SPECIAL ELEMENTS OF THE LATTICE
OF EPIGROUP VARIETIES

V. YU. SHAPRYNSKIĬ, D. V. SKOKOV, AND B. M. VERNIKOV

Abstract. We study special elements of five types (namely, neutral, co-
standard, codistributive, modular and upper-modular elements) in the lat-
tice $\textbf{Epi}$ of all epigroup varieties. Neutral and costandard elements are
completely determined. It turns out that the properties of being elements
of these two types in $\textbf{Epi}$ are equivalent, and only four epigroup varieties
have each of these properties. We find a strong necessary condition for mod-
ular elements that completely reduces the problem of description of corre-
sponding varieties to nilvarieties satisfying identities of some special type.
Modular elements are completely classified within the class of commutative
varieties, while codistributive and upper-modular elements are completely
determined within the wider class of strongly permutative varieties.

1. Introduction and summary

1.1. Semigroup pre-history. The main object we examine in this article is
the lattice of all epigroup varieties. But our considerations are motivated by
some earlier investigations of the lattice of semigroup varieties and closely re-
lated with these investigations. To make clearer a context and motivations of
our considerations, we start with a brief explanation of the ‘semigroup pre-
history’ of the present work.

One of the main branches of the theory of semigroup varieties is an examina-
tion of lattices of semigroup varieties (see the survey [16]). If $\mathcal{V}$ is a variety then
$L(\mathcal{V})$ stands for the subvariety lattice of $\mathcal{V}$ under the natural order (the class-
theoretical inclusion). The lattice operations in $L(\mathcal{V})$ are the (class-theoretical)
intersection denoted by $\mathcal{X} \wedge \mathcal{Y}$ and the join $\mathcal{X} \lor \mathcal{Y}$, i.e., the least subvariety of
$\mathcal{V}$ containing both $\mathcal{X}$ and $\mathcal{Y}$.

There are a number of articles devoted to an examination of identities (first
of all, the distributive, modular or Arguesian laws) and some related restric-
tions (such as semimodularity or semidistributivity) in lattices of semigroup
varieties, and many considerable results are obtained here. In particular, semi-
group varieties with modular, Arguesian or semimodular subvariety lattice were

Federation (project 5161.2014.1) and by Russian Foundation for Basic Research (grant 14-01-
00524).
completely classified and deep results concerning semigroup varieties with distributive subvariety lattices (related to a description of such varieties modulo group ones) were obtained. An overview of all these results may be found in [16, Section 11].

The results mentioned above specify, so to say, ‘globally’ modular or distributive parts of the lattice of semigroup varieties. The following natural step is to examine varieties that guarantee modularity or distributivity, so to say, in their ‘neighborhood’. Saying so, we take in mind special elements in the lattice of semigroup varieties. There are many types of special elements that are considered in lattice theory. Recall definitions of some of them. An element $x$ of a lattice $(L; \lor, \land)$ is called

- **neutral** if $(x \lor y) \land (y \lor z) \land (z \lor x) = (x \land y) \lor (y \land z) \lor (z \land x)$ for all $y, z \in L$;
- **standard** if $(x \lor y) \land z = (x \land z) \lor (y \land z)$ for all $y, z \in L$;
- **distributive** if $x \lor (y \land z) = (x \lor y) \land (x \lor z)$ for all $y, z \in L$;
- **modular** if $(x \lor y) \land z = (x \land z) \lor y$ for all $y, z \in L$ with $y \leq z$;
- **upper-modular** if $(z \lor y) \land x = (z \land x) \lor y$ for all $y, z \in L$ with $y \leq x$.

Costandard, codistributive and lower-modular elements are defined dually to standard, distributive and upper-modular ones.

Note that special elements play an essential role in the abstract lattice theory. For instance, if an element $x$ of a lattice $L$ is neutral then $L$ is decomposed into a subdirect product of its intervals $(x] = \{y \in L \mid y \leq x\}$ and $[x) = \{y \in L \mid x \leq y\}$ (see [2, Theorem 254 on p. 226]). Thus, the knowledge of what elements of a lattice are neutral, gives the important information on a structure of the lattice as a whole.

All types of elements mentioned above are intensively and successfully studied with respect to the lattice SEM of all semigroup varieties. For brevity, a semigroup variety that is a neutral element of the lattice SEM is called a neutral in SEM variety. Analogous convention is applied for all other types of special elements. Results about special elements in SEM are overviewed in the recent survey [25]. In particular,

- neutral in SEM varieties were completely determined in [31];
- it is proved that a semigroup variety is costandard in SEM if and only if it is neutral in SEM [24]; thus, in view of the previous result, costandard in SEM varieties are completely classified;
- strong necessary conditions for modular in SEM varieties were discovered in [6] and [19] (these results are reproved in a simpler way in [11]);
- commutative modular in SEM varieties were completely determined in [19];
- commutative upper-modular in SEM varieties were completely classified in [22]; it is noted in [21] that this result may be expanded on wider class of strongly permutative varieties without any change (a definition of strongly permutative varieties see in Subsection 1.2 below);
- strongly permutative codistributive varieties were completely described in [24].
1.2. **Epigroups.** A considerable attention in the semigroup theory is devoted to semigroups equipped by an additional unary operation. Such algebras are said to be *unary semigroups*. As concrete types of unary semigroups, we mention completely regular semigroups (see [8]), inverse semigroups (see [7]), semigroups with involution etc.

One more natural type of unary semigroups is epigroups. A semigroup $S$ is called an *epigroup* if, for any element $x$ of $S$, there is a natural $n$ such that $x^n$ is a *group element* (this means that $x^n$ lies in some subgroup of $S$). Extensive information about epigroups may be found in the fundamental work [14] by L. N. Shevrin and the survey [15] by the same author. The class of epigroups is very wide. In particular, it includes all periodic semigroups (because some power of each element in such a semigroup lies in some its finite cyclic subgroup) and all completely regular semigroups (in which all elements are group ones).

The unary operation on an epigroup is defined by the following way. If $S$ is an epigroup and $x \in S$ then some power of $x$ lies in a maximal subgroup of $S$. We denote this subgroup by $G_x$. The unit element of $G_x$ is denoted by $x_\omega$. It is well known (see [14], for instance) that the element $x_\omega$ is well defined and $xx_\omega = x_\omega x \in G_x$. We denote the element inverse to $xx_\omega$ in $G_x$ by $\overline{x}$. The map $x \mapsto \overline{x}$ is just the mentioned unary operation on an epigroup $S$.

An overview of first results obtained here may be found in [16, Section 2]. If $S$ is a completely regular semigroup (i.e., the union of groups) and $x \in S$ then $\overline{x}$ is the element inverse to $x$ in the maximal subgroup containing $x$. Thus, the operation of pseudoinversion on a completely regular semigroup coincides with the unary operation traditionally considered on completely regular semigroups. We see that varieties of completely regular semigroups (considered as unary semigroups) are varieties of epigroups in the sense defined above. Further, it is well known and may be easily checked that in every periodic epigroup the operation of pseudoinversion may be expressed in terms of multiplication (see [14], for instance). This means that periodic varieties of epigroups may be identified with periodic varieties of semigroups.

It seems to be very natural to examine all restrictions on semigroup varieties mentioned in Subsection 1.1 for epigroup varieties. This is realized in [28] for identities and related restrictions to subvariety lattice. In particular, epigroup varieties with modular, Arguesian or semimodular subvariety lattice are completely classified and epigroup analogs of results concerning semigroup varieties with distributive subvariety lattice are obtained there. In the present article, we start with an examination of special elements in the lattice $\textbf{Epi}$ of all epigroup varieties. We consider here neutral, costandard, codistributive, modular and upper-modular elements in $\textbf{Epi}$. For brevity, we call an epigroup variety *neutral* if it is a neutral element of the lattice $\textbf{Epi}$. Analogous convention will be applied for all other types of special elements. Our main results give:
• a complete description of neutral and costandard varieties (the properties of being varieties of these two types turn out to be equivalent);
• a strong necessary condition for modular varieties;
• a description of commutative modular varieties, strongly permutative codistributive varieties and strongly permutative upper-modular varieties.

