Abstract

We analyse two-dimensional Schrödinger operators with the potential $|xy|^p - \lambda (x^2 + y^2)^{p/(p+2)}$ where $p \geq 1$ and $\lambda \geq 0$. We show that there is a critical value $\lambda_c$ such that the spectrum for $\lambda < \lambda_c$ is bounded below and purely discrete, while for $\lambda > \lambda_c$ it is unbounded from below. In the subcritical case, we prove upper and lower bounds for the eigenvalue sums.

1. Introduction

While the idea of Hermann Weyl to analyse the spectra of quantum systems semiclassically, by looking at the phase space allowed for the corresponding classical motion, is one of the most seminal in modern mathematical physics, its validity is not universal. Various examples of systems which have a purely discrete spectrum despite the fact that the respective phase space volume is infinite were constructed in the last three decades. A classical one belongs to Simon \cite{Si83} and describes a two-dimensional Schrödinger operator with the potential $|xy|^p$ having deep ‘valleys’ the width of which is shrinking with the distance from the origin. A related problem concerns spectral properties of Dirichlet Laplacians in regions with hyperbolic cusps—we refer to the recent paper \cite{GW11} for an up-to-date bibliographical survey.

The aim of this paper is two-fold. First, we want to demonstrate that similar spectral behaviour can also occur for Schrödinger operators with potentials unbounded from below. Furthermore, we intend to construct a model which exhibits a nontrivial spectral transition as the coupling constant changes. Specifically, we are going to consider here the following class of operators,

\begin{equation}
L_p(\lambda) : L_p(\lambda) \psi = -\Delta \psi + (|xy|^p - \lambda (x^2 + y^2)^{p/(p+2)}) \psi, \quad p \geq 1,
\end{equation}

\[1751-8113/12/075204+14$33.00 © 2012 IOP Publishing Ltd Printed in the UK & the USA\]
on $L^2(\mathbb{R}^2)$ using the standard Cartesian coordinates $(x, y)$ in $\mathbb{R}^2$; the parameter $\lambda$ in the second term of the potential is non-negative. Unless the value of $\lambda$ is important in a particular context, we denote the operator simply as $L_p$. Since $2p < 2$, the operator (1.1) is essentially self-adjoint on $C_0^\infty(\mathbb{R}^2)$ by the Faris–Lavine theorem—cf [RS75], theorems X.28 and X.38; in the following the symbol $L_p$ or $L_p(\lambda)$ will always mean its closure.

First, we will show that there is a critical value of the coupling constant $\lambda$, expressed explicitly as a ground-state eigenvalue of the corresponding (an)harmonic oscillator Hamiltonian, such that the spectrum of $L_p(\lambda)$ is below bounded and purely discrete for $\lambda < \lambda_{\text{crit}}$, while for $\lambda > \lambda_{\text{crit}}$ it becomes unbounded from below. In the latter case, one naturally expects it to be continuously covering the whole real axis but we will not proceed this way. The main results of the paper are upper and lower bounds to the sums of the first $N$ eigenvalues of $L_p(\lambda)$ in the subcritical case proved in section 3. They give the same asymptotics up to a multiplicative constant if $\lambda = 0$, while for $\lambda > 0$ this remains true for the leading term but an additional one, linear in $N$, is added in the lower bound. The proof of the upper bound is reduced to the case $\lambda = 0$; hence, it is not surprising that the result holds for any $\lambda < \lambda_{\text{crit}}$. On the other hand, the argument which yields the lower bound is more subtle and we have been able to prove the result for sufficiently small values of $\lambda$ only leaving room for improvement, see theorem 3.1 below. In section 4, we also prove a lower bound to spectral sums of the operator $-\Delta_1 - \lambda(x^2 + y^2)$ for $0 \leq \lambda < 1$, where $-\Delta_1$ is the Dirichlet Laplacian on the region with hyperbolic cusps; formally speaking this can be regarded as the limit $p \to \infty$ of the problem (1.1).

2. Discreteness of the spectrum

The first important observation is that the spectral properties of the operator $L_p(\lambda)$ depend crucially on the value of the parameter $\lambda$; we have to distinguish two cases.

2.1. The subcritical case

The spectral regime we are primarily interested in occurs for small values of $\lambda$. To characterize the smallness quantitatively we need an auxiliary operator which will be an (an)harmonic oscillator Hamiltonian on line,

$$\tilde{H}_{p} : \tilde{H}_{p}u = -u'' + |t|^p u$$

on $L^2(\mathbb{R})$ with the standard domain. Let $\gamma_p$ be the minimal eigenvalue of this operator; in view of the potential symmetry we have $\gamma_p = \inf \sigma(H_p)$, where

$$H_p : H_pu = -u'' + t^p u$$

on $L^2(\mathbb{R}^+)$ with the Neumann condition at $t = 0$. This quantity is known exactly for $p = 2$ where it equals 1 as well as for $p \to \infty$ where the potential becomes an infinitely deep rectangular well of width 2 and $\gamma_\infty = \frac{1}{4} \pi^2$; it smoothly interpolates between the two values. It is not difficult to estimate it from below: since $x^p \geq 1 - x(0,1)(x)$, it follows from the minimax principle that

$$\gamma_p \geq \epsilon_0 \approx 0.546,$$

where $\epsilon_0$ is the ground-state energy of the corresponding rectangular potential well of depth 1. It is only a crude estimate; a numerical solution shows that the true minimum $\gamma_p \approx 0.998$ is reached at $p \approx 1.788$—cf figure 1. We have the following result.

Since the letters $x, y$ are used for the Cartesian coordinates we employ the symbol $t$ for a generic spatial variable as is customary in the theory of ordinary differential equations.
Figure 1. $\gamma_p$ as a function of $p$ in the semilogarithmic scale.

**Theorem 2.1.** For any $\lambda \in [0, \lambda_{\text{crit}})$, where $\lambda_{\text{crit}} := \gamma_p$, the operator $L_p(\lambda)$ is bounded from below for any $p \geq 1$; if $\lambda < \gamma_p$ its spectrum is purely discrete.

