High expression of osteoglycin decreases gelatinase activity of murine hepatocarcinoma Hca-F cells

Xiao-Nan Cui, Jian-Wu Tang, Bo Song, Bo Wang, Shan-Yan Chen, Li Hou

AIM: To investigate the possible correlation between osteoglycin expression and gelatinase activity of mouse hepatocarcinoma Hca-F cells.

METHODS: A eukaryotic expression plasmid pIRESpuro3 osteoglycin(+) was constructed and transfected into Hca-F cells to investigate the possible correlation between osteoglycin expression and gelatinase activity of Hca-F cells cultured with extract of lymph node, liver, spleen or in DMEM medium. The activity of gelatinases was examined through zymographic analysis.

RESULTS: High expression of osteoglycin attenuated the gelatinase activity of Hca-F cells cultured with extract of lymph node, liver, spleen or in DMEM medium. The activity of gelatinases was examined through zymographic analysis.

CONCLUSION: High expression of osteoglycin decreases the gelatinase activity of Hca-F cells cultured with extract of lymph node; regulation of gelatinase activity might be one of mechanisms that osteoglycin contributes to lymphatic metastasis suppression.

Key words: Osteoglycin; Transfection; Hepatocellular carcinoma; Neoplasm metastasis; Genes; Gelatinases

INTRODUCTION

Most cancer lesions metastasize through the lymphatic system and the status of regional lymph nodes is the most important indicator of a patient’s prognosis[1]. But the molecular mechanism of lymphatic metastasis remains unclear. Hca-P and Hca-F are syngeneic mouse hepatocarcinoma cell lines, when inoculated subcutaneously in 615-mice, they metastasized only to the lymph nodes but not to other organs, Hca-P cells illustrated a low metastatic potential (lymphatic metastasis rate < 30%), while Hca-F cells showed a high metastatic potential (lymphatic metastasis rate > 80%)[2,3]. In our previous study, we found that osteoglycin was highly expressed in Hca-P cells and lowly expressed in Hca-F cells with suppressively subtracted hybridization (SSH) technique. Osteoglycin (OGN) is a member of proteoglycans (PGs) called small leucine-rich proteoglycans (SLRPs) residing in the extracellular matrix of connective tissues which are involved in matrix assembly, cellular growth and migration[4]. There are few reports about the relationship between osteoglycin and tumor metastasis. We subsequently transfected osteoglycin into Hca-F cells and found that high expression of osteoglycin inhibited the metastatic behavior of Hca-F cells[5]. However, the mechanism of osteoglycin regulating metastasis is elusive.

Gelatinases/type IV collagenases belong to matrix metalloproteinase (MMP) family, including gelatinase A (also known as MMP2, 72 kDa) and gelatinase B (also known as MMP9, 92 kDa), they are secreted in a proenzyme form and activated extracellularly[6]. Gelatin-
ases mainly degrade collagen IV and a number of other ECM proteins, such as Col I, V, VIII, IX, fibronectin, laminin, elastin and vitronectin[8]. As the most frequently studied MMPs in tumor research, gelatinases are suggested to play critical roles in tumor invasion and metastasis[8].

In this study, we resorted to gene transfection technique to explore the possible correlation between osteoglycin expression and gelatinase activity of murine hepatocarcinoma Hca-F cells with a high metastatic potential. We found that high expression of osteoglycin decreased the gelatinase activity of Hca-F cells cultured with extract of lymph node, and at the same time, decreased the metastatic potential of Hca-F cells to peripheral lymph nodes in vivo; regulation of gelatinase activity might be one of mechanisms that osteoglycin contributes to lymphatic metastasis suppression.

MATERIALS AND METHODS

Cell culture and animals
Mouse hepatocarcinoma Hca-P cells and Hca-F cells (established by Department of Pathology, Dalian Medical University) were cultured in DMEM (Invitrogen) supplemented with antibiotics (1 × penicillin/streptomycin 100 U/mL, Invitrogen), 10% FBS (Invitrogen) and cultured in a humidified incubator at 37°C with 50 mL/L CO2; inbred 615-mice (male, 8 wk old) were provided by Animal Facility of Dalian Medical University.