We denote by $T$, $SL$ and $ZM$ the trivial variety, the variety of all semilattices and the variety of all semigroups with zero multiplication respectively. The first main result of the article is the following

**Theorem 1.1.** For an epigroup variety $V$, the following are equivalent:

a) $V$ is a neutral element of the lattice $Epi$;

b) $V$ is a costandard element of the lattice $Epi$;

c) $V$ is simultaneously a modular, lower-modular and upper-modular element of the lattice $Epi$;

d) $V$ coincides with one of the varieties $T$, $SL$, $ZM$ or $SL \lor ZM$.

Thus, there are only a few neutral elements in the lattice $Epi$. In contrast, we note that the lattice of completely regular semigroup varieties contains infinitely many neutral elements including all band varieties, the varieties of all groups, all completely simple semigroups, all orthodox semigroups and some other (this readily follows from [17, Corollary 2.9]).

Recall that an identity of the form $x_1 x_2 \cdots x_n = x_1 \pi x_2 \pi \cdots x_n \pi$

where $\pi$ is a non-trivial permutation on the set $\{1, 2, \ldots, n\}$ is called permutative; if $1 \pi \neq 1$ and $n \pi \neq n$ then this identity is said to be strongly permutative. A semigroup or a variety that satisfies [strongly] permutative identity also is called [strongly] permutative. If $n$ is a natural number then a variety $X$ is called a variety of degree $n$ if all nil-semigroups in $X$ are nilpotent of degree $\leq n$ and $n$ is the least number with such a property. The second main result of the article is the following

**Theorem 1.2.** For a strongly permutative epigroup variety $V$, the following are equivalent:

a) $V$ is a codistributive element of the lattice $Epi$;

b) $V$ is a variety of degree $\leq 2$;

c) $V = \mathcal{G} \lor X$ where $\mathcal{G}$ is an abelian group variety, while $X$ is one of the varieties $T$, $SL$, $ZM$ or $SL \lor ZM$.

To formulate the third result, we need some definitions. We follow the agreement that an adjective indicating a property shared by all semigroups of a given variety is applied to the variety itself; the expressions like ‘completely regular variety’, ‘periodic variety’, ‘nilvariety’, etc. are understood in this sense. A pair of identities $wx = xw = w$ where the letter $x$ does not occur in the word $w$ is usually written as the symbolic identity $w = 0$. This notation is justified because a semigroup with such identities has a zero element and all values of the word $w$ in this semigroup are equal to zero. We will refer to the expression $w = 0$ as to a single identity and call such identities 0-reduced. We call an
identity \( u = v \) substitutive if \( u \) and \( v \) are plain semigroup words (i.e., they do not contain the operation of pseudoinversion), these words depend on the same letters and \( v \) may be obtained from \( u \) by renaming of letters. The third main result of the article is the following

**Theorem 1.3.** If an epigroup variety \( \mathcal{V} \) is a modular element of the lattice \( \mathcal{Epi} \) then \( \mathcal{V} = \mathcal{M} \lor \mathcal{N} \) where \( \mathcal{M} \) is one of the varieties \( \mathcal{T} \) or \( \mathcal{SL} \) and \( \mathcal{N} \) is a nilvariety given by 0-reduced and substitutive identities only.

It is easy to see that this theorem completely reduces the problem of description of modular varieties to nilvarieties defined by 0-reduced and substitutive identities only (see Corollary 3.3 below).

The fourth result of the article is the following

**Theorem 1.4.** A commutative epigroup variety \( \mathcal{V} \) is a modular element of the lattice \( \mathcal{Epi} \) if and only if \( \mathcal{V} = \mathcal{M} \lor \mathcal{N} \) where \( \mathcal{M} \) is one of the varieties \( \mathcal{T} \) or \( \mathcal{SL} \) and \( \mathcal{N} \) is a nilvariety that satisfies the commutative law and the identity

\[
x^2 y = 0.
\]

Let \( \Sigma \) be an identity system written in the language of one associative binary operation and one unary operation. The class of all epigroups that satisfy \( \Sigma \) (where the unary operation is treated as pseudoinversion) is denoted by \( K_\Sigma \). The class \( K_\Sigma \) is not obliged to be a variety because it maybe not closed under taking of (infinite) direct product (see [15, Subsection 2.3], for instance). Note that identity systems \( \Sigma \) with the property that \( K_\Sigma \) is a variety are completely determined in [4, Proposition 2.16]. If \( K_\Sigma \) is a variety then we use for this variety the standard notation \( \text{var } \Sigma \). It is evident that if the class \( K_\Sigma \) consists of periodic epigroups then it is a periodic semigroup variety and therefore, is an epigroup variety. Whence, the notation \( \text{var } \Sigma \) is correct in this case. Put

\[
C_m = \text{var } \{x^m = x^{m+1}, \ xy = yx\}
\]

for arbitrary natural \( m \). In particular, \( C_1 = \mathcal{SL} \). It will be convenient for us also to assume that \( C_0 = \mathcal{T} \). The fifth main result of the article is the following

**Theorem 1.5.** A strongly permutative epigroup variety \( \mathcal{V} \) is an upper-modular element of the lattice \( \mathcal{Epi} \) if and only if one of the following holds:

(i) \( \mathcal{V} = \mathcal{M} \lor \mathcal{N} \) where \( \mathcal{M} \) is one of the varieties \( \mathcal{T} \) or \( \mathcal{SL} \), and \( \mathcal{N} \) is a nilvariety satisfying the commutative law and the identity

\[
x^2 y = xy^2;
\]

(ii) \( \mathcal{V} = \mathcal{G} \lor C_m \lor \mathcal{N} \) where \( \mathcal{G} \) is an abelian group variety, \( 0 \leq m \leq 2 \) and \( \mathcal{N} \) satisfies the commutative law and the identity \( (1) \).

Theorems 1.4 and 1.5 evidently imply

**Corollary 1.6.** If a commutative epigroup variety is a modular element of the lattice \( \mathcal{Epi} \) then it is an upper-modular element of this lattice.

The article is structured as follows. It consists of eight sections. In Section 2 we collect definitions, notation and auxiliary results used in what follows. In Section 3 we verify two special cases of Theorem 1.1, namely the claims that the
The varieties $\mathcal{SL}$ and $\mathcal{ZM}$ are neutral. These facts are used in the proofs of several other theorems. After that we prove Theorem 1.5 in Section 4, Theorem 1.2 in Section 5, Theorems 1.3 and 1.4 in Section 6, and Theorem 1.1 in Section 7. Finally, in Section 8 we formulate several open questions.

2. Preliminaries

2.1. Some properties of the operation of pseudoinversion. The following four lemmas are well known and may be easily checked.

**Lemma 2.1.** The identity
\[
\overline{x} = x \overline{x}^2
\]
holds in every epigroup.

**Lemma 2.2.** The identity
\[
x = \overline{x}
\]
holds in an epigroup $S$ if and only if $S$ is completely regular.

It is well known (see [14,15], for instance) that if $S$ is an epigroup and $x \in S$ then $x \overline{x} = x^2$. This permits to write in epigroup identities expressions of the form $u^2$ rather than $u \overline{u}$, for brevity.

**Lemma 2.3.** If an epigroup variety $V$ satisfies the identity $x^m = x^{m+1}$ then the identities $x^2 = \overline{x} = \overline{x}^2 = x^m$ hold in $V$.

**Lemma 2.4.** The identity
\[
x = 0
\]
holds in an epigroup $S$ if and only if $S$ is a nil-semigroup.

2.2. Identities of certain varieties. We denote by $F$ the free unary semigroup over a countably infinite alphabet (with the operations $\cdot$ and $\overline{\cdot}$). Elements of $F$ are called words. If $w \in F$ then we denote by $c(w)$ the set of all letters occurring in $w$ and by $t(w)$ the last letter of $w$. A letter is called simple [multiple] in a word $w$ if it occurs in $w$ ones [at least twice]. We call a word a semigroup word if it does not include the operation of pseudoinversion. An identity is called a semigroup identity if both its parts are semigroup words.

Put
\[
\mathcal{P} = \text{var}\{xy = x^2y, x^2y^2 = y^2x^2\} \quad \text{and} \quad \overline{\mathcal{P}} = \text{var}\{xy = xy^2, x^2y^2 = y^2x^2\}.
\]

The first two claims of the following lemma are well-known and may be easily verified, the third one was proved in [1, Lemma 7].