**Proof.** Suppose first that $\lambda < \gamma_p$. By the minimax principle it is sufficient to estimate $L_p$ from below by a self-adjoint operator with a purely discrete spectrum. To construct such a lower bound, we employ bracketing imposing additional Neumann conditions at concentric circles of radii $n = 1, 2, \ldots$. Using the standard polar coordinates, we thus obtain a direct sum of operators acting as

$$
L_{n,p}^{(1)} \psi = -\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial \psi}{\partial r} \right) - \frac{1}{n^2} \frac{\partial^2 \psi}{\partial \varphi^2} + \left( \frac{r^2}{2p} |\sin 2\varphi|^p - \lambda r^{2p/(p+2)} \right) \psi, \tag{2.4}
$$

$$
\left. \frac{\partial \psi}{\partial n} \right|_{r=n-1} = \left. \frac{\partial \psi}{\partial n} \right|_{r=n} = 0, \tag{2.5}
$$
on the annular regions $G_n := \{(r, \varphi) : n-1 \leq r < n, \ 0 \leq \varphi < 2\pi\}, \ n = 1, 2, \ldots$. Each of the latter is compact and the potential is regular on it; hence $\sigma(L_{n,p}^{(1)})$ is purely discrete. It is sufficient therefore to check that $\inf \sigma(L_{n,p}^{(1)}) \to \infty$ as $n \to \infty$ because then the spectrum of $\bigoplus_{n=1}^{\infty} L_{n,p}^{(1)}$ below any fixed value is a finite union of discrete spectra which implies the sought claim.

The argument can be simplified further if we estimate $L_{n,p}^{(1)}$ from below by an operator with separating variables acting, for instance, as

$$
L_{n,p}^{(2)} \psi = -\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial \psi}{\partial r} \right) - \frac{1}{n^2} \frac{\partial^2 \psi}{\partial \varphi^2} + \left( \frac{(n-1)^2}{2p} \sin 2\varphi|^p - \lambda n^{2p/(p+2)} \right) \psi,
$$

$$
\left. \frac{\partial \psi}{\partial n} \right|_{r=n-1} = \left. \frac{\partial \psi}{\partial n} \right|_{r=n} = 0,
$$
the spectrum of which is the ’sum’ of the radial and angular components. Furthermore, the lowest radial eigenfunction is zero corresponding to a constant eigenfunction; hence, the problem reduces to the analysis of the angular component of the above operator; using
the mirror symmetries of the potential it is enough to consider it on \( L^2(0, \pi/4) \) with Neumann conditions at the endpoints of the interval.

To simplify things further we take an arbitrary \( \varepsilon \in (0,1) \) and introduce the following ordinary differential operator on \( L^2(0, \pi/4) \),

\[
L_{n,p}^{(3)} : L_{n,p}^{(3)} u = -u'' + \left( \frac{2^{p+2}}{2^p} \right)^p \sin^p 2x - \frac{\lambda}{1 - \varepsilon} n^{(4p+4)/(p+2)} u,
\]

with Neumann boundary conditions, \( u'(0) = u'(\pi/4) = 0 \). It is clear that for \( n \) large enough, specifically \( n > \left( 1 - (1 - \varepsilon)^{p+2}/(4p+4) \right)^{-1} \), we have \( n^p L_{n,p}^{(2)} \geq L_{n-1,p}^{(3)} \); hence, it is sufficient to investigate the spectral threshold \( \mu_{n,p} \) of \( L_{n,p}^{(3)} \). We employ one more estimate from below. To a fixed \( \varepsilon \) there is \( \delta(\varepsilon) \) such that \( \sin 2x \geq 2(1 - \varepsilon)x \) holds for \( 0 \leq x \leq \delta(\varepsilon) \). We consider the operator

\[
L_{n,p}^{(4)} := -\frac{d^2}{dx^2} + n^{2p+2} \chi_{(0,\delta(\varepsilon))}(x) + \left( \frac{2}{\pi} \right)^p \chi_{(\delta(\varepsilon), \pi/4)}(x) - \lambda' \mu_{n,p}^{(4p+4)/(p+2)}
\]

with Neumann boundary conditions, where \( \lambda'_\varepsilon := \lambda (1 - \varepsilon)^{-p-1} \), and denote its lowest eigenvalue as \( \mu_{n,p}' \). In view of the inequality \( \sin x \geq \frac{2}{\pi} x \) we have \( L_{n,p}^{(3)} \geq (1 - \varepsilon)^p L_{n,p}^{(4)} \), and thus \( \mu_{n,p} \geq (1 - \varepsilon)^p \mu_{n,p}' \), \( n = 1, 2, \ldots \), by the minimax principle. It is therefore sufficient to check that

\[
\frac{\mu_{n,p}'}{n^2} \to \infty \quad \text{as} \quad n \to \infty. \tag{2.6}
\]

It is straightforward to check that the operator \( L_{n,p}^{(4)} \) without the last term is by a simple scaling transformation, \( x = t \cdot n^{-(p+2)/(p+2)} \), unitarily equivalent to the \( \nu_p^1 \) multiple of the operator

\[
H_{n,p} = -\frac{d^2}{dt^2} + t^p \left( \chi_{(0,\delta(\varepsilon))}(t) + \left( \frac{2}{\pi} \right)^p \chi_{(\delta(\varepsilon), \pi/4)}(t) \right)
\]

on \( L^2(0, \frac{1}{t} \nu_p^1) \) with Neumann conditions at the endpoints of the interval, where \( \nu_p := n^{(2p+2)/(p+2)} \). The spectrum of the above operator is purely discrete, and denoting by \( \gamma_{n,p} \) its lowest eigenvalue, we thus have

\[
\mu_{n,p}' = (\gamma_{n,p} - \lambda'_\varepsilon)n^{(4p+4)/(p+2)}.
\]

Furthermore, we have \( H_{n,p}^N \leq H_{n,p} \leq H_{n,p}^D \) where the estimating operators act as (2.7) with additional Neumann and Dirichlet condition, respectively, at the point \( t = \nu_p \delta(\varepsilon) \). For large enough \( n \), the ground states of both estimating operators come from the ‘inner’ part, \( t \in (0, \nu_p \delta(\varepsilon)) \), and one can check explicitly that \( \gamma_{n,p} \to \gamma_p \) as \( n \to \infty \) for both \( j = N, D \), where \( \gamma_p \) is the ground state of (2.2), and therefore \( \gamma_{n,p} \to \gamma_p \) as \( n \to \infty \). This further implies that to any positive \( \varepsilon' \) there is a natural number \( n_{\varepsilon} \) such that

\[
(\gamma_p - \lambda'_\varepsilon - \varepsilon')n^{(4p+4)/(p+2)} \leq \mu_{n,p}' \leq (\gamma_p - \lambda'_\varepsilon + \varepsilon')n^{(4p+4)/(p+2)}
\]

holds for \( n > n_{\varepsilon} \). Since \( \varepsilon \) and \( \varepsilon' \) are arbitrary we conclude that (2.6) holds for any \( p \geq 1 \) whenever \( \lambda < \gamma_p \), which establishes the claim. If \( \lambda = \gamma_p \) the sequence no longer diverges but it remains bounded from below and the same is by the minimax principle true for the operator \( L_\lambda(\lambda) \).

