X', \tau) as the quantum statistical system of N quantum (statistical) variables (X') and one Euclidean time variable (\tau). Introducing paths (lines or hypersurfaces) in this space (X', \tau), we adopt the path-integral method to quantize the mechanical system. This is a new view of (statistical) quantization of the mechanical system. The system Hamiltonian appears as the area. We show quantization is realized by the minimal area principle in the present geometric approach. When we take a line as the path, the path-integral expressions of the free energy are shown to be the ordinary ones (such as N harmonic oscillators) or their simple variation. When we take a hyper-surface as the path, the system Hamiltonian is given by the area of the hyper-surface which is defined as a closed-string configuration in the bulk space. In this case, the system becomes a O(N) non-linear model. We show the recently-proposed 5 dimensional Casimir energy (ArXiv:0801.3064,0812.1263) is valid. We apply this approach to the visco-elastic system, and present a new method using the path-integral for the calculation of the dissipative properties.

1. Introduction
In the quest for the fundamental structure of the space, time, and matter, the most advanced theories are the string theory, D-brane theory and M-theory[1]. They are beyond the quantum field theory in that the extended (in space-time) objects are treated as fundamental elements. Since the finding of AdS/CFT correspondence[2, 3, 4], various new ideas and techniques, developed for them, are imported into the non-perturbative analysis of the quantum field theories. In particular, the application to the material physics is marvelous: heavy ion collision physics and the viscosity in the quark-gluon plasma([5, 6, 7] for review), superconductivity and superfluidity [8, 9, 10, 11], baryon mass spectrum in QCD[12, 13]. In this circumstance, a new standpoint about the space-time quantization appear. One is proposed by Hořava[14, 15]. He introduced Lifshitz’s higher-derivative scalar theory and its renormalization group behavior into his idea about the new quantum gravity. Another one is revively given by E. Verlinde[16]. He emphasizes the entropic force (rather than energetic force) and the thermodynamical behavior near the horizon (Hawking radiation). With this recent trend of the geometrical view, the statistical(thermal) view and the visco-elastic view , we present a new formalism where the quantum statistical system is treated purely in the geometrical way.
In the analysis of the dissipative material-system, due to friction, one familiar way is to treat it as the hydrodynamic system of a continuum medium. The incompressible viscous flow (Newton’s flow is assumed) is described by Navier-Stokes equation.

\[
\frac{Dv_i}{Dt} \equiv (\frac{\partial}{\partial t} + v^j \frac{\partial}{\partial x_j}) v^i = -\frac{1}{\rho} \partial_i P + \frac{\eta}{\rho} \Delta v^i + g^i ,
\]

\[i, j = 1, 2, 3 \quad , \quad \vec{x} \equiv (x^1, x^2, x^3) = (x, y, z) \quad , \quad \partial_i \equiv \frac{\partial}{\partial x^i} \quad , \quad \Delta \equiv \partial_1^2 + \partial_2^2 + \partial_3^2 \quad , \]

\[v^i = v^i(t, \vec{x}) \quad , \quad P = P(t, \vec{x}) \quad , \quad (1)\]

where \(\vec{g} \equiv (0, 0, g)\) is the gravitational acceleration constant. \(\rho\) and \(\eta\) is the mass density (constant) and the viscosity (constant) of the fluid, respectively. \(\vec{v} \equiv (v^1, v^2, v^3)\) is the velocity field and \(P(t, \vec{x})\) is the pressure field. This equation has been examined analytically and numerically in various ways. The statistical quantities of the system has been obtained, for example, by introducing the random force (Langevin equation, the stochastic method, Fokker-Planck equation). In the present work, by introducing a metric in \((t, x^i)\)-space, we treat this system geometrically. The statistical or global quantities (energy, entropy, etc.) are expressed in the path-integral form.

As another application, we take Casimir energy. It is the vacuum (zero temperature) energy for the free (non-interacting) part of the quantum system. It is a basic quantity of the quantum field theory (QFT) such as the field of radiation (the electromagnetic field). Generally it is expressed by the boundary parameters of the system. The quantity is so delicately defined that we need careful regularization of divergences. The present approach gives a new regularization which has some characteristic points compared with the ordinary one. Especially the direction of the renormalization group flow determines the attractiveness or repulsiveness. We also apply the present approach to 5 dimensional (dim) field theories (flat and curved ones), and well-define the higher-dimensional QFTs.

The content is organized as follows. We start with the simple quantum statistical system of one harmonic oscillator in Sec.2. We see the geometric approach works well by regarding the extra coordinate as the Euclidean time. We generalize the harmonic oscillator potential (elastic system) to the general one in Sec.3. In Sec.4 the one variable system is generalized to the system of \(N\) variables. We analyze the quantum statistical system in the \(N+1\) extra dimensional Euclidean geometry. The O(\(N\)) nonlinear model naturally appears by taking the closed-string configuration. We stress that taking the area as Hamiltonian is one realization of the minimal area principle. In Sec.5, we apply the present approach to Casimir energy. The visco-elastic system is treated in Sec.6. We conclude in Sec.7. In Appendix A, some detail of Sec.5.2 (Casimir energy in 5D curved space) is explained.

2. Quantum Statistical System of Harmonic Oscillator

2.1. ‘Dirac’ Type

Let us consider 2 dim Euclidean space \((X, \tau)\) described by the following metric.

\[
ds^2 = dX^2 + \omega^2 X^2 d\tau^2 = G_{AB} dX^A dX^B \quad ,
\]

\[\left( X^A \right) = (X^1, X^2) = (X, \tau) \quad , \quad (G_{AB}) = \text{diag}(1, \omega^2 X^2) \quad , \quad R_{AB} = 0 \quad , \quad R = G^{AB} R_{AB} = 0 \quad , \quad (2)
\]

where \(A, B = 1, 2\). The parameter \(\omega\) is the ‘spring’ constant with the dimension of mass. We impose the periodicity (period: \(\beta\)) in the direction of the extra dimension \(\tau\).

\[\tau \rightarrow \tau + \beta \quad . \quad (3)\]
This is a way to introduce the temperature \((1/\beta)\) in the system. Here we take a path \(\{x(\tau), \ 0 \leq \tau \leq \beta\}\) in the 2D bulk space \((X, \tau)\) and the induced metric on the line is given by

\[
X = x(\tau) \ , \ dX = \dot{x} d\tau \ , \ \dot{x} \equiv \frac{dx}{d\tau} \ , \ 0 \leq \tau \leq \beta \ , \\
\text{ds}^2 = (\dot{x}^2 + \omega^2 x^2) d\tau^2 .
\] (4)

See Fig.1.

Then the length \(L\) of the path \(x(\tau)\) is given by

\[
L = \int ds = \int_{0}^{\beta} \sqrt{\dot{x}^2 + \omega^2 x^2} d\tau .
\] (5)

We take the half of the length \((\frac{1}{2}L)\) as the system Hamiltonian (minimal length principle). Then the free energy \(F\) of the system is given by

\[
e^{-\beta F} = \int_{-\infty}^{\infty} dp \int \frac{x(0) = \rho}{x(\beta) = \rho} \prod_{\tau} Dx(\tau) \exp \left[ -\frac{1}{2} \int_{0}^{\beta} \sqrt{\dot{x}^2 + \omega^2 x^2} d\tau \right] ,
\] (6)

where the path-integral is done for all possible paths with the indicated boundary condition (b.c.). This quantum statistical system can be regarded as the square-root type (Dirac type) of the ordinary harmonic oscillator.  