Construction of targeting vector
The osteoglycin coding sequence was amplified by polymerase chain reaction (PCR). Briefly, total RNA from 1 × 10^7 Hca-F cells was isolated with Trizol (Invitrogen). A High Fidelity PrimeScript RT-PCR kit (TaKaRa) was used to synthesize the cDNA according to the manufacturer's protocol. PCR was carried out with primer sets P1, 5'-GAATTCATGGAGACCTGACTCTGACCTA-3' (forward), and P2, 5'-GGCTCCGGCCTAGAAATGTA GCCTA-3' (reverse), containing EcoR I and Not I sites, respectively (underlined). Using obtained cDNA as a template, PCR was carried out under the following conditions: 30 cycles of denaturation for 10 s at 98°C, annealing for 15 s at 55°C, and extension for 60 s at 72°C. After digestion by EcoR I and Not I enzymes, the PCR product was cloned into pIRESpuro3 vector digested by the same enzymes and designated as pIRESpuro osteoglycin(+). Sequence and orientation were confirmed by DNA sequencing using a BigDye Terminator V3.1 cycle sequencing kit (Applied Biosystems).

Cell transfection and screening
Hca-F cells incubated in antibiotic-free medium with 10% FBS (Invitrogen) were transferred to a 6-well culture plate and incubated at 37°C, CO2 incubator to obtain 60%-80% confluence, and then were stably transfected with pIRESpuro3 and pIRESpuro3 osteoglycin(+) using TransIT-LT1 Transfection Reagent (TaKaRa) according to the protocol provided by the manufacturer. Two µg plasmid DNA was added to each transfection. The transfected Hca-F cells were selected by puromycin (Clontech) for 2 wk and maintained in medium containing 0.5 mg/L puromycin.

RT-PCR analysis
For RT-PCR analysis of osteoglycin mRNA levels, total RNA was isolated from cells using Trizol (Invitrogen) and cDNA was synthesized with High Fidelity PrimeScript™ RT-PCR Kit (TaKaRa) according to the manufacturer's instruction. The sequences of the primers were as follows: F1: 5'-TTCTCTCGCTACTCTTCGTG-3' and R1: 5'-AAAGACAGACACAACAGGCA-3' for osteoglycin; and F1: 5'-CNGGACCTGACAGACTACCC TA-3' and R1: 5'-AGCAGCTGTGTGGCGATAGAG-3' for β-actin, respectively. PCR analysis was performed under the following conditions: 30 cycles of denaturation for 10 s at 98°C, annealing for 15 s at 55°C, and extension for 30 s at 72°C. The amplified products were analyzed by agarose gel electrophoresis using 1.6% gel, followed by ethidium bromide staining. The bands were analyzed with LabWorks (UVP GDS-800 Version 4.0).

Western blotting analysis
Western blotting analysis was carried out to evaluate osteoglycin protein levels. Cellular protein was extracted with lysis buffer [20 mmol/L Tris (pH 7.5), 150 mmol/L NaCl, 1 mmol/L MgCl2, 2 mmol/L EGTA, 10% glycerol, 0.15% sodium dodecylsulfate, 1% deoxycholate, 1% Triton X-100, and 1% anti-protease cocktail (Sigma)]. The extracted proteins were subjected to 10% sodiumdodecylsulfate-polyacrylamide gel electrophoresis, blotted onto polyvinylidene difluoride membranes (Invitrogen), then probed with goat anti-mouse osteoglycin polyclonal antibody and β-actin monoclonal antibody (Santa Cruz) followed by secondary antibody conjugated to horseradish peroxidase (Santa Cruz) and detected by enhanced chemiluminescence (Amersham Biosciences). The bands were analyzed with LabWorks (UVP GDS-800 Version 4.0).