2.2. The supercritical case

For large values of \( \lambda \) the picture changes.

**Proposition 2.1.** The spectrum of \( L_\lambda(\lambda) \), \( p \geq 1 \), is unbounded below if \( \lambda > \lambda_{crit} \).
Proof. We employ a similar technique, this time looking for an upper estimate to $L_p(\lambda)$. We construct it by Dirichlet bracketing considering the operators acting as (2.5) on the annular domains $G_n$, denoted again as $L_{1,n}^{(1)}$, this time with Dirichlet boundary conditions, $\psi|_{\partial G_n} = 0$. We have $\bigoplus_{n=1}^{\infty} L_{1,n}^{(1)} \geq L_p(\lambda)$; hence, by the minimax principle we have to prove that
\[
\inf \sigma (L_{1,n}^{(1)}) \to -\infty \quad \text{as} \quad n \to \infty.
\]
We estimate $L_{1,n}^{(1)}$ from above by an operator with separated variables acting as
\[
L_{n,p}^{(2)} \psi = -\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial \psi}{\partial r} \right) - \frac{1}{(n-1)^2} \frac{\partial^2 \psi}{\partial \varphi^2} + \left( \frac{n^2}{2p} \sin 2\varphi - \lambda (n-1)^2p^{(p+2)} \right) \psi
\]
on $H^2$ functions satisfying $\psi(n-1, \varphi) = \psi(n, \varphi) = 0$ for all $\varphi \in [0, 2\pi)$. The contribution from the radial term is now nonzero, and moreover, it depends on $n$; however, it is uniformly bounded. Specifically, the spectral threshold of $-\frac{1}{2} p^2 r^2 \frac{\partial^2}{\partial r^2}$ on $L^2(n-1, n)$ with the Dirichlet condition does not exceed $\pi^2$, the bound being saturated as $n \to \infty$ [EFK04]. Consequently, it is sufficient to check that the spectral threshold of the angular part or of a suitable one-dimensional operator estimating it from above tends to $-\infty$ as $n \to \infty$.

The argument is similar to the one used in the previous proof. We fix $\varepsilon \in (0, 1)$ and analyse the operator acting as
\[
L_{n,p}^{(2)} u = -u''(\varphi) + \left( \frac{n^2}{2p} \sin 2\varphi - (1 - \varepsilon)\lambda n^{(4p+4)/(p+2)} \right) u
\]
on $L^2(0, \pi/4)$ with Neumann conditions at the endpoints of the interval. Using the inequality $\sin x \leq x$ on $[0, \pi/4]$ and the unitary equivalence given by the same scaling transformation as in the previous case we reduce the problem to the investigation of the operator $v_p^2 H_{n,p}$, where $H_{n,p} u = -u'' + t^2 u$ on $L^2(0, \frac{1}{2}v_p \pi)$ with Neumann conditions at the endpoints. Denoting $\mu_{n,p} := \inf \sigma (L_{n,p}^{(2)})$ we find in the same way as above that to any $\varepsilon' > 0$ there is a natural $n_{\varepsilon'}$ such that
\[
(y_p - (1 - \varepsilon)\lambda - \varepsilon') n^{(4p+4)/(p+2)} \leq \mu_{n,p} \leq (y_p - (1 - \varepsilon)\lambda + \varepsilon') n^{(4p+4)/(p+2)}
\]
holds for all $n > n_{\varepsilon'}$. Since $\lambda > y_p$ by assumption and $\varepsilon$, $\varepsilon'$ are arbitrary, the second inequality yields the desired result. □

3. Spectral estimates

Now we can pass to our main subject which is estimating eigenvalue sums of the operator (1.1) for small values of the coupling constant $\lambda$.

3.1. Lower bounds to eigenvalue sums

To state our result on lower bounds on the spectrum we introduce the following quantity:
\[
\alpha := \frac{1}{2} (1 + \sqrt{5})^2 \approx 5.236.
\]
It is clear from (2.3) that $\alpha^{-1} < y_p$. We denote by $[\lambda_{j,p}]_{j=1}^{\infty}$ the eigenvalues of $L_p(\lambda)$ arranged in ascending order; then we can make the following claim.

Theorem 3.1. To any non-negative $\lambda < \alpha^{-1}$ there exists a positive constant $C_p$ depending on $p$ only such that the following estimate is valid:
\[
\sum_{j=1}^{N} \lambda_{j,p} \geq C_p (1 - \alpha \lambda) \frac{N^{(2p+1)/(p+1)}}{(\ln N + 1)^{(1)/(p+1)}} - c \lambda N, \quad N = 1, 2, \ldots, \quad (3.1)
\]
where $c = 2 \left( \frac{\alpha}{\alpha - 1} + 1 \right) \approx 15.7$.  

