Abstract

Due to economical, social and ecological reason, several studies have been done in order to obtain alternative fuel sources. In this respect, fermentation, transesterification and pyrolysis if biomass have been proposed as alternative solutions. Among these different approaches, pyrolysis seems to be a simple and efficient method fuel production. Pyrolysis, assisted by solid catalysts, has also been reported and it was recognized that the product selectivity is strongly affected by the presence and the nature of heterogenous catalysts. The catalytic pyrolysis of straight jatropha curcas oil (SJO) over nanocrystalline NiO/Al2O3 at 475 °C was studied. NiO/Al2O3 catalyst was used in pyrolysis for purpose of selectively cracking of triglyceride. Nanocrystalline NiO/Al2O3 was prepared by simple heating method with polymer solution as growth inhibitor. The liquid product (biooil) were analyzed by GC-FID and FTIR, showing the formation of carboxylic acids, paraffins, olefins, and ketone. Measured physical properties of biooil is comparable to those specified for diesel oil.

Keywords: SJO, nanocrystalline, simple heating method, catalytic pyrolysis, biooil

Abstrak

Adanya pertimbangan keekonomian, sosial, dan ekologi, menyebabkan dilakukannya penelitian guna mendapatkan sumber bahan bakar alternatif. Berkaitan dengan hal tersebut, maka reaksi-reaksi seperti permentasi, transesterifikasi dan pirolisis dari biomasa telah digunakan sebagai alternatif solusi. Di antara pendekatan-pendekatan yang berbeda tersebut, pirolisis merupakan metode yang sederhana dan efisien untuk menghasilkan bahan bakar. Pirolisis, yang dibantu dengan katalis padat, telah juga dilaporkan dan diketahui bahwa selektifitas produknya sangat dipengaruhi oleh kehadiran dan sifat dari katalis-katalis heterogen yang digunakan. Pirolisis berkatalis dari minyak jarak pagar (straight jatropha curcas oil, SJO) melalui nanokristal NiO/Al2O3 pada suhu 475 °C telah dilakukan percobaannya. Katalis NiO/Al2O3 digunakan dalam pirolisis dengan tujuan untuk menengahkahan selektif dari trigliserida. Nanokristal NiO/Al2O3 dibuat dengan menggunakan metode simple heating dengan pelarut polimer sebagai penghambat pertumbuhan. Produk cair yang dihasilkan (biooil) telah dianalisa dengan menggunakan GC-FID dan FTIR, memperlihatkan adanyanya gugus asam-asma karboksilat, parafin, olenin dan keton. Sifat fisik yang diukur dari biooil dapat diperbandingkan kesetaraannya dengan spesifikasi dari minyak solar.

Kata kunci: SJO, nanokristal, metode simple heating, pirolisis berkatalis, biooil.

1. Introduction

Nowadays, there are many ways to generate green energy. Based on the renewability of the resources, energy can be classified into 2 major categories, namely renewable energy (such as solar power, wind, water, geothermal, biomass, etc) and non-renewable energy (most resources classified in this category are fossil fuels, such as petroleum, coal, and natural gas) (Olasula et al., 2009). Fossil fuels are highly commercial in global scale, especially petroleum for which the demand steadily grows from time to time. On the contrary, the production rate of fossil fuels such as petroleum has been declining in these recent years. One of efforts to overcome this issue is through the cracking vegetable oil using heterogeneous catalyst.

In this respect, fermentation, transesterification, and pyrolysis of biomass, industrial, and domestic wastes, have been proposed as alternative solutions for the increasing energy demand and environmental awareness. Among these different approaches, pyrolysis seems to be a simple and efficient method for fuel production. The pyrolysis of different triglycerides was used for fuel supply in different countries during the First and Second World Wars. These hydrocarbons were used as raw materials for gasoline and diesel-like fuel production in a cracking system similar to the petroleum process now used. Since then several studies on vegetable oil pyrolysis as an alternative method to obtain chemicals and fuels have been reported in the literature. Pyrolysis, assisted by solid catalysts, has also been reported and it was recognized that the product selectivity is strongly affected by the presence and the nature of heterogeneous catalysts (Maher and Bressler, 2007).

In recent years, the utilization of γ-alumina catalyst was able to produce the same level of hydrocarbon as can be found in gasoline, diesel and kerosene (Wijanarko et al., 2006). Moreover, the effect from adding B₂O₃ into zeolite for decarboxilation of POME (Palm Oil Methyl Ester) produced hydrocarbon product which C range was equivalent to gasoline (Setiadi and Mailisia, 2006). However, a catalyst material in a conventional form is less effective. One of the reason is caused by low catalyst activities that unable to crack the reactants into conventional fuel fraction. Moreover, the activities of catalysts are limited by formation of cokes, and the pores of the catalyst covered by cokes formation.