In vivo tumor metastasis assay
Ninety inbred 615-mice were randomly divided into 3 groups. Hca-F cells (F), Hca-F cells transfected with pIRESpuro3 (F0), or Hca-F cells transfected with pIRESpuro3 osteoglycin(+) [F(+)] were inoculated subcutaneously at 2 × 10^6 tumor cells of approximately 0.05 mL cell suspension into the left foot of each mouse in each group. They were terminated on the 28th day after inoculation, the implanted tumor and their axillary lymph nodes, inguinal lymph nodes, and popliteal lymph nodes were hematoxylin eosin (HE) stained and examined under microscope. The mouse which had at least one metastatic axillary lymph node or one metastatic inguinal lymph node or one metastatic popliteal lymph node was considered as a metastatic mouse. The lymph node metastatic rate of tumor-burden mice = metastatic mice/total mice.

The lymph node metastatic rates of F, F0 and F(+) cells burden mice were also evaluated. The number of positive lymph nodes per mouse was also evaluated.
Zymographic analysis

The F, Hca-P (P), F0 and F(+) cells were put into different wells at 5 × 10^5, and then added 50 mg extract of lymph node, liver or spleen respectively. The Dulbecco's Modified Eagle Media (DMEM) was placed into each well up to 1 mL. DMEM medium containing only F, P, F0 or F(+) cells, and DMEM medium added only extracts of lymph node, liver or spleen served as controls. These cells were cultured at 37°C for 24 h. The supernatant of cultured cells was collected by centrifugation at 3000 × g. Gelatinases contained in supernatants of each cell with or without extracts of lymph node, liver or spleen were detected through zymographic analysis according to the method described by Fridman[9]. The bands were analyzed with LabWorks (UVP GDS-800 Version 4.0).

Statistical analysis

Data were presented as means ± SD and analyzed by the Student's t test, analysis of variance and χ² test using SPSS 11.5. P < 0.05 was considered statistically significant.

RESULTS

Osteoglycin expression at mRNA and protein level

The relative mRNA and protein levels of osteoglycin were determined by RT-PCR and Western blotting analysis, respectively. Compared with F and F0 cells, F(+) cells showed significantly higher expression of osteoglycin at both mRNA and protein levels; however, no significant difference of osteoglycin expression was found between F0 and F cells. Transfection of osteoglycin into Hca-F cells resulted in high expression of osteoglycin at both mRNA and protein levels. Osteoglycin was highly expression at both mRNA and protein levels in P cells (Figure 1).

In vivo tumor metastasis assay

F, F0 and F(+) cells were injected subcutaneously into the left foot of 615-mice. The implanted tumors were palpable on the 7th day after inoculation. On the 28th day after inoculation, 53.3% (16/30, F) cells burden mice developed lymphatic metastasis, while 80% (24/30, F) cells burden mice and 83.3% (25/30, F0) cells burden mice developed lymphatic metastasis. Hca-F cells with transfected osteoglycin showed significant decrease in metastasis potential to lymph node (Figure 2). The result supported the fact that osteoglycin acted as a tumor lymphatic metastasis suppressed gene.

No significant difference was found in the number of positive lymph nodes per mouse in F(+) and F0 cells burden mice.

Zymographic analysis

When cultured in DMEM, no cell produced any gelatinase (no gelatinase was detected in the supernatant of each cell). However, when cultured with extract of lymph node, all cells produced gelatinases (Pro-MMP-9, MMP-9 active, Pro-MMP-2 and MMP-2 active were detected in the supernatant of each cell). The quantity of gelatinases produced by tumor cells were closely associated with the metastatic potential of each tumor cell (quantity of MMP2 and MMP9 detected in the supernatant of F and F0 cells were much higher than those detected in F(+) and P cells (P < 0.05). High expression of osteoglycin via transfection of osteoglycin attenuated the secretion of gelatinases in Hca-F cells cultured with extract of lymph node (quantities of MMP2 and MMP9 detected in the supernatant of F(+) cells were much lower than those detected in F and F0 cells (P < 0.05). The extract of lymph node did not contain any gelatinase (Figure 3). Gelatin lysis bands were found in the zymograms of the supernatant of all cells cultured with extract of liver, and the same gelatin lysis bands were found in the zymograms of the extract of liver, and their intensities were almost the same (Figure 4); gelatin lysis bands were also found in the

Cui XN et al. Osteoglycin and murine hepatocarcinoma Hca-F cells 6119
zymograms of the supernatant of all cells cultured with extract of spleen, and in the zymograms of the extract of spleen, with similar intensities (Figure 5). Therefore, we think that all cells in the liver and spleen did not produce any gelatinases.