5
Proof. We denote by \( \{ \psi_{j,p} \}^\infty_{j=1} \) the system of normalized eigenfunctions corresponding to \( \{ \lambda_{j,p} \}^\infty_{j=1} \), i.e. we have
\[
- \Delta \psi_{j,p} + (|x|^p - \lambda (x^2 + y^2)^{(p+2)/2}) \psi_{j,p} = \lambda_{j,p} \psi_{j,p}, \quad j = 1, 2, \ldots ;
\]
without loss of generality we may assume that the functions \( \psi_{j,p} \) are real-valued. Our potential forms hyperbolic-shaped ‘valleys’ and our first task will be to find estimates on eigenfunction integrals in some corresponding regions. Specifically, we are going to demonstrate that for any natural number \( j \) and a positive \( \delta \) one has
\[
\int_1^\infty \int_0^{(1+\delta)\gamma^{\gamma/(p+2)}} y^{2p/(p+2)} \psi_{j,p}^2(x, y) \, dx \, dy \leq 2 (1 + \delta)^2 \int_1^\infty \int_0^{\infty} \left( \frac{\partial \psi_{j,p}}{\partial x} \right)^2 (x, y) \, dx \, dy
\]
and that for an arbitrary \( \varepsilon > 0 \) there is a number \( 1 \leq \Theta (\varepsilon) \leq 1 + \delta \) such that
\[
\int_1^\infty \int_0^{\gamma^{\gamma/(p+2)}} y^{p/(p+2)} \psi_{j,p}^2 \left( \frac{\Theta (\varepsilon)}{y^{\gamma/(p+2)}}, y \right) \, dy < \frac{1}{\delta} \int_1^\infty \int_0^{(1+\delta)\gamma^{\gamma/(p+2)}} x^{p} y^{p} \psi_{j,p}^2 (x, y) \, dx \, dy + \varepsilon .
\]
Changing variables in the integral on the right-hand side we obtain
\[
\int_1^\infty \int_0^{(1+\delta)\gamma^{\gamma/(p+2)}} x^{p} y^{p} \psi_{j,p}^2 (x, y) \, dx \, dy
\]
which proves the validity of inequality (3.3). Let us proceed to the proof of inequality (3.2). We fix a positive \( \varepsilon \) and the corresponding number \( \Theta (\varepsilon) \). In view of the Newton–Leibnitz theorem and Cauchy’s inequality we have
\[
\int_1^\infty \int_0^{(1+\delta)\gamma^{\gamma/(p+2)}} y^{2p/(p+2)} \psi_{j,p}^2 (x, y) \, dx \, dy
\]

\[
+ \int_1^\infty \int_{\theta(x)y^{-\eta/p+2}}^{(\theta(x)y^{-\eta/p+2})^2} y^{2p/(p+2)} \left( \int_0^x y^{\theta(x)y^{-\eta/p+2}} \frac{\partial \psi_j^{p,\theta}}{\partial t} (t, y) \, dt \right) \, dx \, dy
\]

\[
+ \psi_j^{p,\theta}(\theta(x)y^{-\eta/p+2}, y) \right)^2 \, dx \, dy
\]

\[
\leq 2 \int_1^\infty \int_0^{\theta(x)y^{-\eta/p+2}} y^{2p/(p+2)} \left( \int_0^x \frac{\partial \psi_j^{p,\theta}}{\partial t} (t, y) \, dt \right) \, dx \, dy
\]

\[
+ 2 \int_1^\infty \int_0^{(\theta(x)y^{-\eta/p+2})^2} y^{2p/(p+2)} \psi_j^{p,\theta}(\theta(x)y^{-\eta/p+2}, y) \, dx \, dy
\]

\[
+ 2 \int_1^\infty \int_{\theta(x)y^{-\eta/p+2}}^{(\theta(x)y^{-\eta/p+2})^2} y^{2p/(p+2)} \left( \int_0^x \frac{\partial \psi_j^{p,\theta}}{\partial t} (t, y) \, dt \right) \, dx \, dy
\]

\[
+ 2 \int_1^\infty \int_{\theta(x)y^{-\eta/p+2}}^{(\theta(x)y^{-\eta/p+2})^2} y^{2p/(p+2)} \psi_j^{p,\theta}(\theta(x)y^{-\eta/p+2}, y) \, dx \, dy
\]

\[
\leq 2 \theta(\epsilon) \int_1^\infty \int_0^{\theta(x)y^{-\eta/p+2}} y^{\theta(x)y^{-\eta/p+2}} \left( \frac{\partial \psi_j^{p,\theta}}{\partial t} \right)^2 (t, y) \, dt \, dx \, dy
\]

\[
+ 2 \theta(\epsilon) \int_1^\infty \int_0^{\theta(x)y^{-\eta/p+2}} y^{\theta(x)y^{-\eta/p+2}} \left( \frac{\partial \psi_j^{p,\theta}}{\partial t} \right)^2 (t, y) \, dt \, dx \, dy
\]

\[
+ 2(1 + \delta - \theta(\epsilon)) \int_1^\infty \int_{\theta(x)y^{-\eta/p+2}}^{(\theta(x)y^{-\eta/p+2})^2} y^{\theta(x)y^{-\eta/p+2}} \left( \frac{\partial \psi_j^{p,\theta}}{\partial t} \right)^2 (t, y) \, dt \, dx \, dy
\]

\[
\leq 2(1 + \delta) \int_1^\infty \int_0^1 y^{\delta/(p+2)} \psi_j^{p,\theta}(\theta(x)y^{-\eta/p+2}, y) \, dx \, dy
\]

\[
+ 2(1 + \delta) \int_1^\infty \int_0^1 y^{\delta/(p+2)} \left( \frac{\partial \psi_j^{p,\theta}}{\partial t} \right)^2 (t, y) \, dt \, dx \, dy
\]

\[
+ 2(1 + \delta) \int_1^\infty \int_0^1 \psi_j^{p,\theta}(\theta(x)y^{-\eta/p+2}, y) \, dx \, dy
\]