Nowadays, nanomaterials have become popular option to strengthen the characteristics of catalyst. For instance, Li et al. (2008) showed that utilization of NiO as nanocatalyst for pyrolysis of biomass improved their activity and selectivity compared to that of micro NiO. As a support, Al₂O₃ can increase the performance of catalyst due to its catalytic characteristic in a cracking process (Maher and Bressler, 2007).

2. Methodology

This study was conducted in two steps namely the preparation and characterization of nanocrystalline NiO/Al₂O₃, and synthesis of diesel-like hydrocarbon over NiO/Al₂O₃ catalyst in a catalytic pyrolysis reactor.

2.1 Preparation of Nanocrystalline NiO/Al₂O₃

Nanocrystalline nickel oxide on alumina support was prepared by simple heating method adopted from Abdullah and Khairurrijal (2009). These catalysts were assigned as 5 wt% NiO/Alumina. For each catalyst, required amounts of the precursor salts, i.e., Al(NO₃)₃.9H₂O and Ni(NO₃)₂.6H₂O were dissolved in deionized water and added to the support dropwise with constant stirring followed by drying in an oven at 120 ºC overnight. Polymer solution, as continuous media, was used to avoid agglomeration of particle group of catalyst. Therefore the polymer should be remained until the end of the process. Finally the solution was heated in furnace to vaporize the PEG and to produce the final nanocrystalline NiO/Al₂O₃. Flow chart of preparation of nanocrystalline NiO/Al₂O₃ is described in Figure 1.

2.2 Catalytic Pyrolysis Experiment

The catalytic pyrolysis experiments were conducted using a self-designed 50 mL batch reactor system. Figure 2 shows a schematic diagram of the apparatus. A known amount of NiO/Al₂O₃ catalyst was charged into the reactor. Cracking reactions were carried out at 475 ºC (atmospheric pressure) with internal temperature being measured by a thermocouple. The reactor was purged with nitrogen during experiment (90 min) to remove any oxygen that might have been dissolved and present in the straight jatropha curcas oil (SJO). The gas product...
was condensed and collected. The liquid product (biooil) was collected and analyzed.

**Figure 1. Catalyst preparation flow chart**

2.3 Characterizations

The surface area, pore volume and average pore radius of the catalysts were determined by the BET (Brunauer-Emmett-Teller) method. Identification of crystalline phase and its distribution in the catalyst was performed using X-ray diffraction (XRD). Analysis of the pyrolysis products (biooil) were performed using FT-IR (Fourier Transform Infra Red) and GC-FID (Flame Ionization Gas Chromatography Detector). Physical properties of biooil (product of catalytic pyrolysis), e.g. density and viscosity, were measured as well.

3. Results and Discussions

3.1 Catalysts Characterization

BET specific surface area and pore size of the samples are listed in Table 1. It can be seen that BET surface area of the catalysts decrease with increasing temperature. Increasing temperature led to more rapid PEG vaporization and sintering of catalyst which occurred during reaction. These results correspond with those informed by Abdullah et al. (2008) and Garcia et al. (2001).

| Catalyst | Heating Temperature (°C) | Heating time (minute) | Surface area (m²/g) | Pore size (Å) |
|----------|--------------------------|-----------------------|---------------------|---------------|
| Sample 1 | 550                      | 30                    | 12.98               | 103.2         |
| Sample 2 | 600                      | 30                    | 10.21               | 133.3         |
| Sample 3 | 700                      | 30                    | 14.23               | 149.9         |
| Sample 4 | 600                      | 60                    | 8.1                 | 215.3         |
The result of Sample 3 was different with the other ones due to the differences in the heating profile as shown in Figure 3. For Sample 3 the time of heating was not kept constant, and this caused the sintering that occurred on the catalyst to be weaker than other samples. XRD characterization results are shown in Figure 4. Based on XRD diffractograms, it can be seen that NiO and Al₂O₃ crystals were formed. Table 2 shows the results of crystallite size of catalyst, where the increasing temperature and time resulted in larger crystal sizes. Higher temperature accelerated PEG vaporization which was used as growth inhibitor, while a longer heating time could provide an opportunity to crystal growth. Therefore, sintering will occur faster in formation of larger crystal. However, the different case happened on Sample 3, which was caused by the different heating profiles of Sample 1 and 2 as shown in Figure 3.
3.2 Biooil Characterization

The visual appearances of pyrolytic products (biooil) are yellow, tawny, and blackish brown as seen in Figure 5. Pyrolysis of SJO was performed with three sample catalysts which had the smaller crystal size, namely Sample 1, 2, and 3. Tables 3 and 4 show the results of density and viscosity measurements. The results of density and viscosity measurement confirmed that cracking occurred and the values showed in the range of diesel fuel. It was proved by the decreasing of those two physical properties compared with SJO ones. The use of catalysts affected in reduction of density and viscosity of biooil, rather than that without catalyst.