2.2. Standard Type

Now we consider another type of 2 dim Euclidean space \((X, \tau)\) described by the following line element.

\[
ds^2 = \frac{1}{d\tau^2} (dX^2)^2 + \omega^4 X^4 d\tau^2 + 2\omega^2 X^2 dX^2 = \frac{1}{d\tau^2} (dX^2 + \omega^2 X^2 d\tau^2)^2 ,
\] (7)

1 The situation reminds us of the relation between Nambu-Goto action and Polyakov action in the string theory[17]. The introduction of an auxiliary variable helps to 'normalize' the square-root action (6). In this case, the geometric role of the auxiliary variable remains obscure.
where we put the following condition on the infinitesimal quantities, $d\tau^2$ and $dX^2$, in order to keep all terms of (7) in the same order.

\[
\text{[Line Element Regularity Condition]} : \quad d\tau^2 \sim O(\epsilon^2) , \quad dX^2 \sim O(\epsilon^2) , \quad \frac{1}{d\tau^2} dX^2 \sim O(1) ,
\]

(8)

where $\epsilon$ is an arbitrary infinitesimal parameter with the dimension of length. Note that we do not have 2D metric in this case. (We cannot define the bulk metric $G_{AB}(X)$.) We impose the periodicity (period: $\beta$).

\[
\tau \to \tau + \beta .
\]

(9)

Here we take a path \( \{x(\tau), \; 0 \leq \tau \leq \beta\} \), and the induced metric on the line is given by

\[
X = x(\tau) , \quad dX = \dot{x} d\tau , \quad \dot{x} \equiv \frac{dx}{d\tau} , \quad 0 \leq \tau \leq \beta ,
\]

\[
ds^2 = (\dot{x}^2 + \omega^2x^2)^2d\tau^2 .
\]

(10)

In the bulk we do not have the metric, but on the path, we do have this induced metric. Then the length $L$ of the path $x(\tau)$ is given by

\[
L[x(\tau)] = \int ds = \int_0^\beta (\dot{x}^2 + \omega^2x^2)d\tau .
\]

(11)

\[ \text{2 The condition (8) restricts the trajectory configuration (10) only to smooth-lines in the 2D bulk space, and excludes singular-lines which have some singular points (the derivative along } \tau \text{ can not be defined) between } 0 \leq \tau \leq \beta. \text{ See Fig.2 for singular and regular lines.} \]
Hence, taking \( \frac{1}{2}L \) as the Hamiltonian (minimal length principle), the free energy \( F \) of the system is given by

\[
e^{-\beta F} = \int_{-\infty}^{\infty} dp \int_{x(0)=\rho}^{x(\beta)=\rho} \prod_{\tau} Dx(\tau) \exp \left[ -\frac{1}{2} \int_0^\beta (\dot{x}^2 + \omega^2 x^2) d\tau \right] , \tag{12}
\]

where the path-integral is done for all possible paths with the indicated b.c. This is exactly the free energy of the harmonic oscillator. See Feynman's textbook\[18].

Note that the condition (8) is necessary for the elastic view to the path.

### 3. General Quantum Statistical System

We generalize the harmonic oscillator potential, \( \frac{1}{2} \omega^2 X^2 \), to the general one \( V(X) \). As for \( V(X) \), we have the following form in mind.

\[
\frac{\omega^2}{2} X^2 + \frac{\lambda_3}{3!} X^3 + \frac{\lambda_4}{4!} X^4 + \cdots , \tag{13}
\]

where \( \lambda_3, \lambda_4, \cdots \) are the coupling constants for additional terms.

#### 3.1. 'Dirac' Type

We start with the following metric in 2 dim Euclidean space \((X, \tau)\).

\[
ds^2 = dX^2 + 2V(X)d\tau^2 = G_{AB} dX^A dX^B , \quad (X^A) = (X^1, X^2) = (X, \tau) , \quad (G_{AB}) = \text{diag}(1, 2V(X)) ,
\]

\[
(R_{AB}) = \begin{pmatrix} V'' - \frac{1}{2} \left( \frac{V'}{V} \right)^2 & 0 \\ 0 & \frac{1}{2} \left( \frac{V'}{V} \right)^2 \end{pmatrix} , \quad R = G^{AB} R_{AB} = \frac{V''}{V} - \frac{1}{2} \left( \frac{V'}{V} \right)^2 ,
\]

\[
V' = \frac{dV(X)}{dX} , \quad V'' = \frac{d^2V(X)}{dX^2} . \tag{14}
\]

where \( A, B = 1, 2 \). Note that \( V(X) \) does not depend on \( \tau \). We impose the periodicity (period: \( \beta \)) in the direction of the extra dimension \( \tau \) \((3)\). On a path \( \{x(\tau), 0 \leq \tau \leq \beta\} \), the induced metric is given by

\[
ds^2 = (\dot{x}^2 + 2V(x)) d\tau^2 , \quad 0 \leq \tau \leq \beta . \tag{15}
\]

Hence the length \( L \) of the path \( x(\tau) \) is given by

\[
L = \int ds = \int_0^\beta \sqrt{\dot{x}^2 + 2V(x)} d\tau . \tag{16}
\]

Taking the half of the length \( \left( \frac{1}{2}L \right) \) as the Hamiltonian, we get the free energy \( F \) as

\[
e^{-\beta F} = \int_{-\infty}^{\infty} dp \int_{x(0)=\rho}^{x(\beta)=\rho} \prod_{\tau} Dx(\tau) \exp \left[ -\frac{1}{2} \int_0^\beta \sqrt{\dot{x}^2 + 2V(x)} d\tau \right] . \tag{17}
\]

\[3 \quad F = \frac{E}{T} + \frac{1}{T} \ln(1 - e^{-\beta \omega}) , \quad E = \langle \frac{1}{2} \dot{q}^2 \rangle = \frac{1}{\hbar} \coth \left( \frac{\hbar \omega}{2T} \right) = \frac{1}{\hbar} + \frac{\hbar \omega}{e^{\hbar \omega/T} - 1} , \quad S = \frac{1}{T} (E - F) = k \left( \frac{\hbar \omega}{T} \coth \left( \frac{\hbar \omega}{2T} \right) - \frac{\hbar \omega}{T} - \ln(1 - e^{-\beta \omega}) \right) \]
3.2. Standard Type
We start with the following line element.
\[ ds^2 = \frac{1}{d\tau^2} (dX^2)^2 + 4V(X)^2 d\tau^2 + 4V(X)dX^2 = \frac{1}{d\tau^2} \left( dX^2 + 2V(X)d\tau^2 \right)^2, \]
where we put the condition (8) on the infinitesimal quantities, \( d\tau^2 \) and \( dX^2 \), in order to keep all terms in the same order. The 2D bulk space do not have 2D metric. We impose the periodicity (period: \( \beta \)) (9). On a path \( \{x(\tau), 0 \leq \tau \leq \beta\} \), we have the induced metric:
\[ ds^2 = (\dot{x}^2 + 2V(x))^2 d\tau^2. \]
The length \( L \) is given by
\[ L[x(\tau)] = \int ds = \int_0^\beta (\dot{x}^2 + 2V(x))d\tau. \]
Taking \( \frac{1}{2}L \) as the Hamiltonian, the free energy \( F \) is given by
\[ e^{-\beta F} = \int_{-\infty}^{\infty} dp \int x(0) = \rho \prod_{x(\beta) = \rho} \int \mathcal{D}x(\tau) \exp \left[ -\frac{1}{2} \int_0^\beta (\dot{x}^2 + 2V(x))d\tau \right], \]
where the path-integral is done for all possible paths with the indicated b.c.. This is exactly the free energy of the quantum statistical system of one variable \( x \) in the general potential \( V(x) \).