Furthermore, by virtue of inequality (3.3) we infer that

\[
\int_1^\infty \int_0^1 y^{\delta/(p+2)} \psi_j^{p,\theta}(x, y) \, dx \, dy \leq 2(1 + \delta) \int_1^\infty \int_0^1 \left( \frac{\partial \psi_j^{p,\theta}}{\partial x} \right)^2 (x, y) \, dx \, dy
\]

\[
+ 2 \frac{1 + \delta}{\delta} \int_1^\infty \int_0^1 y^{\delta/(p+2)} \psi_j^{p,\theta}(x, y) \, dx \, dy + 2(1 + \delta)\epsilon.
\]
from which, using the arbitrariness of \( \varepsilon \), the validity of inequality (3.2) follows. In the same way one proves
\[
\int_1^{\infty} \int_0^{1+(\lambda^2)^{\gamma-\delta/2}} x^2 \int_0^{(p+2)} \rho^2 \hat{\psi}_{j,p}^2(x, y) \, dy \, dx \leq 2(1+\delta)^2 \int_1^{\infty} \int_0^{1+(\lambda^2)^{\gamma-\delta/2}} \left( \frac{\partial \hat{\psi}_{j,p}}{\partial y} \right)^2 (x, y) \, dy \, dx
\]
\[
+ \frac{1+\delta}{\delta} \int_1^{\infty} \int_0^{1+(\lambda^2)^{\gamma-\delta/2}} x^2 \rho^2 \hat{\psi}_{j,p}^2(x, y) \, dy \, dx
\]
and analogous bounds for the other hyperbolic ‘valleys’ where \( x \) or \( y \) takes negative values. Using the fact that \( \| \hat{\psi}_{j,p} \| = 1 \) in combination with simple estimates we obtain
\[
\int_{\mathbb{R}^2} (x^2 + y^2)^{\gamma/2} \hat{\psi}_{j,p}^2(x, y) \, dx \, dy 
\]
\[
\leq \left( \int_{|y| > 1} \int_{|x| < (1+\delta)|y|^{\gamma/2}} |y|^{2p/(p+2)} \hat{\psi}_{j,p}^2(x, y) \, dx \, dy 
\right)
\]
\[
+ \left( \int_{|y| > 1} \int_{|x| > (1+\delta)|y|^{\gamma/2}} |y|^{2p/(p+2)} \hat{\psi}_{j,p}^2(x, y) \, dx \, dy 
\right)
\]
\[
+ \left( \int_{|y| > 1} \int_{|x| < (1+\delta)|y|^{\gamma/2}} |x|^{2p/(p+2)} \hat{\psi}_{j,p}^2(x, y) \, dx \, dy 
\right)
\]
\[
+ \left( \int_{|y| > 1} \int_{|x| > (1+\delta)|y|^{\gamma/2}} |x|^{2p/(p+2)} \hat{\psi}_{j,p}^2(x, y) \, dx \, dy 
\right)
\]
\[
+ \left( \int_{|y| > 1} \int_{|x| > (1+\delta)|y|^{\gamma/2}} |x|^{2p/(p+2)} \hat{\psi}_{j,p}^2(x, y) \, dx \, dy 
\right)
\]
\[
\leq 2(1+\delta) \max \left( (1+\delta), \frac{1}{\delta} \right) \left( \int_{\mathbb{R}^2} |\nabla \hat{\psi}_{j,p}|^2 (x, y) \, dx \, dy 
\right)
\]
\[
+ \int_{\mathbb{R}^2} |xy|^p \hat{\psi}_{j,p}^2 (x, y) \, dx \, dy + (1+\delta)^2 \right) + 2,
\]
where we have used the fact that \(|xy|^p > |y|^{2p/(p+2)}|x|^{\gamma/2}\) holds on the domain of the second one of the four integrals, and a similar bound holds \textit{a fortiori} for the fourth one; the factor \((1+\delta)^2\) prevents us from double counting the ‘corner regions’ with \(|x|, |y| \geq 1\) and \(|y| \leq (1+\delta)|x|^{\gamma/2}\).

Choosing \( \delta = \frac{1+\sqrt{5}}{2} \) we obtain
\[
\int_{\mathbb{R}^2} (x^2 + y^2)^{\gamma/2} \hat{\psi}_{j,p}^2(x, y) \, dx \, dy \leq \alpha \left( \int_{\mathbb{R}^2} |\nabla \hat{\psi}_{j,p}|^2 (x, y) \, dx \, dy + \int_{\mathbb{R}^2} |xy|^p \hat{\psi}_{j,p}^2 (x, y) \, dx \, dy \right) + c,
\]
where \( c := \alpha(1+\delta)^2 + 2 = 2 \left( \frac{\alpha \lambda}{\lambda} + 1 \right) \). Since \( \lambda_{j,p} \) is the eigenvalue corresponding to the eigenfunction \( \psi_{j,p} \), the last relation implies
\[
\int_{\mathbb{R}^2} |\nabla \psi_{j,p}|^2 \, dx \, dy + \int_{\mathbb{R}^2} |xy|^p \psi_{j,p}^2 \, dx \, dy \leq \frac{1}{1 - \alpha \lambda} (\lambda_{j,p} + c \lambda), \quad j = 1, 2, \ldots.
\]
We subtract a number \( \rho \) from both sides of the last equation and express the first integral through the Fourier–Plancherel image of \( \psi_{j,p} \). Summing over the first \( N \) eigenvalues we obtain
\[
- \sum_{j=1}^{\infty} \int_{\mathbb{R}^2} (\rho - x^2 - y^2)|\hat{\psi}_{j,p}|^2 \, dx \, dy + \sum_{j=1}^{\infty} \int_{\mathbb{R}^2} |xy|^p \psi_{j,p}^2 \, dx \, dy \leq \frac{1}{1 - \alpha \lambda} \sum_{j=1}^{N} (\lambda_{j,p} + c \lambda) - N \rho,
\]
and the inequality will certainly remain valid if we replace \( \rho = x^2 - y^2 \) by its positive part \([\rho = x^2 - y^2]^+\). We need the following auxiliary result.
There is a constant $C_p$ such that for any orthonormal system of real-valued functions, $\Phi = \{\psi_j\}_{j=1}^N \subset L^2(\mathbb{R}^2)$, $N = 1, 2, \ldots$, the inequality
\[
\int_{\mathbb{R}^2} \rho_n^{p+1} \ dx \ dy \leq C_p (\ln^p N + 1) \sum_{j=1}^N \int_{\mathbb{R}^2} |\xi\eta|^p |\psi_j|^2 \ d\xi \ d\eta.
\]
holds true, where $\rho_n := \sum_{j=1}^N \psi_j^2$.