**Lemma 2.5.** A non-trivial semigroup identity $v = w$ holds:

(i) in the variety $\mathcal{SL}$ if and only if $c(v) = c(w)$;

(ii) in the variety $\mathcal{C}_2$ if and only if $c(v) = c(w)$ and every letter from $c(v)$ is either simple both in $v$ and $w$ or multiple both in $v$ and $w$;

(iii) in the variety $\mathcal{P}$ if and only if $c(v) = c(w)$ and either the letters $t(v)$ and $t(w)$ are multiple in $v$ and $w$ respectively or $t(v) \equiv t(w)$ and the letter $t(v)$ is simple both in $v$ and $w$.\[\square\]
If \( w \) is a semigroup word then \( \ell(w) \) stands for the length of \( w \); otherwise, we put \( \ell(w) = \infty \). We need the following three remarks about identities of nil-semigroups.

**Lemma 2.6.** Let \( \mathcal{V} \) be a nilvariety.

1. If the variety \( \mathcal{V} \) satisfies an identity \( u = v \) with \( c(u) \neq c(v) \) then \( \mathcal{V} \) satisfies also the identity \( u = 0 \).
2. If the variety \( \mathcal{V} \) satisfies an identity of the form \( u = vwv \) where the word \( vw \) is non-empty then \( \mathcal{V} \) satisfies also the identity \( u = 0 \).
3. If the variety \( \mathcal{V} \) satisfies an identity of the form \( x_1x_2\cdots x_n = v \) and \( \ell(v) \neq n \) then \( \mathcal{V} \) satisfies also the identity \( x_1x_2\cdots x_n = 0 \).

**Proof.** The claims (i) and (ii) are well known and easily verified.

(iii) If \( v \) is a non-semigroup word, it suffices to refer to Lemma 2.4. Let now \( v \) be a semigroup word. If \( \ell(v) < n \) then \( c(v) \neq \{x_1, x_2, \ldots, x_n\} \), and the desired conclusion follows from the claim (i). Finally, if \( \ell(v) > n \) then the claim we prove readily follows from [9, Lemma 1]. \( \square \)

### 2.3. Decomposition of commutative varieties into the join of subvarieties.

As usual, we denote by \( \text{Gr} S \) the set of all group elements of an epigroup \( S \). For an arbitrary epigroup variety \( \mathcal{X} \), we put \( \text{Gr}(\mathcal{X}) = \mathcal{X} \cap \mathcal{G} \mathcal{R} \) where \( \mathcal{G} \mathcal{R} \) is the variety of all groups. The variety generated by an epigroup \( S \) is denoted by \( \var{S} \). Put

\[
\mathcal{L} \mathcal{Z} = \var{xy = x} \quad \text{and} \quad \mathcal{R} \mathcal{Z} = \var{xy = y}.
\]

The following two facts play an important role in the proof of Theorem 1.5. ‘Semigroup prototypes’ of Proposition 2.7 and Lemma 2.8 were given in [29, Proposition 1] and [5] respectively.

**Proposition 2.7.** If \( \mathcal{V} \) is an epigroup variety and \( \mathcal{V} \) does not contain the varieties \( \mathcal{L} \mathcal{Z}, \mathcal{R} \mathcal{Z}, \mathcal{P} \) and \( \mathcal{P}^\omega \) then \( \mathcal{V} = \mathcal{M} \lor \mathcal{N} \) where \( \mathcal{M} \) is a variety generated by a monoid, and \( \mathcal{N} \) is a nilvariety.

**Proof.** It is verified in [29, Lemma 2] that if a semigroup variety does not contain the varieties \( \mathcal{L} \mathcal{Z}, \mathcal{R} \mathcal{Z}, \mathcal{P} \) and \( \mathcal{P}^\omega \) then \( \mathcal{V} \) satisfies the quasiidentity

\[
e^2 = e \rightarrow ex = xe.
\]

Repeating literally the proof of this claim (with using a term ‘subepigroup’ rather than ‘subsemigroup’), one can establish that the similar claim is true for epigroup varieties. Thus, \( \mathcal{V} \) satisfies the quasiidentity (6). The rest of the proof is quite similar to the proof of Proposition 1 in [29].

Let \( S \) be an epigroup that generates the variety \( \mathcal{V} \), \( x \in S \) and \( E \) the set of all idempotents from \( S \). In view of (6), \( ES \) is an ideal in \( S \). By the definition of an epigroup, there is a natural \( n \) such that \( x^n \in \text{Gr} S \). Then \( x^n = x^\omega x^n \) and \( x^\omega \in E \). We see that \( x^n \in ES \). Therefore, the Rees quotient semigroup \( S/ES \) is a nil-semigroup and therefore, is an epigroup. The natural homomorphism \( \rho \) from \( S \) onto \( S/ES \) separates elements from \( S \setminus ES \).

Let now \( e \in E \). In view of (6), we have that \( eS \) is a subsemigroup in \( S \). By Lemma 2.1 the epigroup \( S \) satisfies the identity (3). Hence the equality \( e \overline{x} = ex(\overline{e}x)^2 \) holds. We have verified that, for any \( e \in E \), the set \( eS \) is
a subepigroup in $S$. Put $S^* = \prod_{e \in E} eS$. Then $S^*$ is an epigroup with unit $(\ldots, e, \ldots)_{e \in E}$. It follows from (6) that the map $\varepsilon$ from $S$ into $S^*$ given by the rule $\varepsilon(x) = (\ldots, ex, \ldots)_{e \in E}$ is a semigroup homomorphism. As is well known (see [14, 15], for instance), an arbitrary semigroup homomorphism $\xi$ from an epigroup $S_1$ into an epigroup $S_2$ is also an epigroup homomorphism (i.e., $\xi(a) = \xi(a)$ for any $a \in S_1$). Therefore, $\varepsilon$ is an epigroup homomorphism from $S$ into $S^*$. One can verify that $\varepsilon$ separates elements of $E S$. Let $e, f \in E$, $x, y \in S$ and $\varepsilon(ex) = \varepsilon(fy)$. Then $e \cdot ex = e \cdot fy$ and $f \cdot ex = f \cdot fy$. Since $e, f \in E$, we have

(7)  
$$ex = efy \quad \text{and} \quad fex = fy.$$  

Therefore,

$$ex = efy \quad \text{by (7)}$$
$$= efex \quad \text{by (7)}$$
$$= fex \quad \text{by (6)}$$
$$= feex \quad \text{because } e \in E$$
$$= fex \quad \text{by (7)}.$$

We see that $ex = fy$ whenever $\varepsilon(ex) = \varepsilon(fy)$. This means that $\varepsilon$ separates elements of $ES$.

Thus, $\varepsilon$ and $\rho$ are homomorphisms from $S$ into $S^*$ and $S/ES$ respectively, and the intersection of kernels of these homomorphisms is trivial. Therefore, the epigroup $S$ is decomposable into a subdirect product of the epigroups $S^*$ and $S/ES$, whence $V \subseteq M \lor N$ where $M = \text{var } S^*$ is a variety generated by a monoid and $N = \text{var } (S/ES)$ is a nilvariety. On the other hand $S^*, S/ES \in V$, whence $M \lor N \subseteq V$. We have proved that $V = M \lor N$. \hfill $\square$

Recall that an epigroup is called combinatorial if all its subgroups are trivial.

**Lemma 2.8.** If an epigroup variety $M$ is generated by a commutative epigroup with unit then $M = C \lor C_m$ for some abelian group variety $C$ and some $m \geq 0$.