4. Quantum Statistical System of N Harmonic Oscillators and O(N) Nonlinear Model

4.1. 'Dirac' Type of N Harmonic Oscillators and O(N) nonlinear system

Let us consider \( N+1 \) dim Euclidean space \( (X^i, \tau), i = 1, 2, \cdots, N \) described by the following metric.
\[ ds^2 = \sum_{i=1}^{N} (dX^i)^2 + \omega^2 d\tau^2 \sum_{i=1}^{N} (X^i)^2 = \sum_{i=1}^{N} (dX^i)^2 + \omega^2 r^2 d\tau^2 = G_{AB} dX^A dX^B, \]
\[ A, B = 1, 2, \cdots, N, N + 1; \quad X^{N+1} = \tau, \]
\[ (G_{AB}) = \text{diag}(1, 1, \cdots, 1, \omega^2 r^2), \quad r^2 \equiv \sum_{i=1}^{N} (X^i)^2. \]
(Subsec.2.1 is the $N=1$ case.) The Ricci tensor and the scalar curvature are, for $N=2$, given by

$$ (R_{AB}) = \frac{1}{(r^2)^2} \begin{pmatrix} y^2 & -xy & 0 \\ -yx & x^2 & 0 \\ 0 & 0 & \omega^2(r^2)^2 \end{pmatrix} , \quad R = \frac{2}{r^2} > 0 , \quad r^2 = x^2 + y^2 , $$

$$ \sqrt{G} = \omega \sqrt{x^2 + y^2} , \quad \sqrt{G}R = \frac{2\omega}{\sqrt{x^2 + y^2}} . \quad (23) $$

where $(X^1, X^2, X^3) = (x, y, \tau)$ is taken.

We impose the periodicity (3) (period: $\beta$), and take a path $\{X^i = x^i(\tau) | 0 \leq \tau \leq \beta, \ i = 1, 2, \cdots, N\}$ (See Fig.3). The induced metric on the line is given by

$$ X^i = x^i(\tau) , \quad dX^i = \dot{x}^i d\tau , \quad \dot{x}^i \equiv \frac{dx^i}{d\tau} , \quad 0 \leq \tau \leq \beta , $$

$$ i = 1, 2, \cdots, N \quad ds^2 = \sum_{i=1}^{N}((\dot{x}^i)^2 + \omega^2(x^i)^2)d\tau^2 . \quad (24) $$

Then the length $L$ of the path $\{x^i(\tau)\}$ is given by

$$ L = \int ds = \int_{0}^{\beta} \sqrt{\sum_{i=1}^{N}((\dot{x}^i)^2 + \omega^2(x^i)^2)} d\tau . \quad (25) $$

We take the half of the length ($\frac{1}{2}L$) as the system Hamiltonian (minimal length principle). Then the free energy $F$ of the system is given by

$$ e^{-\beta F} = (\prod_{i} \int_{-\infty}^{\infty} d\rho_i) \int x^i(0) = \rho_i \prod_{\tau,i} Dx^i(\tau) \exp \left[ -\frac{1}{2} \int_{0}^{\beta} \sqrt{\sum_{i=1}^{N}((\dot{x}^i)^2 + \omega^2(x^i)^2)} d\tau \right] , \quad (26) $$

where the path-integral is done for all possible paths $\{x^i(\tau); i = 1, 2, \cdots N\}$ with the indicated b.c. We can regard this as the free energy for a variation (Dirac type) of the N harmonic oscillators's. (See next subsection for the ordinary type of the N harmonic oscillators.)

Instead of the length $L$, we can take another geometric quantity. Let us consider the following $N$ dim hypersurface in $N+1$ dim space (a closed-string configuration). See Fig.4 for the $N=2$ case.

$$ \sum_{i=1}^{N} (X^i)^2 = r^2(\tau) , \quad \sum_{i=1}^{N} X^i dX^i = r d\tau , \quad 0 \leq \tau \leq \beta . \quad (27) $$

The form of $r(\tau)$ describes a path (N dimensional hypersurface in the bulk) which is isotropic in the 'brane' at $\tau$ (the N dim space 'perpendicularly' standing at $\tau$ of the extra axis, not the hypersurface). The induced metric on the N dim hypersurface is given by

$$ ds^2 = \sum_{i,j} (\delta_{ij} + \frac{\omega^2}{r^2} x^i x^j) dx^i dx^j \equiv \sum_{i,j} g_{ij} dx^i dx^j , $$

$$ g_{ij} = \delta_{ij} + \frac{\omega^2}{r^2} x^i x^j , \quad r^2 = \sum_{i=1}^{N} (x^i)^2 , \quad \det(g_{ij}) = 1 + \frac{\omega^2 r^2}{r^2} . \quad (28) $$

4 All curvature calculation in this work is checked by the algebraic calculation soft "Maxima"[19].
Figure 4. A path of hyper-surface.
N(-2) dim hypersurface in N+1 dim space \((X^1, X^2, \ldots, X^N, \tau)\).
\(S^{N-1}\) radius \(r(\tau)\) starts with \(r(0) = \rho\) and ends with \(r(\beta) = \rho'\).
We take this configuration as a path in the path integral (30) and (41). This is a closed-string configuration.

This is the metric of a \(O(N)\) nonlinear system and is the one dimensional \(nonlinear\ sigma model\) as the field theory. (The standard model (2 dim nonlinear sigma model) has often been used so far in order to show the \(renormalization\ group\) behavior of various systems. The background (effective action) formulation of the string theory heavily relies on the model.) Then the \(area\) of the \(N\) dim hypersurface is given by

\[
A_N = \int \sqrt{\det g_{ij}} \, d^N x = \frac{N \pi^{N/2}}{\Gamma(N/2 + 1)} \int \sqrt{\tau^2 + \omega^2 r^2 r^{N-1}} \, d\tau .
\] (29)

When we take \(\frac{1}{2}A_N\) as the Hamiltonian (\(minimal\ area\ principle\)), the free energy \(F\) is given by

\[
e^{-\beta F} = \int_0^\infty d\rho \int r(0) = \rho \prod_{r(\beta) = \rho} \exp \left[ -\frac{1}{2} \frac{N \pi^{N/2}}{\Gamma(N/2 + 1)} \int \sqrt{\tau^2 + \omega^2 r^2 r^{N-1}} \, d\tau \right] .
\] (30)

We should compare this result \((N = 4)\) with the proposed 5D Casimir energy for the \(flat\) geometry (59). The component \(\sqrt{\tau^2 + \omega^2 \rho^2}\) in the integrand of (30) is replaced by \(\sqrt{\tau^2 + 1}\) in (59).

We recognize, if we start with

\[
ds^2 = \sum_{i=1}^N (dX^i)^2 + d\tau^2 \quad (N+1\ dim\ Euclidean\ flat) ,
\] (31)

instead of (22), the integration measure becomes \(exactly\) the same as (59).