This claim was proved as theorem 2 in [Bar09] for $p = 1$; its extension to any $p \geq 1$ is straightforward. Combining it with the Hölder inequality, we obtain the following estimate for the system $\Phi = \{\psi_j, \rho_j\}_{j=1}^N$:
\[
-\left( \int_{\mathbb{R}^2} |\varrho - x^2 - y^2|^{p+1} \ dx \ dy \right)^{\frac{1}{p+1}} \left( \int_{\mathbb{R}^2} \rho_p^{p+1} \ dx \ dy \right)^{\frac{1}{p+1}} \leq \frac{C_p}{1 + \ln^p N} \int_{\mathbb{R}^2} \rho_p^{p+1} \ dx \ dy
\]
where $\alpha = \frac{1}{1 - \alpha_p \lambda} \sum_{j=1}^N (\lambda_{j,p} + c\lambda) - N\varrho$.

Consider the function $f : f(z) = -\left( \int_{\mathbb{R}^2} |\varrho - x^2 - y^2|^{(p+1)/p} \ dx \ dy \right)^{p/(p+1)} z + \frac{c_p}{1 + \ln^p N} z^{p+1}$.

It is easy to verify that its minimum is attained at the point $z_0 = z_0(p)$, where
\[
z_0 = \left( \frac{1 + \ln^p N}{p + 1} \right)^{1/p} \left( \int_{\mathbb{R}^2} |\varrho - x^2 - y^2|^{(p+1)/p} \ dx \ dy \right)^{1/p}
\]
and substituting the function value at the point $z_0$ we obtain
\[
-C_p (1 + \ln^p N)^{1/p} \int_{\mathbb{R}^2} |\varrho - x^2 - y^2|^{(p+1)/p} \ dx \ dy \leq \frac{1}{1 - \alpha_p \lambda} \sum_{j=1}^N (\lambda_{j,p} + c\lambda) - N\varrho
\]
with the constant $C_p = q(p + 1)^{-1/p} (C'_p)^{-1/p}$, which is further equivalent to
\[
C_p (1 + \ln^p N)^{1/p} g(\varrho)^{2(p+1)/p} \geq N\varrho - \frac{1}{1 - \alpha \lambda} \sum_{j=1}^N (\lambda_{j,p} + c\lambda)
\]
with the new constant given by $C_p' := C_p \int_{\mathbb{R}^2} |\varrho - x^2 - y^2|^{(p+1)/p} \ dx \ dy$.

In the final step, we apply Legendre transformation [ME82] to the function on the right-hand side of (3.4), $g(\varrho) := C_p (1 + \ln^p N)^{1/p} g(\varrho)^{2(p+1)/p}$. By definition we have
\[
\hat{g}(\varrho) = \sup_{\varrho \geq 0} \left( N\varrho - C_p (1 + \ln^p N)^{1/p} g(\varrho)^{2(p+1)/p} \right)
\]
and denoting the expression in the bracket as $h(\varrho)$, we check easily that it reaches its maximum at the point $\varrho_{\text{max}} = (p/(2p+1)C_p)^{1/p+1}/(1 + \ln^p N)^{1/(p+1)}$ and its value there equals
\[
\hat{g}(\varrho) = h(\varrho_{\text{max}}) = C_p \frac{N^{(2p+1)/(p+1)}(1 + \ln^p N)^{1/(p+1)}}{(1 + \ln^p N)^{1/(p+1)}}
\]
with the constant
\[
C_p := \left( \frac{p}{(2p+1)C_p'} \right)^{p/(p+1)} \frac{p + 1}{2p + 1}.
\]

Then (3.4) implies the bound
\[
\frac{1}{1 - \alpha_p \lambda} \sum_{j=1}^N (\lambda_{j,p} + c\lambda) \geq h(\varrho_{\text{max}}) = \hat{g}(\varrho),
\]
which is equivalent to the claim of the theorem. \( \square \)
Remark 3.1. While our main interest concerns sum of eigenvalues, we note that one can use the above result also to derive bounds on more general Lieb–Thirring-type expressions. Indeed, it follows that for large enough natural $N$ the spectrum $\lambda_{1,p} \leq \lambda_{2,p} \leq \cdots$ of the operator $L_p(\lambda)$ satisfies

$$\sum_{j=1}^{K} \lambda_{j,p} \geq \frac{1}{2} C_p(1 - \alpha \lambda) \frac{N^{(2p+1)/(p+1)}}{(1 + \ln^p N)^{(p+1)/p}} + 1, \quad K = 1, 2, \ldots .$$

Using this inequality for $K = N$ we infer, in particular, that

$$\lambda_{2N,p} \geq \frac{1}{2} C_p(1 - \alpha \lambda) \frac{N^{(p+1)/p}}{(1 + \ln^p N)^{(p+1)/p}} .$$

Consequently for any positive number $\sigma$ we obtain

$$\sum_{j=1}^{N} \lambda_{j,p}^{\sigma} \geq \sum_{j=2N}^{N} \lambda_{j,p}^{\sigma} \geq C_p(1 - \alpha \lambda)^{\sigma} \frac{N^{(p(\sigma+1)+1)/(p+1)}}{(1 + \ln^p N)^{\sigma/(p+1)}} ,$$

and as a result, the inequality

$$\sum_{j=1}^{N} \lambda_{j,p}^{\sigma} \geq \sum_{j=1}^{3N/2} \lambda_{j,p}^{\sigma} \geq C_p(1 - \alpha \lambda)^{\sigma} \frac{N^{(p(\sigma+1)+1)/(p+1)}}{(1 + \ln^p N)^{\sigma/(p+1)}}$$

is valid with some positive constant $\tilde{C}_p$.

3.2. Upper bounds

Next we will perform a complementary task and establish an upper bound for spectral sums of $L_p(\lambda)$, $p \geq 1$, with any subcritical $\lambda$. It will show, in particular, that in the case $\lambda = 0$ the asymptotics given by theorem 3.1 is exact up to the value of the constant.

Theorem 3.2. To any $p \geq 1$ there is a constant $\tilde{C}_p$ such that

$$\sum_{j=1}^{N} \lambda_{j,p} \leq \tilde{C}_p \frac{N^{(2p+1)/(p+1)}}{(1 + \ln^p N)^{(p+1)/p}} , \quad N = 1, 2, \ldots$$

holds for any $0 \leq \lambda < \gamma_p$.