**Proof.** It is well known that the variety of all abelian groups is the least non-periodic epigroup variety. This variety evidently contains the infinite cyclic group. Further, for each natural $m$, let $G_m$ denote the cyclic group of order $m$. It is evident that if $M$ is periodic then the set \{ $m \in \mathbb{N} \mid G_m \in M$ \} has the greatest element. We denote by $G$ the infinite cyclic group whenever the variety $M$ is non-periodic, and the finite cyclic group of the greatest order among all cyclic groups in $M$ otherwise. In both the cases $G \in M$. Further, let $D_m$ be the finite cyclic combinatorial epigroup of order $m$ and $d_m$ is a generator of $D_m$. Put $X = \{ m \in \mathbb{N} \mid D_m \in M \}$. If the set $X$ has not the greatest element then the semigroup $\prod_{m \in X} D_m$ is not an epigroup since, for example, no power of the element $(\ldots, d_m, \ldots)_{m \in X}$ belongs to a subgroup. Therefore, the set of numbers $X$ contains the greatest number. We denote this number by $n$. Repeating literally arguments from the proof of Theorem 1 in [5], we have that every epigroup from $M$ is a homomorphic image of some subepigroup of the
epigroup $G \times D_n$. Therefore, $\mathcal{M} = \mathcal{G} \vee \mathcal{D}$ where $\mathcal{G} = \text{var } G$ and $\mathcal{D} = \text{var } D_n$. Clearly, $\mathcal{G}$ is a variety of abelian groups. The variety $\mathcal{D}$ is generated by a finite epigroup, whence it may be considered as a semigroup variety. It is well known and may be easily verified that $(m + 1)$-element combinatorial cyclic monoid generates the variety $\mathcal{C}_m$. Therefore, $\mathcal{D} = \mathcal{C}_m$ for some $m \geq 0$. □

It is evident that a strongly permutative variety does not contain the varieties $\mathcal{LZ}$, $\mathcal{RZ}$, $\mathcal{P}$ and $\overline{\mathcal{P}}$. Besides that, every monoid satisfying a permutative identity is commutative. Thus, we have the following corollary of Proposition 2.7 and Lemma 2.8.

**Corollary 2.9.** If $V$ is a strongly permutative epigroup variety then $V = \mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N}$ where $\mathcal{G}$ is an abelian group variety, $m \geq 0$ and $\mathcal{N}$ is a nilvariety. □

### 2.4. A direct decomposition of one varietal lattice

We denote by $\mathcal{AG}$ the variety of all abelian groups. Put $H = \text{var } \{x^2y = yx^2 = xyx = 0\}$.

The aim of this subsection is to prove the following

**Proposition 2.10.** The lattice $L(\mathcal{AG} \vee \mathcal{C}_2 \vee H)$ is isomorphic to the direct product of the lattices $L(\mathcal{AG})$ and $L(\mathcal{C}_2 \vee H)$.

**Proof.** We need the following auxiliary statement.

**Lemma 2.11.** If $X \subseteq \mathcal{AG} \vee \mathcal{C}_2 \vee H$ then $X = \mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N}$ where $\mathcal{G}$ is some abelian group variety, $0 \leq m \leq 2$ and $\mathcal{N}$ is a nilvariety.

**Proof.** Being a subvariety of the variety $\mathcal{AG} \vee \mathcal{C}_2 \vee H$, the variety $X$ satisfies the identity $x^2y = yx^2$. It is evident that this identity fails in the varieties $\mathcal{LZ}$ and $\mathcal{RZ}$. Further, Lemma 2.5(iii) and the dual statement imply that this identity is false in the varieties $\mathcal{P}$ and $\overline{\mathcal{P}}$ as well. Therefore, none of the four mentioned varieties is contained in $X$. Besides that, the variety $\mathcal{AG} \vee \mathcal{C}_2 \vee H$ (and therefore, $X$) satisfies the identity $x^2yz = x^2zy$. Substituting 1 for $x$, we have that all monoids in $X$ are commutative. Proposition 2.7 and Lemma 2.8 imply now that $X = \mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N}$ for some abelian group variety $\mathcal{G}$, some $m \geq 0$ and some nilvariety $\mathcal{N}$. It is evident that $\mathcal{G} \subseteq \mathcal{AG}$. Lemmas 2.2, 2.3 and 2.4 imply that $\mathcal{AG}, \mathcal{C}_m$ and $\mathcal{H}$ satisfy the identities (4), $x^m = \overline{\mathcal{P}}^2y$ and (5) respectively. Therefore, the identity $x^2y = \overline{\mathcal{P}}^2y$ holds in the variety $\mathcal{AG} \vee \mathcal{C}_2 \vee H$. But this identity is false in the variety $\mathcal{C}_m$ with $m > 2$. Hence $m \leq 2$. This implies that the variety $\mathcal{AG} \vee \mathcal{C}_m \vee H$ satisfies the identities $x^2y = yx^2 = \overline{\mathcal{P}}^2y$ and $xyx = xy\overline{\mathcal{P}}$. Since $\mathcal{N} \subseteq X \subseteq \mathcal{AG} \vee \mathcal{C}_2 \vee H$, Lemma 2.4 implies that the variety $\mathcal{N}$ satisfies the identities $x^2y = xyx = yx^2 = 0$, whence $\mathcal{N} \subseteq H$. □

Now we start with the direct proof of Proposition 2.10. Let $V \subseteq \mathcal{AG} \vee \mathcal{C}_2 \vee H$. In view of Lemma 2.11, $V = \mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N}$ for some abelian group variety $\mathcal{G}$, some $0 \leq m \leq 2$ and some variety $\mathcal{N}$ with $\mathcal{N} \subseteq H$. Put $U = \mathcal{C}_m \vee \mathcal{N}$. We have that $V = \mathcal{G} \vee U$ where $\mathcal{G} \subseteq \mathcal{AG}$ and $U \subseteq \mathcal{C}_2 \vee H$. It remains to establish that this decomposition of the variety $V$ into the join of some subvariety of the variety $\mathcal{AG}$ and some subvariety of the variety $\mathcal{C}_2 \vee H$ is unique.
Let \( \mathcal{V} = \mathcal{G}' \vee \mathcal{U}' \) where \( \mathcal{G}' \subseteq \mathcal{A}\mathcal{G} \) and \( \mathcal{U}' \subseteq \mathcal{C}_2 \vee \mathcal{H} \). We need to verify that \( \mathcal{G} = \mathcal{G}' \) and \( \mathcal{U} = \mathcal{U}' \). Let us set \( u = v \) be an arbitrary identity satisfied by \( \mathcal{G} \). The variety \( \mathcal{U} \) satisfies the identity \( x^3 = x^4 \). Then the identity \( u^4 v^3 = u^3 v^4 \) holds in the variety \( \mathcal{G} \vee \mathcal{U} \). Let us cancel this identity on \( u^3 \) from the left and on \( v^3 \) from the right, thus concluding that \( u = v \) holds in \( \text{Gr} (\mathcal{G} \vee \mathcal{U}) \). Therefore, \( \text{Gr} (\mathcal{G} \vee \mathcal{U}) \subseteq \mathcal{G} \). The opposite inclusion is evident. Thus, \( \text{Gr} (\mathcal{G} \vee \mathcal{U}) = \mathcal{G} \).

Analogously, \( \text{Gr} (\mathcal{G}' \vee \mathcal{U}') = \mathcal{G}' \).

It remains to check that \( \mathcal{G} = \mathcal{G}' \) and \( \mathcal{U} = \mathcal{U}' \). Recall that \( \mathcal{U} = \mathcal{C}_m \vee \mathcal{N} \) where \( 0 \leq m \leq 2 \) and \( \mathcal{N} \subseteq \mathcal{H} \), while \( \mathcal{U}' \subseteq \mathcal{C}_2 \vee \mathcal{H} \). It is evident that the variety \( \mathcal{C}_2 \vee \mathcal{H} \) (and therefore, \( \mathcal{U}' \) is combinatorial. Therefore, Lemma 2.11 implies that \( \mathcal{U}' = \mathcal{C}_k \vee \mathcal{N}' \) for some \( 0 \leq k \leq 2 \) and some variety \( \mathcal{N}' \) with \( \mathcal{N}' \subseteq \mathcal{H} \).