DISCUSSION

The metastatic potential of tumor cells is believed to be regulated by interactions between the tumor cells and their extracellular environment (extracellular matrix)[10,11]. Being a matrix molecule, osteoglycin participates in the organization and regulation of the extracellular matrix and might influence the tumor metastasis, as exemplified by studies in vivo that osteoglycin played a role in collagen fibrillogenesis[12,13], a process essential in metastasis[12,13]. In addition to its extracellular matrix functions, osteoglycin, like other members of SLRPs, also plays a role in regulation of cell biological behavior[4]. As illustrated in the literature, the expression of mimecan was high at mRNA level in cornel keratocytes cultured in low-serum or serum-free media, but was attenuated if these cells were cultured in media containing serum[14]. Osteoglycin mRNA was absent or at a low level in the majority of cancer cell lines and tumors[15]. Bioactive such as p53, basic fibroblast growth factor, interferon-γ and bone morphogenetic protein-1/tolloid-related metalloproteinases interacted with osteoglycin[16-20]. In the earlier studies, we found that osteoglycin was highly expressed in Hca-P cells and lowly expressed in Hca-F cells, and that osteoglycin acted as a tumor lymphatic metastasis suppressed gene[5]. However, no data identified intrinsic mechanism for osteoglycin regulation of tumor lymphatic metastasis.

Hca-P and Hca-F are syngenetic mouse hepato-

www.wjgnet.com
carcinoma cell lines presenting a specific potential of lymphatic metastasis with a significant difference in their potential of metastasis\(^{[2,3]}\), which provide good experimental models for lymph node metastasis.

Cell adhesion to extracellular matrices is a determinant for cell migration and invasion\(^{[21,22]}\). Osteoglycin, being a matrix molecule, as we once assumed, would probably affect adhesive capacity of tumor cells, whereby influencing tumor migration and invasion. However, our previous work showed that adhesion was not responsible for the contribution of osteoglycin to lymphatic metastasis inhibition\(^{[3]}\). As the main mediators of extracellular matrix degradation, gelatinases play an important role in tumor metastasis as demonstrated in gastrointestinal cancer\(^{[23,24]}\), breast cancer\(^{[25]}\), hepatocarcinoma\(^{[26]}\), etc. Inhibition of the gelatinase activity can reduce the metastatic potential of cancer cells\(^{[27]}\). In the present study, high expression of osteoglycin via osteoglycin transfection attenuated the secretion of gelatinases (Pro-MMP-9, MMP-9 active, Pro-MMP-2 and MMP-2 active) in Hca-F cells cultured with extract of lymph node, and at the same time, decreased the metastatic potential of Hca-F cells to peripheral lymph nodes in vivo, which suggested that regulation of gelatinase activity might be one of mechanisms that osteoglycin contributes to lymphatic metastasis suppression. Moreover, osteoglycin expression only influenced gelatinase activity of Hca-F cells cultured with extract of lymph node, but failed to influence gelatinase activity of Hca-F cell cultured with extracts of liver and spleen or in DMEM medium, demonstrating a lymph node environment-selective metastasis suppression, which further supported the fact that osteoglycin acted as lymphatic metastasis suppression gene. The mechanism of osteoglycin impact on gelatinases is unclear. Some of the SLRPs members bind and modulate TGF-\(\beta\) and cytokines such as TNF-\(\alpha\)\(^{[28,29]}\) and play roles in EGFR activation pathway and the NF-\(\kappa\)B signal transduction system as well\(^{[30,31]}\). And these bioactivities (TGF-\(\beta\), TNF-\(\alpha\), EGF and NF-\(\kappa\)B) are also the regulators of gelatinase activity\(^{[6,32]}\), which implicates that SLRPs might involve in the regulation of gelatinase activity. Further studies are needed to clarify the interaction between gelatinases and osteoglycin.