4.2. Standard Type of \(N\) Harmonic Oscillators
Now we consider another type of \(N+1\) dim Euclidean space \((X^i, \tau); \ i = 1, 2, \ldots N\) described by the following line element.

\[
ds^2 = d\tau^{-2} \left\{ \sum_{i=1}^N (dX^i)^2 \right\}^2 + \omega^4 \left\{ \sum_{i=1}^N (X^i)^2 \right\}^2 d\tau^2 + 2\omega^2 \left\{ \sum_{i=1}^N (X^i)^2 \right\} \left\{ \sum_{j=1}^N (X^j)^2 \right\} d\tau^2
\]
\[
= \frac{1}{d\tau^2} \left\{ \sum_{i=1}^N (dX^i)^2 + \omega^2 r^2 d\tau^2 \right\}^2 , \quad r^2 = \sum_{i=1}^N (X^i)^2 ,
\] (32)
with the condition:

\[
\text{[Line Element Regularity Condition]} : \quad d\tau^2 \sim O(\epsilon^2) , \quad (dX^i)^2 \sim O(\epsilon^2) , \quad \frac{1}{d\tau^2} \{ \sum_{i=1}^{N} (dX^i)^2 \} \sim O(1) ,
\]

(33)
in order to keep all terms of (32) in the order of \(\epsilon^2\). Again we note that, in the above case, we do not have \(N+1\) dim (bulk) metric. We impose the periodicity (3): (period: \(\beta\)).

Here we take a path of Fig.3: \(\{ x^i(\tau) \mid 0 \leq \tau \leq \beta, i = 1, 2, \ldots, N \} \) and the induced metric on the path is given by

\[
X^i = x^i(\tau) , \quad dX^i = \dot{x}^i d\tau , \quad \dot{x}^i \equiv \frac{dx^i}{d\tau} , \quad 0 \leq \tau \leq \beta ,
\]

\[
ds^2 = \sum_{i=1}^{N} ( (\dot{x}^i)^2 + \omega^2 (x^i)^2 ) d\tau^2 .
\]

(34)

Then the length \(L\) of the path \(\{ x^i(\tau) \}\) is given by

\[
L[x^i(\tau)] = \int ds = \int_0^{\beta} \sum_{i=1}^{N} ( (\dot{x}^i)^2 + \omega^2 (x^i)^2 ) d\tau .
\]

(35)

Hence, taking \(\frac{1}{2}L\) as the Hamiltonian (minimal length principle), the free energy \(F\) of the system is given by

\[
e^{-\beta F} = \left( \prod_{i} \int_{-\infty}^{\infty} d\rho_i \right) \int x^i(0) = \rho_i \prod_{i,\tau} D x^i(\tau) \exp \left[ -\frac{1}{2} \int_0^{\beta} \sum_{i=1}^{N} ( (\dot{x}^i)^2 + \omega^2 (x^i)^2 ) d\tau \right] ,
\]

(36)

where the path-integral is done for all possible paths with the indicated b.c.. This is exactly the free energy of \(N\) harmonic oscillators.

We note again the condition (33) is necessary for the elastic view to the hyper-surfaces.

4.3. Middle type of \(O(N)\) nonlinear system

Instead of (32), we can start from a slightly modified metric.

\[
ds^2 = \omega^4 \left( \sum_{i=1}^{N} (X^i)^2 \right)^2 d\tau^2 + 2 \omega^2 \kappa \left\{ \sum_{i=1}^{N} (X^i)^2 \right\} \left\{ \sum_{j=1}^{N} (dX^j)^2 \right\}
\]

\[= \omega^2 r^2 \left( \omega^2 r^2 d\tau^2 + 2 \kappa \sum_{j=1}^{N} (dX^j)^2 \right) , \quad r^2 = \sum_{i=1}^{N} (X^i)^2 .
\]

(37)

We drop the first term of (32), and add a free (real) parameter \(\kappa\) in the third one. We stress that, in this case, we need not the condition of (33). The line element is the ordinary type and

\[^5\text{As in (8), this condition restricts the trajectory configuration (34) only to smooth hyper-surfaces in the (N+1)-dim space.}\]
we have the bulk metric $G_{AB}$ in this case. The Ricci tensor and the scalar curvature, for $N = 2$, are given by

$$
(R_{AB}) = \frac{1}{(r^2)^2} \begin{pmatrix}
4y^2 & -4xy & 0 \\
-4xy & 4x^2 & 0 \\
0 & 0 & 2\omega^2 (r^2)^2
\end{pmatrix}, \quad R = \frac{4}{\kappa \omega^2 (r^2)^2}, \quad r^2 = x^2 + y^2,
$$

$$
\sqrt{G} = 2\omega^4 |r|^4, \quad \sqrt{GR} = 8\omega^2 \cdot \text{sign}(\kappa), \quad (38)
$$

where $(X^1, X^2, X^3) = (x, y, \tau)$ and $\text{sign}(\kappa)$ is the sign of $\kappa$. \footnote{R > 0 \quad \text{for} \quad \kappa > 0, \quad R < 0 \quad \text{for} \quad \kappa < 0.}$ We consider the $N$ dim hypersurface (27), or Fig.4, and the \textit{induced} metric on it is given by

$$
ds^2 = \sum_{i,j=1}^{N} 2\omega^2 r^2 (\kappa \delta_{ij} + \frac{\omega^2}{2 r^2} x^i x^j) dx^i dx^j \equiv \sum_{i,j} g_{ij} dx^i dx^j. \quad (39)
$$

Then the \textit{area} of this hypersurface is given by

$$
A_N = \int \sqrt{\det g_{ij}} d^N x = \left(\frac{2\pi \omega^2 |\kappa|}{\Gamma(\frac{N}{2} + 1)} \right) \int_0^\beta r^N \sqrt{r^2 + \frac{r^2 \omega^2}{2|\kappa|}} r^{N-1} dr. \quad (40)
$$

Taking $\frac{1}{2} A_N$ as the Hamiltonian (\textit{minimal area principle}), the free energy, $F$, is given by

$$
e^{-\beta F} = \int_0^\infty d\rho \int_{r(0) = \rho} r(\beta) = \rho \prod_{\tau,i} D x^i(\tau) \exp \left[ -\frac{1}{2} \left(\frac{2\pi \omega^2 |\kappa|}{\Gamma(\frac{N}{2} + 1)} \right) \int_0^\beta r^N \sqrt{r^2 + \frac{r^2 \omega^2}{2|\kappa|}} r^{N-1} dr \right]. \quad (41)
$$

We should compare this result ($N=4, \kappa=1/2$) with the proposed 5D Casimir energy for the \textit{warped} geometry (59). They are similar ( $(\omega r)^4 \sqrt{r^2 + r^2 \omega^2}$ of (41) is replaced by $(1/\omega z)^4 \sqrt{r^2 + 1}$ of (59)).

\textbf{4.4. Modified type of $O(N)$ nonlinear system}

Instead of (37), we take the following type of metric.

$$
ds^2 = W(\tau) \left( V(r) d\tau^2 + \sum_{j=1}^{N} (dX^j)^2 \right), \quad r^2 = \sum_{i=1}^{N} (X^i)^2. \quad (42)
$$

Especially, if we start with $W(\tau) = 1/\tau^2, V(r) = 1$,

$$
\text{Euclidean (AdS)$_{N+1}$: \quad ds^2 = \frac{1}{\tau^2} (d\tau^2 + \sum_{j=1}^{N} (dX^j)^2)}, \quad (43)
$$

we recognize the integration measure \textit{exactly} becomes the same as that in (59): $\tau^{-N} \sqrt{r^2 + 1} \tau^{N-1} d\tau$.