Suppose that \( m \neq k \). We may assume without any loss that \( m < k \), i.e., either \( m = 0, 1 \leq k \leq 2 \) or \( m = 1, k = 2 \). Suppose at first that \( m = 0 \) and \( 1 \leq k \leq 2 \). It is evident that any group satisfies the identity \( x^m = y^m \). Lemma 2.4 implies that this identity holds in \( \mathcal{N} \) and therefore, in \( \mathcal{V} = \mathcal{G} \vee T \vee \mathcal{N} = \mathcal{G} \vee \mathcal{N} \). But Lemma 2.5(ii) implies that this identity fails in the variety \( \mathcal{S}\mathcal{L} \). However, this is impossible because \( \mathcal{S}\mathcal{L} \subseteq \mathcal{G}' \vee \mathcal{C}_k \vee \mathcal{N}' = \mathcal{V} \). Suppose now that \( m = 1 \) and \( k = 2 \). Then Lemmas 2.2, 2.3 and 2.4 imply that the identity \( x^2 y = x^2 y^x \) holds in the variety \( \mathcal{V} = \mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N} = \mathcal{G} \vee \mathcal{S}\mathcal{L} \vee \mathcal{N} \). But this identity is false in the variety \( \mathcal{C}_2 \) (and therefore, in \( \mathcal{G}' \vee \mathcal{C}_k \vee \mathcal{N}' = \mathcal{V} \)) by Lemmas 2.3 and 2.5(ii). A contradiction shows that \( m = k \).

Note that if \( \mathcal{X} \) is an arbitrary epigroup variety then the class of all epigroups in \( \mathcal{X} \) satisfying the identity (5) is the greatest nilsubvariety of \( \mathcal{X} \). We denote this subvariety by \( \text{Nil}(\mathcal{X}) \). Put \( \mathcal{N} = \text{Nil}(\mathcal{U}) \) and \( \mathcal{N}' = \text{Nil}(\mathcal{U}') \). It suffices to verify that \( \mathcal{N} = \mathcal{N}' \) because

\[
\mathcal{U} = \mathcal{C}_m \vee \mathcal{N} = \mathcal{C}_m \vee \mathcal{N} = \mathcal{C}_k \vee \mathcal{N}' = \mathcal{C}_k \vee \mathcal{N}' = \mathcal{U}'
\]

in this case. Suppose that \( \mathcal{N} \neq \mathcal{N}' \). It suffices to verify that

\[
\mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N} \neq \mathcal{G}' \vee \mathcal{C}_k \vee \mathcal{N}'
\]

because this contradicts the equalities

\[
\mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N} = \mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N} = \mathcal{V} = \mathcal{G}' \vee \mathcal{C}_k \vee \mathcal{N}' = \mathcal{G}' \vee \mathcal{C}_k \vee \mathcal{N}.
\]

We will say that varieties \( \mathcal{X}_1 \) and \( \mathcal{X}_2 \) differ with an identity \( u = v \) if this identity holds in one of the varieties \( \mathcal{X}_1 \) or \( \mathcal{X}_2 \) but fails in another one. Since \( \mathcal{N} \neq \mathcal{N}' \), the varieties \( \mathcal{N} \) and \( \mathcal{N}' \) differ with some identity. We may assume without loss of generality that this identity holds in \( \mathcal{N} \) but fails in \( \mathcal{N}' \). Suppose at first that the identity we mention is a 0-reduced identity \( u = 0 \). Since \( \mathcal{N}' \subseteq \mathcal{H} \), this identity fails in \( \mathcal{H} \). But all non-semigroup words as well as all non-linear semigroup words except \( x^2 \) equal to 0 in \( \mathcal{H} \). Therefore, either \( u \) is a linear word or \( u \equiv x^2 \). Suppose that \( u \equiv x_1 x_2 \cdots x_n \) for some \( n \). Then the identity \( x_1 x_2 \cdots x_n = 0 \) holds in \( \mathcal{N} \) but fails in \( \mathcal{N}' \). If \( m = 2 \) then the variety \( \mathcal{N} \) contains the variety \( \text{Nil}(\mathcal{C}_2) = \text{var}\{x^2 = 0, xy = yx\} \). The latest variety does not satisfy the identity \( x_1 x_2 \cdots x_n = 0 \). Therefore, \( m \leq 1 \). Then the variety \( \mathcal{G} \vee \mathcal{C}_m \) is completely regular. Lemmas 2.2 and 2.4 imply now that the variety \( \mathcal{G} \vee \mathcal{C}_m \vee \mathcal{N} \) satisfies the identity \( x_1 x_2 \cdots x_n = \overline{x_1 x_2 \cdots x_n} \). But Lemma 2.4
implies that this identity is false in $\overline{N}^\vee$ and therefore, in $G' \vee C_k \vee \overline{N}^\vee$. Thus, (8) holds. Let now $u \equiv x^2$. Then Lemmas 2.2, 2.3 and 2.4 imply that the identity $x^2 = \overline{x}^2$ holds in the variety $G \vee C_m \vee \overline{N}$ but is false in the variety $G' \vee C_k \vee \overline{N}^\vee$. We see again that the inequality (8) holds.

It remains to consider the case when $\overline{N}$ and $\overline{N}^\vee$ differ with some non-0-reduced identity $u = v$. Suppose that $c(u) \neq c(v)$. Lemma 2.6(i) then implies that the variety $\overline{N}$ satisfies both the identities $u = 0$ and $v = 0$. Then the variety $\overline{N}^\vee$ does not satisfy at least one of them because $\overline{N}$ and $\overline{N}^\vee$ do not differ with $u = v$ otherwise. We see that $\overline{N}$ and $\overline{N}^\vee$ differ with some 0-reduced identity, and we go to the situation considered in the previous paragraph. Let now $c(u) = c(v)$. Suppose that the identity $u = 0$ holds in $\mathcal{H}$. Since $\overline{N}, \overline{N}^\vee \subseteq \mathcal{H}$, we have that the identity $u = 0$ holds in both the varieties $\overline{N}$ and $\overline{N}^\vee$. Then $\overline{N}$ satisfies also the identity $v = 0$. But $v = 0$ fails in $\overline{N}^\vee$ because $u = v$ holds in $\overline{N}^\vee$ otherwise. We see that the varieties $\overline{N}$ and $\overline{N}^\vee$ differ with some 0-reduced identity. This case has been already considered in the previous paragraph. Thus the identity $u = v = 0$ fails in $\mathcal{H}$. Analogously, $v = 0$ fails in $\mathcal{H}$. As we have already mentioned in Case 1, all non-semigroup words as well as all non-linear semigroup words except $x^2$ equal to 0 in $\mathcal{H}$. Since the identity $u = v$ is non-trivial and $c(u) = c(v)$, the words $u$ and $v$ are linear. Using the fact that $c(u) = c(v)$ again, we have that the identity $u = v$ is permutative. Then it is evident that this identity holds in $G \vee C_m \vee \overline{N}$ but fails in $G' \vee C_k \vee \overline{N}^\vee$. We prove that the inequality (8) holds.

Thus, (8) fulfills always, whence we are done. □

Analog of Proposition 2.10 for semigroup varieties was proved in [18, Proposition 2a] (namely it was checked there that $L(G \vee C_2 \vee H) \cong L(G) \times L(C_2 \vee H)$ where $G$ is an abelian periodic group variety). The proof of Proposition 2.10 given above is quite similar to the proof of the mentioned result from [18]. But results of [18] was not used directly above. Therefore, the mentioned result from [18] may be considered now as a consequence of Proposition 2.10.

2.5. Varieties of finite degree. If $\mathcal{X}$ is not a variety of degree $\leq n$, we will say that $\mathcal{X}$ is a variety of degree $> n$. A variety is said to be a variety of finite degree if it is a variety of degree $n$ for some $n$. If $\mathcal{V}$ is a variety of finite degree, we denote the degree of $\mathcal{V}$ by $\deg(\mathcal{V})$; otherwise we put $\deg(\mathcal{V}) = \infty$. We need the following

Proposition 2.12 ([4, Corollary 1.2]). Let $n$ be an arbitrary natural number. For an epigroup variety $\mathcal{V}$, the following are equivalent:

1) $\deg(\mathcal{V}) \leq n$;
2) $\mathcal{V} \not\supseteq \operatorname{var}\{x^2 = x_1x_2 \cdots x_{n+1} = 0, \ xy = yx\}$;
3) $\mathcal{V}$ satisfies an identity of the form

\[
x_1 \cdots x_n = x_1 \cdots x_i \cdot \overline{x_{i+1} \cdots x_j \cdot x_{j+1} \cdots x_n}
\]

for some $i$ and $j$ with $1 \leq i \leq j \leq n$. □

Proposition 2.12 readily implies

Corollary 2.13. $\deg(\mathcal{X} \wedge \mathcal{Y}) = \min\{\deg(\mathcal{X}), \deg(\mathcal{Y})\}$ for arbitrary epigroup varieties $\mathcal{X}$ and $\mathcal{Y}$. □
The following corollary may be proved quite analogously to Corollary 2.13 of [22] with referring to Proposition 2.12 rather than Proposition 2.11 of [22].