Crystallite size of catalysts affected the result of the physical properties of biooil products. Decreasing crystal size tended to reduce density and viscosity of biooil. This relates to the enhancement of material properties when its size became smaller. Surface area is also one of the factors of the decreasing density. Higher surface area caused jatropha oil molecules to be more reactive and gives the higher cracking effect.

| Table 2. Crystallite Size of Catalysts |
| Sample | Crystal size (nm) |
|-------|------------------|
| 1     | 156.800          |
| 2     | 174.330          |
| 3     | 153.000          |
| 4     | 191.554          |

| Table 3. Density of Biooil |
|---------------------------|
| Catalysts | \( \rho \) (gr/mL) at 25°C | Biooil | Diesel | SJO |
|------------|-------------------------------|--------|-------|-----|
| With catalyst | Without catalysts | With catalyst | Without catalysts |
| Sample 1   | 0.8581     | 0.8990 | 0.822 | 0.9107 |
| Sample 2   | 0.8397     | 0.8990 |       |       |
| Sample 3   | 0.8274     |        |       |       |

| Table 4. Viscosity of Biooil |
|-------------------------------|
| Catalysts | \( \mu \) (cp) at 25°C | Biooil | Diesel | SJO |
|------------|------------------------|--------|-------|-----|
| With catalyst | Without catalysts | With catalyst | Without catalysts |
| Sample 1   | 2.0974   | 2.1863 | 3.5   | 40.5 |
| Sample 2   | 2.1683   | 15.8598 |       |       |
| Sample 3   | 1.7500   |        |       |       |
In order to identify biooil a GC-FID analysis was carried out. Among the classes of compounds formed (Table 5), diesel-like hydrocarbon was identified. The result of GC-FID shows that cracking process was selective towards C\textsubscript{12}-C\textsubscript{18}, diesel fraction with the most high percentage as many as 54.16%.

Table 5. GC-FID results

| Carbon chain | Yield (% Wt.) | Product       |
|--------------|---------------|---------------|
| C\textsubscript{1}-C\textsubscript{5} | 0.05          | Gas           |
| C\textsubscript{6}-C\textsubscript{11} | 16.25         | Gasoline      |
| C\textsubscript{12}-C\textsubscript{12} | 8.91          | Kerosene      |
| C\textsubscript{12}-C\textsubscript{18} | 54.16         | Diesel        |
| C\textsubscript{18}-C\textsubscript{25} | 33.48         | Lubricant     |
| C\textsubscript{21}-C\textsubscript{27} | 20.16         | Fuel oil      |

Figure 6 shows FTIR spectra obtained for SJO, biooil and diesel oil. Each spectrum was normalized by the intensity of the absorption band centered at 2930 cm\textsuperscript{-1} (the strongest band). Characteristic vibrational modes are observed at 3080 cm\textsuperscript{-1} (CH stretching, olefinic), 2850–2990 cm\textsuperscript{-1} (CH stretching, aliphatic), 1710 cm\textsuperscript{-1} (C=O stretching), and 1642 cm\textsuperscript{-1} (C=C stretching, olefinic). The products of SJO cracking present some absorption features that are not observed in the other two oil cracking products, e.g. the absorption at 1700-1720 cm\textsuperscript{-1} that is characteristic of keton. It is also observed for SJO and biooil. The absorptions at 1285 and 1240 cm\textsuperscript{-1}, indicating the presence of carboxylic acids. It is worth mentioning that no vibrational feature, characteristic of aromatic compounds, was observed in the FTIR spectra, which is in good agreement with what was observed in the GC-FID analysis.

4. Conclusions

In this research, NiO/Al₂O₃ catalysts were prepared by simple heating method with polymer solution as a growth inhibitor. Characterization of catalysts have shown that the smallest crystal catalyst size is 153 nm which prepared at 700 °C when the heating temperature was not keep constant. Catalytic pyrolysis of SJO over NiO/Al₂O₃ was carried out in batch reactor. The experimental conditions were 475 °C for average reaction temperature and 90 minutes for residence time. These condition led to dominant yield of 54.16% of diesel fraction (C₁₂-C₁₈). Measured physical properties of biooil is comparable to those specified for diesel oil, i.e. the densities of biooil were in the range of diesel fuel specifications, but the viscosities of biooil were still lower than criteria of diesel fuel specifications.