The content in this section can be generalized for the \textit{general} isotropic potential.
5. Casimir Energy

One important application of the present approach is Casimir energy. As mentioned in the introduction, it requires careful regularization to define the quantity rigorously. In order to deal with divergence properly, the IR and UV regularizations are important. The final (finite) result depends on the boundary parameters only.

5.1. 4D Flat Case (Ordinary Casimir Energy)

Before explaining the original motivation (the 5 dim Casimir energy), we discuss the ordinary case (1+3 dim electromagnetism) and the relation to the present approach. We consider the electromagnetism in Minkowski space:

$$ds^2 = -dt^2 + dx^2 + dy^2 + dz^2.$$  \hspace{1cm} (44)

We place 2 perfectly-conducting plates parallel with the separation $2l$ in the x-direction. This configuration can be realized by taking the following boundary conditions. As for y- and z-directions, we impose the periodicity for the infra-red (IR) regularization.

Periodicity : $x \rightarrow x + 2l$, $y \rightarrow y + 2L$, $z \rightarrow z + 2L$, \hspace{1cm} $L \gg l$,  \hspace{1cm} (45)

where $L$ is the IR-regularization parameter. Then the eigen frequencies of the electromagnetic wave and Casimir energy are given by

$$\omega_{n,m_y,m_z} = \sqrt{(n \pi \over l)^2 + (m_y \pi \over L)^2 + (m_z \pi \over L)^2},$$

$$E_{\text{Cas}} = 2 \cdot \sum_{n,m_y,m_z \in \mathbb{Z}} \frac{1}{2} \omega_{n,m_y,m_z} \geq 0,$$  \hspace{1cm} (46)

where $\mathbb{Z}$ indicates all integers. $\frac{1}{2} \omega_{n,m_y,m_z}$ is the zero-point oscillation energy. Introducing the cut-off function $g(x) (= 1$ for $0 < x < 1$, $0$ for otherwise), Casimir energy can formally be written as

$$E_{\text{Cas}}^\Lambda = \sum_{n,m_y,m_z \in \mathbb{Z}} \omega_{n,m_y,m_z} g \left( \frac{\omega_{n,m_y,m_z}}{\Lambda} \right) \geq 0.$$  \hspace{1cm} (47)

We take the continuum limit $L \rightarrow \infty$, $L \ll l \rightarrow \infty$.

$$E_{\text{Cas}}^{\Lambda_0} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dk_x dk_z \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dk_y}{\pi} \sqrt{k_x^2 + k_y^2 + k_z^2} g \left( \frac{k}{\Lambda} \right)$$

$$= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dk_x dk_y dk_z \left( \frac{2}{\pi} \right)^{3/2} \frac{2}{\pi} \sqrt{k_x^2 + k_y^2 + k_z^2} \geq 0.$$  \hspace{1cm} (48)

Note that $E_{\text{Cas}}$, $E_{\text{Cas}}^{\Lambda}$ and $E_{\text{Cas}}^{\Lambda_0}$ are all positive-definite.

In a familiar way, regarding $E_{\text{Cas}}^{\Lambda_0}$ as the origin of the energy scale, we consider the quantity $u = (E_{\text{Cas}}^{\Lambda} - E_{\text{Cas}}^{\Lambda_0}) / (2L)^2$ as the physical Casimir energy and evaluate it with the help of the Euler-MacLaurin formula as $u = (\pi^2 / (2l)^3) (B_4 / 4!) = -\pi^2 / (720) (1 / (2l))^3 < 0$.\footnote{$B_4 = -1/30$ is the 4-th Bernoulli number.} The final result is negative. In the present analysis we take a new regularization.
First we re-express $E_{\text{Cas}}^0$ using a simple identity: $l = \int_0^l dw$ ($w$: a regularization or 'extra' axis).

\[
E_{\text{Cas}}^0/(2L)^2 = \frac{1}{2\pi^3} \int_0^l dw \int_{k \leq \Lambda} P(k) 2\pi k^2 dk \\
= \frac{1}{2\pi^3} \int_0^l dw (-1) \int_{r \geq \Lambda^{-1}} P(1/r)(-1) 2\pi r^{-4} dr .
\]

where the integration variable changes from the momentum ($k$) to the coordinate ($r = \sqrt{x^2 + y^2 + z^2}$). The integration region in $(R, w)$-space is the infinite rectangular shown in Fig.5.

![Figure 5](image1.png)  
**Figure 5.** The integral region of (49).

![Figure 6](image2.png)  
**Figure 6.** A general path $r(w)$ of (50) and a periodic path $r(w)$ of (51).

We regularize the above expression using the path-integral as

\[
E_{\text{Cas}}^{\mathcal{W}}/(2L)^2 = \frac{1}{2\pi^3} (2\pi) \int_{\text{all paths}} dr(w) \\
\prod_w Dr(w) \left[ \int dw' P\left( \frac{1}{r(w')} \right) r(w')^{-4} \right] \exp \left\{ -\mathcal{W}[r(w)] \right\} ,
\]

where the integral is over all paths $r(w)$ which are defined between $0 \leq w \leq l$ and whose value is above $\Lambda^{-1}$, as shown in Fig.6.

$\mathcal{W}[r(w)]$ is some damping functional explained in the next paragraph. The case $\mathcal{W}[r(w)] = 0$ corresponds to (49). The slightly-more-restrictive regularization is

\[
E_{\text{Cas}}^{\mathcal{W}}/(2L)^2 = \frac{1}{2\pi^3} (2\pi) \int_{\Lambda^{-1}}^\infty dp \int_{r(0) = r(l) = \rho} dr(w) \\
\prod_w Dr(w) \left[ \int dw' P\left( \frac{1}{r(w')} \right) r(w')^{-4} \right] \exp \left\{ -\mathcal{W}[r(w)] \right\} \geq 0 ,
\]

where the integral is over all *periodic* paths. Note that the above regularization keep the positive-definite property.
Hence the present regularization mainly defined by the choice of $W[r(w)]$. In order to specify it, we introduce the following metric in $(R, w)$-space.

$$ds^2 = \frac{1}{dw^2}(dR^2 + \Omega^2 R^2 dw)^2$$

This is the same as that in Sec.2.2. On a path $R = r(w)$, the induced metric and the length $L$ is given as follows. As the damping functional $W[r(w)]$, we take the length $L$.

$$ds^2 = dw^2(r'^2 + \Omega^2 r^2)^2 , \quad r' \equiv \frac{dr}{dw} , \quad L = \int ds = \int (r'^2 + \Omega^2 r^2)dw , \quad W[r(w)] = \frac{1}{2\alpha}L = \frac{1}{2\alpha} \int (r'^2 + \Omega^2 r^2)dw$$

The two parameters $\alpha$ and $\Omega$ are considered as regularization ones. The limit $\alpha \to \infty$ corresponds to (49).