**Corollary 2.14.** If \( V \) is an arbitrary epigroup variety and \( N \) is a nilvariety then 
\[
\deg(V \vee N) = \max\{\deg(V), \deg(N)\}.
\]

Note that the analog of Corollary 2.14 for arbitrary epigroup varieties is wrong even in the periodic case. For instance, it is easy to deduce from Lemma 2.5(iii), the dual fact and Proposition 2.12 that \( \deg(P) = \deg(P) = 2 \) but \( \deg(P \vee P) = 3 \).

Proposition 2.12 and Lemma 2.2 easily imply

**Corollary 2.15.** If \( V \) is an arbitrary epigroup variety and \( X \) is a completely regular variety then 
\[
\deg(V \vee X) = \deg(V).
\]

2.6. **Some properties of special elements of lattices.** The following claim is well known. It may be obtained by a combination of [3, Lemma 1], the dual statement and [2, Theorem 255 on p. 228].

**Lemma 2.16.** An element of a lattice \( L \) is neutral in \( L \) if and only if it is distributive, codistributive and modular in \( L \). \( \square \)

Let \( I \) be a lattice identity of the form \( s = t \) where \( s \) and \( t \) are lattice terms depending on ordering set of variables \( x_0, x_1, \ldots, x_n \). An element \( x \) of a lattice \( L \) is called an \( I \)-**element** if \( s(x_0, x_1, \ldots, x_n) = t(x_0, x_1, \ldots, x_n) \) for all \( x_1, \ldots, x_n \in L \). Special elements of all types mentioned above are \( I \)-elements for appropriate identities \( I \).

**Lemma 2.17** ([10, Corollary 2.1]). Let \( I \) be a non-trivial lattice identity, \( L \) a lattice with 0, \( x \in L \) and \( a \) an atom and a neutral element of the lattice \( L \). Then \( x \) is an \( I \)-element in \( L \) if and only if \( x \vee a \) has the same property. \( \square \)

2.7. **\( SL \) and \( ZM \) are atoms.** It is evident that atoms of the lattice \( Epi \) coincide with atoms of the lattice \( SEM \). The list of atoms of the latter lattice is generally known (see [16], for instance). In particular, the following is valid.

**Lemma 2.18.** The varieties \( SL \) and \( ZM \) are atoms of the lattice \( Epi \). \( \square \)

3. **The varieties \( SL \) and \( ZM \) are neutral**

The symbol \( \equiv \) stands for the equality relation on the unary semigroup \( F \).

**Proposition 3.1.** The variety \( SL \) is a neutral element of the lattice \( Epi \).

Proof. In view of Lemma 2.16, it suffices to verify that the variety \( SL \) is distributive, codistributive and modular. Let \( X \) and \( Y \) be arbitrary epigroup varieties.

**Distributivity.** We need to verify the inclusion 
\[
(SL \vee X) \land (SL \vee Y) \subseteq SL \vee (X \land Y)
\]

because the opposite inclusion is evident. Suppose that the identity \( u = v \) holds in \( SL \vee (X \land Y) \). In particular, it holds in \( SL \), whence \( c(u) = c(v) \) by Lemma 2.5(i). Let \( u \equiv w_0, w_1, \ldots, w_n \equiv v \) be a deduction of this identity
from identities of the varieties \( \mathcal{X} \) and \( \mathcal{Y} \). Further considerations are given by induction on \( n \).

**Induction base.** If \( n = 1 \) then the identity \( u = v \) holds in one of the varieties \( \mathcal{X} \) or \( \mathcal{Y} \). Whence, it holds in one of the varieties \( \mathcal{SL} \lor \mathcal{X} \lor \mathcal{SL} \lor \mathcal{Y} \), and therefore \( (\mathcal{SL} \lor \mathcal{X}) \lor (\mathcal{SL} \lor \mathcal{Y}) \) satisfies \( u = v \).

**Induction step.** Let now \( n > 1 \). Consider the words \( w'_1, \ldots , w'_{n-1} \) obtained from the words \( w_1, \ldots , w_{n-1} \) respectively by equating all the letters that are not occur in \( e \), for some letter of \( c(u) \). Clearly, the sequence of words \( u, w'_1, \ldots , w'_{n-1}, v \) also is a deduction of the identity \( u = v \) from identities of the varieties \( \mathcal{X} \) and \( \mathcal{Y} \). Thus, we may assume that \( c(w_1), \ldots , c(w_{n-1}) \subseteq c(u) \).

If \( c(w_0) = c(w_1) = \cdots = c(w_n) \) then the sequence \( w_0, w_1, \ldots , w_n \) is a deduction of the identity \( u = v \) from identities of the varieties \( \mathcal{SL} \lor \mathcal{X} \lor \mathcal{SL} \lor \mathcal{Y} \), and we are done. Suppose now that \( c(w_k) \neq c(w_{k+1}) \) for some \( 0 \leq k \leq n - 1 \). Let \( i \) be the least index with \( c(w_i) \neq c(w_{i+1}) \) and \( j \) be the greatest index with \( c(w_j) \neq c(w_{j-1}) \). Suppose that \( i > 0 \). Then \( c(w_i) = c(u) = c(v) \) and sequences of words \( w_0, w_1, \ldots , w_i \) and \( w_i, w_{i+1}, \ldots , w_n \) are deductions of the identities \( u = w_i \) and \( w_i = v \) respectively from the identities of the varieties \( \mathcal{X} \) and \( \mathcal{Y} \). Lemma 2.5(i) implies now that the identities \( u = w_i \) and \( w_i = v \) hold in the variety \( \mathcal{SL} \lor (\mathcal{X} \land \mathcal{Y}) \). By induction assumption these identities hold also in the variety \( (\mathcal{SL} \lor \mathcal{X}) \land (\mathcal{SL} \lor \mathcal{Y}) \). Whence, the last variety satisfies the identity \( u = v \) too. The case when \( j < n \) may be considered quite analogously. Thus, we may suppose that \( i = 0 \) and \( j = n \). In other words, \( c(u) \neq c(w_1) \) and \( c(v) \neq c(w_{n-1}) \).

The identity \( u = w_1 \) holds in one of the varieties \( \mathcal{X} \) and \( \mathcal{Y} \). Suppose that it holds in \( \mathcal{X} \). Since \( c(u) \neq c(w_1) \), Lemma 2.5(i) implies that \( \mathcal{SL} \not\subseteq \mathcal{X} \). Let \( S \) be an epigroup in \( \mathcal{X} \) and \( \zeta \) a homomorphism from \( F \) to \( S \). For a word \( w \), we denote by \( w' \) the image of \( w \) under \( \zeta \). It is well known (see [14, 15], for instance) that a variety that does not contain \( \mathcal{SL} \) consists of archimedean epigroups. Further, a set of group elements in an archimedean epigroup is an ideal of this epigroup.

In particular, this is the case for the epigroup \( S \). Now we are going to check that \( u' \in \text{Gr} \, S \). Since \( c(w_1) \subset c(u) \), there is a letter \( x \in c(u) \setminus c(w_1) \). Substituting \( x' \) for \( x \) in the identity \( u = w_1 \), we obtain the identity \( u' = w_1 \) that holds in \( \mathcal{X} \). Therefore, \( \mathcal{X} \) satisfies the identity \( u = u' \). The word \( u' \) contains a subword \( x'' \). Since \( (x'')' \in \text{Gr} \, S \) and \( \text{Gr} \, S \) is an ideal in \( S \), we have that \( u'' \in \text{Gr} \, S \). Therefore, \( \mathcal{X} \) satisfies the identity \( u = uu'' \). Similar arguments show that the identity \( u = uu'' \) holds in \( \mathcal{Y} \) whenever \( \mathcal{Y} \) satisfies \( u = w_1 \), and that one of the varieties \( \mathcal{X} \) and \( \mathcal{Y} \) satisfies the identity \( v = vv'' \). Therefore, the sequence of words

\[ u, uu'', w_1u'', \ldots , w_{n-1}u'', vv'', vv''', \ldots , v' \]

is a deduction of the identity \( u = v \) from identities of the varieties \( \mathcal{SL} \lor \mathcal{X} \) and \( \mathcal{SL} \lor \mathcal{Y} \). Hence this identity holds in \( (\mathcal{SL} \lor \mathcal{X}) \lor (\mathcal{SL} \lor \mathcal{Y}) \).