Proof. Consider the operator $\hat{H}_p = -\Delta + Q$, where $Q(x, y) = |x|^p + |x|^p + |y|^p + 1$, in $L^2(\mathbb{R}^2)$. Its spectrum is discrete by theorem 2.1 and minimax principle since $H_p \geq L_p$, and it is obviously sufficient to establish a bound of the above type for the eigenvalues $0 \leq \beta_{1,p} \leq \beta_{2,p} \leq \cdots$ of the estimating operator $H_p$.

We shall employ Weyl asymptotics for the number of eigenvalues of below bounded differential operators in a version proved by Rozenblum [Ro74]. Let $T = -\Delta + V$ in $\mathbb{R}^m$, where the potential $V(x) \geq 1$ and tends to infinity as $|x| \to \infty$. We denote by $E(\lambda, V)$ the set $\{x \in \mathbb{R}^m : V(x) < \lambda\}$ and put $\sigma(\lambda, V) = \mes E(\lambda, V)$.

For any unit cube $D \subset \mathbb{R}^m$ we denote the mean value of the function $V$ in $D$ by $V_D$. Furthermore, given a function $f \in L^1(D)$ and $t \leq \sqrt{m}$ we define its $L_1$-modulus of continuity by the formula

$$\omega_t(f, D) := \sup_{|z| < t, z \in D} \int_{D_z} |f(x + z) - f(x)| \, dx .$$

Then, we have the following result [Ro74].
There is a continuous and monotonic function $\eta : t \in [0, \sqrt{m}] \to \mathbb{R}_+$ with $\eta(0) = 0$ and a number $\beta \in [0, \frac{1}{2})$ such that for any unit square $D$ we have

$$\omega_1(V, t, D) \leq \eta(t)^{2\beta} V_D^{1+\beta}.$$ 

Under these assumptions the asymptotic formula

$$N(\lambda, V) \sim \Gamma_m \Phi(\lambda, V)$$

holds for the operator $T = -\Delta + V$, where $N(\lambda, V)$ is the number of eigenvalues of $T$ smaller than $\lambda$, unit-ball volume $\Gamma_m = (2\sqrt{\pi})^{-m} \left( \Gamma \left( \frac{m}{2} + 1 \right) \right)^{-1}$ and

$$\Phi(\lambda, V) = \int_{\mathbb{R}^2} (\lambda - V)^{m/2} \, dx \, dy,$$

where as usual $f(x)_+ := \max(f(x), 0)$. Let us check that the assumptions are satisfied for the operator $\hat{H}_p$. As for the first one, by definition we have

$$\sigma(\lambda, Q) = \int_{[x,y]:|x|^p + |y|^p \leq \lambda - 1} dx \, dy = 4 \int_0^{(\lambda - 1)^{1/p}} \int_0^{(\lambda - x^p - 1)^{1/p}} dy \, dx$$

Hence

$$\frac{1}{2p} \lambda^{1/p} \ln \lambda \leq \sigma(\lambda, Q) \leq \frac{8}{p} \lambda^{1/p} \ln \lambda$$

holds for large enough $\lambda$ verifying the first assumption. Next we have

$$|Q(x, y) - Q(x_1, y_1)| \leq 12 \cdot 16^p (x - x_1)^2 + (y - y_1)^2 \leq 4$$

which gives the second assumption with $c = 12 \cdot 16^p + 1$ and the third one with $\beta = 0$ and $\eta(t) = 12 \cdot 16^p (12 \cdot 16^p + 1) t$ for $t \in [0, \sqrt{2}]$. Hence the eigenvalues of $\hat{H}_p$ satisfy

$$N(\lambda, Q) \sim \Gamma_2 \Phi(\lambda, Q),$$

where the second factor is equal to

$$\Phi(\lambda, Q) = \int_{\mathbb{R}^2} (\lambda - |xy|^p - |x|^p - |y|^p - 1)_+ \, dx \, dy$$

$$= 4 \int_0^{(\lambda - 1)^{1/p}} \int_0^{(\lambda - x^p - 1)^{1/p}} (\lambda - x^p y^p - x^p - y^p - 1) \, dy \, dx$$

$$= 4 \int_0^{(\lambda - 1)^{1/p}} \left( \frac{\lambda - x^p - 1}{x^p + 1} \right)^{1/p} dx$$

$$= \frac{4p}{p + 1} \int_0^{(\lambda - 1)^{1/p}} \left( \frac{\lambda - x^p - 1}{x^p + 1} \right)^{1/p} dx.$$
which can be estimated as
\[
\frac{1}{4(p+1)} \lambda^{(p+1)/p} \ln \lambda \leq \Phi(\lambda, Q) \leq \frac{8}{p+1} \lambda^{(p+1)/p} \ln \lambda,
\]
implying
\[
N(\lambda, Q) \geq \tilde{C}_2 \lambda^{(p+1)/p} \ln \lambda
\]
for large enough \(\lambda\), where \(\tilde{C}_2 = \frac{C_2^2}{8(p+1)}\). We write \(\lambda\) in the form \(\lambda = C(\lambda) \frac{N}{\ln N(\lambda, Q)} \frac{\ln N(\lambda, Q)}{p} \)
and substitute it into the last inequality obtaining
\[
N(\lambda, Q) \geq \tilde{C}_2 C(\lambda)^{(p+1)/p} N(\lambda, Q) \left[ \ln C(\lambda) + \frac{p}{p+1} \ln N(\lambda, Q) - \frac{p}{p+1} \ln \ln N(\lambda, Q) \right]
\]
for \(\lambda\) large enough. If \(C(\lambda) > 1\), we can discard the first term in the last bracket obtaining
\[
N(\lambda, Q) \geq \tilde{C}_2 C(\lambda)^{(p+1)/p} N(\lambda, Q); \]
hence,
\[
C(\lambda) \leq \left( \frac{2(p+1)}{p \tilde{C}_2} \right)^\frac{p}{p+1} + 1,
\]
which implies
\[
\lambda \leq \left( \left( \frac{2(p+1)}{p \tilde{C}_2} \right)^\frac{p}{p+1} + 1 \right)^{\frac{p}{p+1}} \frac{N(\lambda, Q)}{\ln N(\lambda, Q)}
\]
and, mutatis mutandis, the following upper bound on the spectrum of the operator \(\hat{H}_p\),
\[
\sum_{j=1}^{N(\lambda, Q)} \beta_j,p \leq \lambda N(\lambda, Q) \leq \tilde{C}_p \left( \frac{N(\lambda, Q)}{\ln N(\lambda, Q) + 1} \right)^{(2p+1)/(p+1)}
\]
with a constant \(\tilde{C}_p\) depending on \(p\) only; this yields the claim of the theorem. \(\square\)