Numerical calculation can evaluate $E_{Cas}^{W}(51)$, and we expect the following form[24, 25].

$$E_{Cas}^{W}(52) = \frac{a}{l^3}(1 - 3c \ln (\Lambda))$$

where $a$ and $c$ are some constants. $a$ should be positive because of the positive-definiteness of (51). The present regularization result has, like the ordinary renormalizable ones such as the coupling in QED, the log-divergence. The divergence can be renormalized into the boundary parameter $l$. This means $l$ flows according to the renormalization group.

$$l' = l(1 - 3c \ln(\Lambda))^{-\frac{1}{3}}, \quad \beta \equiv \frac{d\ln(l'/l)}{d\ln \Lambda} = c, \quad |c| \ll 1$$

where $\beta$ is the renormalization group function, and we assume $|c| \ll 1$. The sign of $c$ determines whether the length separation increases ($c > 0$) or decreases ($c < 0$) as the measurement resolution becomes finer ($\Lambda$ increases). In terms of the usual terminology, attractive case corresponds to $c > 0$, and repulsive case to $c < 0$.

5.2. 5D Flat and Curved Case

Let us mention the space-time quantization (quantum gravity) in relation to the motivation of the present work. The space-time geometry is specified by the metric tensor field $g_{\mu\nu}(x)$ which appears in the definition of the line element $(ds^2)_{4D} = g_{\mu\nu}(x)dx^\mu dx^\nu \quad (\mu, \nu = 0, 1, 2, 3)$. One of most important problems of the present theoretical physics is the clarification of the quantum role of the metric (gravitational) field $g_{\mu\nu}$. We already have a long (nearly half century) history of the quantum gravity since Feynman[20] and DeWitt [21] pioneered. About one decade ago, inspired by the development of the string theory and the D-brane theory, a fascinating model of unification of forces was proposed. It is a 5 dimensional(dim) model with AdS$_5$ geometry and is called ”Randall-Sundrum model” or the ”warped model”[22]. This is a representative of the extra dimensional models. An important purpose of the present work is to make this 5 dim model legitimate as the quantum field theory.

In the warped space-time, the geometry is described as

$$\text{Warped Metric (y-expression)} \quad ds^2 = e^{-2\omega|y|}\eta_{\mu\nu}dx^\mu dx^\nu + dy^2, \quad -l \leq y \leq l$$

where $\{\mu, \nu = 0, 1, 2, 3\}$, $(\eta_{\mu\nu}) = \text{diag}(-1, 1, 1, 1)$. The coordinate $y$ is called the extra coordinate. The parameter $\omega$ is the 5 dim (bulk) scalar curvature. $l$ is the size parameter
of the extra coordinate. We respect the periodicity: \( y \to y + 2l \), and \( Z_2 \)-parity: \( y \leftrightarrow -y \). Instead of \( y \), another coordinate \( z \) is also used. \(^8\)

Warped Metric (\( z \)-expression) \( ds^2 = \frac{1}{\omega^2 z^2} (\eta_{\mu\nu} dx^\mu dx^\nu + dz^2) = G_{MN} dx^M dx^N \),

\[ |z| = \frac{1}{\omega} e^{\omega |y|} , \quad \frac{1}{\omega} < |z| < \frac{1}{T} \quad \text{,} \quad T \equiv \omega e^{-\omega l} \]

\[ R_{MN} = 4\omega^2 G_{MN} \quad , \quad R = 20\omega^2 > 0 \quad , \quad \sqrt{-G} = \sqrt{-\det G_{MN}} = \left( \frac{1}{\omega |z|} \right)^3 \quad , \quad (57) \]

where \((X^M) \equiv \{ x^\mu, z \} \), \( \{ M, N = 0, 1, 2, 3, 5 \} \). \(^9\) The flat (5D Minkowski) limit is obtained by \( \omega \to 0 \) in the \( y \)-expression (56).

Flat Metric \( ds^2 = \eta_{\mu\nu} dx^\mu dx^\nu + dy^2 \), \((X^M) = (x^\mu, y)\), \(-l \leq y \leq l\) \quad , \quad (58)

Traditional calculation\(^{[23, 24, 25]}\) gives the \( \Lambda^5 \)-divergent result for Casimir energy, on the above geometries, of 5D models. In the calculation, Casimir energy is expressed as the 5D space-momentum integral \( \int d^4 p d y d z \) or \( \int d^4 p d z \) of some energy (density) function \( F(\vec{p}, y) \) or \( F(\vec{p}, z) \). (See Appendix for detail.) In ref.\(^{[24, 25]}\), we claim the \( \Lambda^5 \)-divergence comes from this ‘naive’ integration measure and should be replaced by some proper measure, based on close numerical calculation using some trial integration measures. Finally, Casimir energy of the free fields (electromagnetism, free scalar theory) is proposed to be replaced by the following path-integral.

For Flat Geometry :

\[ -\mathcal{E}_{Cas}(l, \Lambda) = \int_{1/\Lambda}^l d\rho \int_{r(0)=r(l)=\rho} \prod_{a,y} D x^a(y) \left[ \int dy' F_1 \left( \frac{1}{r(y')}, y' \right) \right] \]

\[ \times \exp \left[ -\frac{1}{2\alpha^2} \int_0^l \sqrt{r^2 + 1} r^3 dy \right] \quad , \quad r' = \frac{dr}{dy} \]

For Warped Geometry :

\[ -\mathcal{E}_{Cas}(\omega, T, \Lambda) = \int_{1/\Lambda}^{1/\Lambda} d\rho \int_{r(1/\omega)=r(1/T)=\rho} \prod_{a,z} D x^a(z) \left[ \int dz' F_2 \left( \frac{1}{r(z')}, z' \right) \right] \]

\[ \times \exp \left[ -\frac{1}{2\alpha^2} \int_{1/\omega}^{1/T} \frac{1}{\omega^4 z^4} \sqrt{r^2 + 1} r^3 dz \right] \quad , \quad r' = \frac{dr}{dz} \quad , \quad (59) \]

where \( r = \sqrt{\sum_{a=1}^4 (x^a)^2} \). \(^{10}\) \( \{ x^a | a = 1, 2, 3, 4 \} \) is the Euclideanized coordinates of \( \{ x^\mu | \mu = 0, 1, 2, 3 \} \). \( x^0 = ix^4 \) \( \). \( F_1 \) and \( F_2 \) are some energy density functions and will appear in Appendix \(( (A.2) \) and \( (A.4) )\). \( \Lambda \) is the UV-cutoff parameter, \( \mu \equiv \Lambda T/\omega \) is the IR-cutoff one and \( l \) is the

\(^8\) \( z \) is defined by \( y \) as

\[ z = \begin{cases} \frac{1}{2} e^{\omega y} & y > 0 \\ 0 & y = 0 \\ -\frac{1}{2} e^{-\omega y} & y < 0 \end{cases} \]

\(^9\) \( T \) is not a temperature parameter but a IR parameter like \( l \) \( (T = \omega e^{-\omega l}) \). The temperature appears as \( \beta^{-1} \). See eq. (3).

\(^{10}\) The case \( \alpha' \to \infty \) in (59) is essentially the traditional definition of Casimir energy.
periodicity (IR) one. Note that the above expressions of $-\mathcal{E}_{\text{Cas}}$ are positive-definite. The above path-integrals are over all paths of 4 dim hypersurfaces defined by

Flat Geometry:
$$\sqrt{\sum_{a=1}^{4}(x^a)^2} = r(y), \quad -l \leq y \leq l,$$

Warped Geometry:
$$\sqrt{\sum_{a=1}^{4}(x^a)^2} = r(z), \quad \frac{1}{\omega} \leq |z| \leq \frac{1}{T}.$$  \hspace{1cm} (60)

See Fig. 7 for the case of the N+1 dim space. This is a closed string configuration. The area (4D volume) plays the role of Hamiltonian of the quantum statistical system $\{x^a\}$. $F_i$ comes from the matter-field quantization and plays a role of the energy 'operator' in the path-integral over the 4D hyper-surface $r(y)$ or $r(z)$. The string (surface) tension parameter $1/2\alpha'$ is introduced. The new point, compared with the 5D Casimir energy calculation so far [23], is the introduction of the 'minimal area' factor $\exp\left(-\frac{1}{2\alpha'} \text{Area}\right) = \exp\left(-\frac{1}{2\alpha'} \int \sqrt{\det(g_{ab})}d^4x\right)$ where $g_{ab}$ is the induced metric on the hyper-surface (60). We have shown, in this paper, the above-type path-integral very naturally appears in many quantum-statistical systems when we view them geometrically. The proposed quantities (59) are shown to be valid.