**Codistributivity.** In view of Lemma 2.18, if \( \mathcal{W} \) is an arbitrary epigroup variety then either \( \mathcal{W} \supseteq \mathcal{SL} \) or \( \mathcal{W} \lor \mathcal{SL} = \mathcal{T} \). We need to verify that

\[ \mathcal{SL} \lor (\mathcal{X} \lor \mathcal{Y}) = (\mathcal{SL} \lor \mathcal{X}) \lor (\mathcal{SL} \lor \mathcal{Y}) \].
Clearly, both the parts of this equality coincides with $SL$ whenever at least one of the varieties $X$ or $Y$ contains $SL$. It remains to verify that if $X \nsubseteq SL$ and $Y \nsubseteq SL$ then $X \cup Y \nsubseteq SL$. This claim immediately follows from the fact that there is a non-trivial identity $u = v$ such that an epigroup variety $W$ does not contain the variety $SL$ if and only if $W$ satisfies the identity $u = v$ (in particular, the identity $(x^\omega y^\omega x^\omega)^\omega = x^\omega$ has such a property, see [15, Corollary 3.2], for instance).

**Modularity.** Let $X \subseteq Y$. We need to verify that
\[(SL \vee X) \land Y \subseteq (SL \land Y) \vee X\]
because the opposite inclusion is evident. If $SL \subseteq Y$ then both the parts of the inclusion evidently coincides with $SL \vee X$. Let now $SL \nsubseteq Y$. Then Lemma 2.18 implies that $SL \land Y = T$, whence $(SL \land Y) \vee X = X$. Suppose that an identity $u = v$ holds in the variety $X$. It suffices to verify that this identity holds in $(SL \vee X) \land Y$ too. If $c(u) = c(v)$ then $u = v$ holds in $SL$ by Lemma 2.5(i). Whence it satisfies in $SL \vee X$, and we are done. Let now $c(u) \neq c(v)$. Since $SL \nsubseteq Y$, Lemma 2.5(i) implies that $Y$ satisfies an identity $s = t$ with $c(s) \neq c(t)$. We may assume without any loss that there is a letter $y \in c(t) \setminus c(s)$. Moreover, we may assume that $c(s) = \{x\}$ and $c(t) = \{x, y\}$ (if this is not the case then we equate all letters but $y$ to $x$ in the identity $s = t$ and multiply the identity we obtain on $x$ from the right). Let $s_1$ [respectively $t_1$] be the word obtained from the word $s$ [respectively $t$] by replacing the letters $x$ and $y$ each to other. Clearly, the identity $s_1 = t_1$ follows from the identity $s = t$.

Consider the case when the word $v$ may be obtained from $u$ by replacing of one letter to another one. We may assume without loss of generality that we substitute the letter $y$ for the letter $x$. Let $u_1$, $u_2$, $u_3$ and $u_4$ be the words obtained from $u$ by substitution of the words $s$, $s_1$, $t$ and $t_1$ respectively for the letter $x$. Since $x \notin c(v)$, the identities $u_1 = v$, $u_2 = v$, $u_3 = v$ and $u_4 = v$ are obtained from $u = v$ by the same substitutions. Therefore, the words $u$, $v$, $u_1$, $u_2$, $u_3$ and $u_4$ are equal each to other in the variety $X$. Further, $c(u) = c(u_1)$, $c(v) = c(u_2)$ and $c(u_3) = c(u_4)$, whence the identities $u = u_1$, $v = u_2$ and $u_3 = u_4$ hold in $SL \vee X$ by Lemma 2.5(i). The identities $u_1 = u_3$ and $u_2 = u_4$ follow from $s = t$ and $s_1 = t_1$ respectively. Hence these identities hold in $Y$. Thus, the sequence of words $u$, $u_1$, $u_3$, $u_4$, $u_2$, $v$ is a deduction of the identity $u = v$ from the identities of the varieties $SL \vee X$ and $Y$.

Finally, consider an arbitrary identity $u = v$ that holds in $X$. Replacing one by one all the letters from $c(u) \setminus c(v)$ by some letters of $c(v)$, we obtain the sequence $u, w_1, \ldots, w_m$, in which any adjacent words differ by replacing one letter. In the sequence of identities $u = v, w_1 = v, \ldots, w_m = v$, every identity (except the first one) is obtained from the previous one by replacing one letter. Therefore the words $u, w_1, \ldots, w_m$ are equal each to other in $X$. As we have proved above, this implies that the identities $u = w_1 = \cdots = w_m$ hold in $(SL \vee X) \land Y$. Analogously, if we replace in the identity $v = w_m$ all letters from $c(v) \setminus c(w_m)$ by an arbitrary letter from $c(w_m)$, then we obtain a sequence of identities $v = w'_1 = \cdots = w'_n$ that hold in $(SL \vee X) \land Y$ as well. In particular, these identities hold in $X$. Moreover, since $c(w_m) = c(w'_n)$,
Lemma 2.5(i) implies that the identity $w_m = w'_n$ holds in $\mathcal{SL} \lor \mathcal{X}$. Therefore, the identity $u = v$ holds in $(\mathcal{SL} \lor \mathcal{X}) \land \mathcal{Y}$. □

**Proposition 3.2.** The variety $\mathcal{ZM}$ is a neutral element of the lattice $\mathcal{Epi}$.

*Proof.* In view of Lemma 2.16, it suffices to check that $\mathcal{ZM}$ is distributive, codistributive and modular. Let $\mathcal{X}$ and $\mathcal{Y}$ be arbitrary epigroup varieties.

**Distributivity.** We need to verify that

$$(\mathcal{ZM} \lor \mathcal{X}) \land (\mathcal{ZM} \lor \mathcal{Y}) \subseteq \mathcal{ZM} \lor (\mathcal{X} \land \mathcal{Y})$$

because the opposite inclusion is evident. Suppose that an identity $u = v$ holds in $\mathcal{ZM} \lor (\mathcal{X} \land \mathcal{Y})$. We aim to check that this identity is satisfied by the variety $(\mathcal{ZM} \lor \mathcal{X}) \land (\mathcal{ZM} \lor \mathcal{Y})$. The identity $u = v$ holds in $\mathcal{ZM}$ and there is a deduction of this identity from identities of the varieties $\mathcal{X}$ and $\mathcal{Y}$. In other words, there are words $u_0, u_1, \ldots, u_n$ such that $u_0 \equiv u$, $u_n \equiv v$ and, for each $i = 0, 1, \ldots, n - 1$, the identity $u_i = u_{i+1}$ holds in one of the varieties $\mathcal{X}$ and $\mathcal{Y}$. Let $u_0, u_1, \ldots, u_n$ be the shortest sequence of words with such properties. If all the words $u_0, u_1, \ldots, u_n$ are not letters then $u_0 = u_1 = \cdots = u_n$ holds in $\mathcal{ZM}$. This means that the sequence of words $u_0, u_1, \ldots, u_n$ is a deduction of the identity $u = v$ from identities of the varieties $\mathcal{ZM} \lor \mathcal{X}$ and $\mathcal{ZM} \lor \mathcal{Y}$, whence $u = v$ holds in $((\mathcal{ZM} \lor \mathcal{X}) \land (\mathcal{ZM} \lor \mathcal{Y}))$. Let now $i$ be an index such that $u_i \equiv x$ for some letter $x$. Clearly, $0 < i < n$ because the variety $\mathcal{ZM}$ satisfies the identity $u_0 = u_n$ but does not satisfy any identity of the kind $x = w$. The identity $u_{i-1} = x$ holds in one of the varieties $\mathcal{X}$ and $\mathcal{Y}$, say in $\mathcal{X}$. Then $\mathcal{Y}$ satisfies the identity $x = u_{i+1}$. Since both the identities $u_{i-1} = x$ and $x = u_{i+1}$ fail in $\mathcal{ZM}$, we have that $\mathcal{ZM}$ is contained neither in $\mathcal{X}$ nor in $\mathcal{Y}$. Therefore, the varieties $\mathcal{X}$ and $\mathcal{Y}$ are completely regular. By Lemma 2.2 each of the identities $u_0 = \overline{u_0}$ and $u_n = u_n$ holds in one of the varieties $\mathcal{X}$ and $\mathcal{Y}$. Further, for each $i = 0, 1, \ldots, n - 1$ one of the varieties $\mathcal{X}$ and $\mathcal{Y}$ satisfies the identity $u_i \equiv \overline{u_i}$ and $u_i \equiv u_{i+1}$. The words $u_0$ and $u_n$ are not letters, whence the variety $\mathcal{ZM}$ satisfies the identities $u_0 = \overline{u_0} = \overline{u_1} = \cdots = \overline{u_n} = u_n$. Summarizing all we say, we obtain that the sequence of words $u_0, u_0, u_1, \ldots, u_n, u_n$ is a deduction of the identity $u = v$ from the identities of the varieties $\mathcal{ZM} \lor \mathcal{X}$ and $\mathcal{ZM} \lor \mathcal{Y}$. Therefore, this identity holds in $(\mathcal{ZM} \lor \mathcal{X}) \land (\mathcal{ZM} \lor \mathcal{Y})$.