4. Horn-shaped regions

Since our bounds are valid for any \(p \geq 1\), it is natural to ask about the limit \(p \to \infty\), which would correspond to the particle confined in a region with four hyperbolic ‘horns’, \(D = \{(x, y) \in \mathbb{R}^2 : |xy| \leq 1\}\), described by the Schrödinger operator \(H_D(\lambda) : H_D(\lambda) \psi = -\Delta \psi - \lambda (x^2 + y^2) \psi\) with a non-negative parameter \(\lambda\) and Dirichlet condition on the boundary \(\partial D\). One can prove directly an analogue to theorem 3.1 for this case under a weaker restriction on the coupling constant \(\lambda\).

**Theorem 4.1.** The spectrum of \(H_D(\lambda)\) is discrete for any \(\lambda \in [0, 1)\) and the spectral estimate
\[
\sum_{j=1}^{N} \lambda_j \geq C(1 - \lambda) \frac{N^2}{1 + \ln N}, \quad N = 1, 2, \ldots,
\]
holds true with a positive constant \(C\).
Proof. Let us check that for any function \( u \in H^1 \) satisfying the condition \( u|_{\partial D} = 0 \) we have
\[
\int_D (x^2 + y^2) u^2(x, y) \, dx \, dy \lesssim \int_D |(\nabla u) (x, y)|^2 \, dx \, dy.
\]
Using the Newton–Leibnitz theorem and Cauchy inequality we obtain
\[
\int_{D_{++}} y^2 u^2(x, y) \, dx \, dy \\
= \int_0^\infty \int_0^{1/y} y u^2(x, y) \, dx \, dy \\
= \int_0^\infty \int_0^{1/y} \left( -\int_x^{1/y} \frac{\partial u}{\partial t} (t, y) \, dt \right)^2 \, dx \, dy \\
\lesssim \int_0^\infty \int_0^{1/y} \left( \frac{\partial u}{\partial t} (t, y) \, dt \right)^2 \, dx \, dy \\
\lesssim \int_0^\infty \int_0^{1/y} \int_0^{1/y} \left( \frac{\partial u}{\partial t} (t, y) \, dt \right)^2 \, dx \, dy \lesssim \int_0^\infty \int_0^{1/y} \left( \frac{\partial u}{\partial t} (t, y) \, dt \right)^2 \, dy \, dx,
\]
where \( D_{++} = \{ (x, y) \in D : x, y \geq 0 \} \). Similarly one can prove that
\[
\int_{D_{++}} x^2 u^2(x, y) \, dx \, dy \lesssim \int_0^\infty \int_0^{1/x} \left( \frac{\partial u}{\partial t} (x, t) \right)^2 \, dx \, dt;
\]
the remaining three cases with \( x \) or \( y \) taking negative values are treated in a similar way. This proves inequality (4.1), which in turn implies
\[
H_D(\lambda) \geq -(1 - \lambda) \Delta_D,
\]
where \( \Delta_D \) is the Dirichlet Laplacian on the region \( D \). Combining the classical result of Simon \([Si83]\) with the minimax principle we find that the spectrum of \( H_D(\lambda) \) is purely discrete for any \( \lambda < 1 \). To prove the sought spectral estimate it is sufficient to check that
\[
\sum_{j=1}^{N} \beta_j \geq C \frac{N^2}{1 + \ln N}, \quad N = 1, 2, \ldots,
\]
where \( \beta_j \), \( j = 1, 2, \ldots \), are the eigenvalues of \( \Delta_D \) arranged in ascending order. The asymptotic eigenvalue distribution of the Dirichlet Laplacian \( \Delta_D \) for the region in question is well known \([JMS92]\),
\[
N(\lambda) \sim \frac{1}{\pi} \lambda \ln \lambda,
\]
By means of the known inverse asymptotic formula \([RSS91, \text{section 9}]\) we obtain for the spectrum of \( -\Delta_D \) the expression
\[
\beta_j \sim \frac{\pi j}{\ln j}
\]
as \( j \to \infty \), and this in turn yields
\[
\sum_{j=1}^{N} \beta_j \geq \sum_{j=1}^{[\frac{N}{2}]} \beta_j \geq \beta_{[\frac{N}{2}]} \geq \frac{\pi}{2} \left[ \frac{N}{2} \right]^2 \frac{1}{\ln \left[ \frac{N}{2} \right]} \geq \frac{\pi}{32} \frac{N^2}{\ln N},
\]
for all sufficiently large \( N \) which proves (4.2) with some constant \( C \), and by that the spectral estimate for the operator \( H_D(\lambda) \). \( \square \)
Remark 4.1. The negative term in the Dirichlet case equals $-\lambda r^2$ where $r = (x^2 + y^2)^{1/2}$ so the force associated with this potential looks like a centrifugal one being proportional to the radius. This brings to mind a tempting picture of a trap which can release particles if it rotates fast enough. A proper description of such a system, however, requires us to add to $-\Delta D$ the operator $\omega \cdot L_z$, where $\omega$ is the angular velocity, and we will not pursue this idea further in this paper.

5. Closing remarks

It is obvious that our results do not give a full spectral picture of the model under consideration. One is naturally interested in the character of the spectrum in the critical and supercritical cases, in the validity of inequalities for the eigenvalue-sum estimates if $\alpha^{-1} \leq \lambda < \gamma_p$, as well as in the optimal values of the constants appearing in the inequalities. This leaves a lot of room for further investigations using other methods. At this moment we limit ourselves to conjecturing that the spectrum in the critical case contains a halfline and that it covers the whole real line in the supercritical case.

Acknowledgments

We are grateful to Miloš Tater for providing figure 1, to Ari Laptev for a useful discussion and to the referees for careful reading of the manuscript. The research was supported by the Czech Ministry of Education, Youth and Sports and Czech Science Foundation within the projects LC06002 and P203/11/0701.