The proposed expressions (59) of 5D Casimir energy can be evaluated numerically. We confirmed, not using the path-integral but using some effective approach (weight-function method), that they are given by as follows.

Flat:
$$\frac{\mathcal{E}_{\text{Cas}}(l, \Lambda)}{\Lambda l} = -\frac{a}{l^4} \left(1 - 4c \ln(l\Lambda)\right), \quad a \sim 2.5, \quad c > 0, \quad c \sim O(10^{-3}).$$

Warped:
$$\frac{\mathcal{E}_{\text{Cas}}(\omega, T, \Lambda)}{\Lambda T^{-1}} = -a\omega^4 \left(1 - 4c_1 \ln\left(\frac{\Lambda}{\omega}\right) - 4c_2 \ln\left(\frac{T}{\omega}\right)\right),$$
$$a \sim 1.2, \quad c_1 \sim -0.11 < 0, \quad c_2 \sim 0.10 > 0.$$  \hspace{1cm} (61)

The boundary parameters flow as

Flat:
$$\frac{\mathcal{E}_{\text{Cas}}(l, \Lambda)}{\Lambda l} = -\frac{a}{l^4}, \quad \beta = \frac{\partial}{\partial(\ln \Lambda)} \ln \frac{l'}{l} = c > 0,$$

Warped:
$$\frac{\mathcal{E}_{\text{Cas}}(\omega, T, \Lambda)}{\Lambda T^{-1}} = -a\omega^4, \quad \beta = \frac{\partial}{\partial(\ln \Lambda)} \ln \frac{\omega'}{\omega} = -c_1 - c_2.$$  \hspace{1cm} (62)
\( \beta = c > 0 \) in the flat case means the size of the extra world (periodicity \( l \)) shrinks as the measurement resolution becomes coarse. This image fits with the compactification of the extra axis in the higher-dimensional unified models.

6. Visco-Elastic System

The present approach gives a new method for the study of the visco-elastic system. Let us explain it using the harmonic oscillator with friction.

\[
\dot{m}\ddot{x} = -kx - \eta \dot{x}, \quad k: \text{ spring constant, } \eta: \text{ viscosity}.
\]  

From this we obtain the "energy" at \( t = t_0 \).

\[
\mathcal{E} = \left( \frac{1}{2}m\dot{x}^2 + \frac{\omega_1^2}{2}x^2 \right) |_{t_0} = \frac{1}{2}\dot{x}_0^2 + \frac{\omega_1^2}{2}x_0^2 + \eta \int_{t_0}^{t} \left( \frac{dx(t)}{dt} \right)^2 dt, \quad \omega_1 = \frac{k}{m}, \quad \eta = \frac{\eta}{m}.
\]  

This quantity is conserved (independent of \( t \)). The hysteresis term in the above expression represents the energy from the friction force. We can read the line elements in \((X, t)\) space for this system.

\[
\text{Dirac type: } ds^2 = dX^2 + dt^2 \left( \frac{1}{2} \omega_1^2 X^2 + 2\eta \int_{t_0}^{t} \frac{dx(t)}{dt}^2 dt \right),
\]

\[
\text{Standard type: } ds^2 = \frac{1}{dt^2} \left( dX^2 + dt^2 \left( \frac{1}{2} \omega_1^2 X^2 + 2\eta \int_{t_0}^{t} \frac{dx(t)}{dt}^2 dt \right) \right)^2.
\]

On a path \( X = x(t) \), with the standard type, the length \( L[x(t)] \) and the free energy \( F \) is given by \((t_0 = 0)\)

\[
L[x(t)] = \int ds = \int_{0}^{\beta} dt \{ \dot{x}^2 + \omega_1^2 x^2 + 2\eta \int_{t_0}^{t} \left( \frac{dx(t)}{dt} \right)^2 dt \},
\]

\[
e^{-\beta F(l, \beta)} = \int_{-l}^{l} d\rho \int_{x(0) = \rho, x(\beta) = \rho} \mathcal{D}x(t) e^{-\frac{1}{2}L[x(t)]},
\]

where \( 2l \) is the periodicity, with which we impose \( X \) periodic.

\[
X \to X + 2l.
\]

The energy \( E \), the entropy \( S \) and the force \( f \) are given by

\[
\text{Energy } E(l, \beta) = \frac{L}{2}, \quad \text{Entropy } S(l, \beta) = k_B \beta (E(l, \beta) - F(l, \beta)) \quad \text{Force } f(l, \beta) = -\frac{\partial E(l, \beta)}{\partial l},
\]

where \( k_B \) is Boltzmann’s constant.

The simple model (63) can be generalized as

\[
m\ddot{x} = -\frac{\partial V(x)}{\partial x} - \eta_1 \dot{x}W_1(x) - \eta_2 \dot{x}^2 W_2(x),
\]
where we assume the visco-elastic system is in the relatively slow motion. This assumption makes the velocity($\dot{x}$)-expansion of (69) valid. $V(x), W_1(x), W_2(x)$ are general functions. There are many choices:

$$V(x) = \frac{1}{2} k x^2 \text{ (spring)}, \quad g(x) \text{ (rain-drop)}, \cdots$$

$$W_1(x) = 1 \quad x^2 - 1 \text{ (van der Pol eq.)}, \cdots$$

$$W_2(x) = 1 \quad x \quad x^2, \quad x^3, \cdots$$

(70)

The line elements in $(X, t)$ space is given by

'Dirac' type :

$$ds^2 = m dX^2 + dt^2 \left\{ 2 V(X) + 2 \eta_1 \int_{t_0}^{t} (dX)^2 \frac{1}{dt} W_1(X) + 2 \eta_2 \int_{t_0}^{t} \left( \frac{dX}{dt} \right)^2 W_2(X) \right\},$$

Standard type :

$$ds^2 = \frac{1}{dt^2} \left[ m dX^2 + dt^2 \left\{ 2 V(X) + 2 \eta_1 \int_{t_0}^{t} (dX)^2 \frac{1}{dt} W_1(X) + 2 \eta_2 \int_{t_0}^{t} \left( \frac{dX}{dt} \right)^2 W_2(X) \right\} \right]^2.$$  (71)

The above formulas are valid for the spacially-circling 1-dim visco-elastic fluid (Fig.8). The global (statistical) physical quantities can be expressed by the path-integral in the same way as eq.(68).

For the spacially 3 dim visco-elastic system, we treat Navier-Stokes equation (1). We obtain the following relation.

$$\frac{D}{Dt} \left( \frac{\rho}{2} \dot{v}^2 + P - \rho \ddot{x} \cdot \ddot{g} \right) = \frac{\partial P}{\partial t} + \eta \dot{v} \Delta \dot{v}.$$  (72)

From this, we obtain, for the case $\frac{\partial P}{\partial t} = 0$,

$$\mathcal{E} = \left( \frac{\rho}{2} \dot{v}^2 + P - \rho \ddot{x} \cdot \ddot{g} \right) |_{t_0} = \frac{\rho}{2} \dot{v}^2 + P - \rho \ddot{x} \cdot \ddot{g} - \eta \int_{t_0}^{t} \dot{v} \Delta \dot{v} \, dt.$$  (73)

We can read, from the above result, the following line elements.

Dirac type :

$$ds^2 = \rho \, dX^2 \frac{1}{2} + dt^2 \left\{ 2 P(X) - 2 \rho X \dot{g}^2 - 2 \eta \int_{t_0}^{t} dX^2 \frac{1}{dt} \Delta (dX) \frac{1}{dt} \right\},$$

Standard type :

$$ds^2 = \frac{1}{dt^2} \left[ \rho \, dX^2 + dt^2 \left\{ 2 P(X) - 2 \rho X \dot{g}^2 - 2 \eta \int_{t_0}^{t} dX^2 \frac{1}{dt} \Delta (dX) \frac{1}{dt} \right\} \right]^2.$$  (74)
On a path $X^i = x^i(t)$, with the standard type, the length $L[\vec{x}(t)]$ and the free energy $F$ are given by ($t_0 = 0$)

$$L[\vec{x}(t)] = \int ds = \int_0^\beta dt \left\{ \rho(\vec{x})^2 + 2P(\vec{x}) - 2\rho\vec{x} \cdot \vec{g} - 2\eta \int_0^t \dot{\vec{x}}^2 \Delta \dot{\vec{x}} \, dt \right\} ,
$$

$$e^{-\beta F(l,\beta)} = \int d\rho_1 \int d\rho_2 \int d\rho_3 \int_{x^i(0)=x^i(\beta)=0} Dx^i(t) e^{-\frac{1}{\beta}L[\vec{x}(t)]} , \quad (75)$$

where $2l$ is the periodicity, with which we impose $X^i$ periodic.

$$X^i \rightarrow X^i + 2l \quad (i = 1, 2, 3) . \quad (76)$$

### 7. Discussion and Conclusion

Inspired by the recent new views on the quantum gravity, we have presented a geometrical approach to the general quantum statistical system. The idea lies in the introduction of the metric in the space of Feynman’s path-integral. The length or the area gives the system Hamiltonian. In the application to 5D Casimir energy, the inverse temperature (or proper time) axis is played by the extra (5th) one. In the 4D case (ordinary Casimir energy), the regularization axis plays the role. Casimir force is explained from the renormalization group flow. The attractive force or the repulsive one corresponds to the positive $\beta$-function or the negative one. This geometrical approach also gives a new method to examine the dissipative system caused by friction. Taking simple visco-elastic models, we elaborate on how to choose the metric and present the path-integral expressions of the statistical quantities such as energy and entropy.

### Appendix A. Traditional Definition of Casimir Energy in 5D Theories

The traditional definition of Casimir Energy of the 5D electromagnetic field theory is, for the flat case (58),

$$e^{-tE_{Cas}} = \int DA \exp \left[ i \int d^4 x dy (L_{EM}^{5D} + L_{gauge}) \right]_{\text{Euclid}} ,$$

$$L_{EM}^{5D}[A_M(X)] = -\frac{1}{4} F_{MN} F^{MN} , \quad F_{MN} = \partial_M A_N - \partial_N A_M , \quad L_{gauge}[A_M(X)] = -\frac{1}{2} (\partial_M A^M)^2 . \quad (A.1)$$

The expression of $E_{Cas}$ defined above, is given by

- For Flat Geometry (5 dim electromagnetism) :

$$E_{Cas}(l) = \int_{p\leq\Lambda} \frac{d^4 p}{(2\pi)^4} \int_0^l dy \left( F^-_f (\vec{p}, y) + 4F^+_f (\vec{p}, y) \right) ,$$

$$F^\mp_f (\vec{p}, y) = -\int_0^\infty dk \frac{\mp \cosh k (2y - l) + \cosh kl}{2 \sinh (kl)} . \quad (A.2)$$

The plus-minus symbol, $\mp$, indicates the contribution from $Z_2$-parity odd (-) and even (+) components. $\vec{p}$ is the maginitude of 4D momentum $(p_0, p_1, p_2, p_3, p_4)$. The coincidence with the previous result[23] was confirmed[24]. As for the warped case (57), the traditional definition, for the 5D free scalar theory, is given by

$$e^{-T^4 E_{Cas}} = \int D\Phi \exp \left[ i \int d^5 x \sqrt{-g} L_{s}^{5D} \right]_{\text{Euclid}}$$

$$= \int D\Phi(X) \exp \left[ \int d^4 x dz \frac{1}{(\omega z)^2} \frac{1}{2} \Phi \left( \omega^2 z^2 \partial_0 \partial^0 \Phi + (\omega z)^5 L_s \Phi \right) \right] ,$$
\[ L_s^{5D}[\Phi(X); X] = -\frac{1}{2} \nabla^M \Phi \nabla_M \Phi - \frac{1}{2} m^2 \Phi^2, \]
\[ \frac{1}{\omega} < |z| < \frac{1}{T}, \quad \hat{L}_z = \frac{d}{dz} \left( \frac{1}{\omega z} \right)^3 \frac{d}{dz} - \frac{m^2}{(\omega z)^5}, \quad (m^2 = -4\omega^2). \]  

where \( \hat{L}_z \) is the kinetic operator in the extra space (Bessel differential operator). Casimir energy \( E_{Cas} \) defined in (A.3) is explicitly given by

\[ -E_{Cas}^\mp(\omega, T) = \int d^4pE \left| \int_{\omega}^{1/T} dz \ F_w^\mp(\hat{p}, z) \right| \]
\[ G_p^\mp(z, z') = (\frac{1}{2}) \left\{ \right. \]
\[ \left. \begin{array}{c}
I_0(\frac{\hat{p}}{z})K_0(\hat{p}z) \mp K_0(\frac{\hat{p}}{z'})I_0(\hat{p}z') \pm K_0(\frac{\hat{p}}{z'})I_0(\hat{p}z')
\end{array} \right\}, \]
\[ \langle \hat{L}_z - p^2s(z)\rangle G_p^\mp(z, z') = \begin{cases} 
\epsilon(z)\epsilon(z')\delta(|z| - |z'|) & \text{for } P = -1 \\
\delta(|z| - |z'|) & \text{for } P = 1 
\end{cases} \]

where \( I_0 \) and \( K_0 \) are the modified Bessel functions of 0-th order.

Acknowledgments

Parts of the content of this work have been already presented at the international conference on "Particle Physics, Astrophysics and Quantum Field Theory" (08.11.27-29, Nanyang Executive Centre, Singapore)[26]; First Mediterranean Conference on Classical and Quantum Gravity (09.9.14-18, Kolymbari, Crete, Greece)[27], Int. Workshop on "Strong Coupling Gauge Theories in LHC Era" (09.12.8-11, Nagoya Univ., Nagoya, Japan)[28], and IPMU Workshop on 'Condensed Matter Physics Meets High Energy Physics' (10.2.8-12, IMPU, Univ. of Tokyo, Kashiwa, Japan). The author thanks the audience for useful comments and encouragement on the occasions.