**Codistributivity.** In view of Lemma 2.18, if $\mathcal{W}$ is an arbitrary epigroup variety then either $\mathcal{W} \supseteq \mathcal{ZM}$ or $\mathcal{W} \land \mathcal{ZM} = T$. We need to verify that

$$\mathcal{ZM} \land (\mathcal{X} \lor \mathcal{Y}) = (\mathcal{ZM} \land \mathcal{X}) \lor (\mathcal{ZM} \land \mathcal{Y}).$$

Clearly, both the parts of this equality equals $\mathcal{ZM}$ whenever at least one of the varieties $\mathcal{X}$ or $\mathcal{Y}$ contains $\mathcal{ZM}$. It remains to verify that if $\mathcal{X} \nsubseteq \mathcal{ZM}$ and $\mathcal{Y} \nsubseteq \mathcal{ZM}$ then $\mathcal{X} \lor \mathcal{Y} \nsubseteq \mathcal{ZM}$. This claim immediately follows from the well-known fact that an epigroup variety $\mathcal{W}$ does not contain the variety $\mathcal{ZM}$ if and only if $\mathcal{W}$ is completely regular.

**Modularity.** For any epigroup variety $\mathcal{X}$, we put $\mathrm{CR}(\mathcal{X}) = \mathcal{CR} \land \mathcal{X}$ where $\mathcal{CR}$ is the variety of all completely regular epigroups. Suppose that $\mathcal{X} \subseteq \mathcal{Y}$. We need to prove that

$$(\mathcal{ZM} \lor \mathcal{X}) \land \mathcal{Y} \subseteq (\mathcal{ZM} \land \mathcal{Y}) \lor \mathcal{X}$$
because the opposite inclusion is evident. If \( ZM \subseteq X \) [respectively \( ZM \subseteq Y \)] then both the parts of the inclusion (10) coincide with \( X \) [with \( ZM \lor X \)]. Let now \( ZM \not\subseteq X \) and \( ZM \not\subseteq Y \). Then the varieties \( X \) and \( Y \) are completely regular. Therefore,

\[
(ZM \lor X) \land Y \subseteq CR(ZM \lor X).
\]

Further, \( ZM \land Y = T \), whence the right part of the inclusion (10) coincides with \( X \). Let \( u = v \) be an identity that holds in \( X \). Lemmas 2.2 and 2.4 imply that \( ZM \lor X \) satisfies the identity \( u = v \). Therefore, \( u = v \) in \( CR(ZM \lor X) \) by Lemma 2.2. We have proved that \( CR(ZM \lor X) \subseteq X \), whence

\[
(ZM \lor X) \land Y \subseteq CR(ZM \lor X) \subseteq X = T \lor X = (ZM \land Y) \lor X.
\]

Proposition is proved. \( \square \)

For convenience of references, we formulate the following fact that immediately follows from Lemmas 2.17 and 2.18 and Propositions 3.1 and 3.2.

**Corollary 3.3.** Let \( I \) be a non-trivial lattice identity and \( W \) is one of the varieties \( SL, ZM \) and \( SL \lor ZM \). An epigroup variety \( X \) is an \( I \)-element of the lattice \( Epi \) if and only if the variety \( X \lor W \) has the same property. \( \square \)

### 4. Upper-modular varieties

Here we verify Theorem 1.5. To do this, we need several auxiliary statements.

**Lemma 4.1.** If a strongly permutative epigroup variety \( V \) is an upper-modular element of the lattice \( Epi \) then \( V \) is commutative.

**Proof.** In view of Corollary 2.9, \( V = G \lor C \lor N \) where \( G \) is an abelian group variety, \( m \geq 0 \) and \( N \) is a nilvariety. If \( \deg(V) \leq 2 \) then \( N \subseteq ZM \), and we are done. Let now \( \deg(V) > 2 \). By Proposition 2.12 \( V \) contains the variety \( X = \text{var}\{x^2 = xyz = 0, xy = yx\} \). Suppose that \( V \) is not commutative. Let \( G' \) be a non-abelian group variety. Since \( V \) is strongly permutative, every group in \( V \) is abelian. Therefore, the variety \( (G' \land V) \lor X \) is commutative. Since \( X \subseteq V \) and the variety \( V \) is upper-modular, we have that \( (G' \land V) \lor X = (G' \lor X) \land V \). We see that the variety \( (G' \lor X) \land V \) is commutative. Hence there is a deduction of the identity \( xy = yx \) from the identities of the varieties \( G' \lor X \) and \( V \). In particular, there is a word \( v \) such that \( v \neq xy \) and the identity \( xy = v \) holds either in \( G' \lor X \) or in \( V \). The claims (i) and (iii) of Lemma 2.6 imply that a variety with the identity \( xy = v \) is either commutative or a variety of degree \( \leq 2 \). The variety \( G' \lor X \) is neither commutative (because \( G' \) is non-abelian) nor a variety of degree \( \leq 2 \) (because \( \deg(X) > 2 \)). Since \( \deg(V) > 2 \), we have that \( V \) is commutative. \( \square \)

A semigroup variety is called **proper** if it differs from the variety of all semigroups. It is proved in [22, Theorem 1.1] that if \( V \) is a proper upper-modular in \( SEM \) variety then, first, \( V \) is periodic, and, second, every nilsubvariety of

\[\text{Note that this is a very special case of the following result obtained in [12, Theorem 1]: if } I \text{ is a non-trivial lattice identity then a proper semigroup variety is periodic whenever it is an } I\text{-element of the lattice } SEM.\]
\( \mathcal{V} \) is commutative and satisfies the identity (2). As we have already mentioned in Subsection 1.2, the epigroup analog of the first claim is not true. Our next step is the following partial epigroup analog of the second claim.

**Proposition 4.2.** If a strongly permutative epigroup variety \( \mathcal{V} \) is an upper-modular element of the lattice \( \text{Epi} \) then every nil-semigroup in \( \mathcal{V} \) satisfies the identity (2).

**Proof.** According to Lemma 4.1 the variety \( \mathcal{V} \) is commutative. If all nil-semigroups in \( \mathcal{V} \) are singleton then the desirable conclusion is evident. Suppose now that \( \mathcal{V} \) contains a non-singleton nil-semigroup \( N \). Let \( N \) be the variety generated by \( N \). Clearly, this variety is commutative. It is evident that \( \mathcal{ZM} \subseteq N \).

We need to verify that \( N \) satisfies the identity (2). Put

\[
I = \text{var}\{x^2y = xy^2, xy = yx, x^2yz = 0\}
\]

and \( N' = N \cap I \). It is clear that \( \mathcal{ZM} \subseteq I \), whence \( \mathcal{ZM} \subseteq N' \).

A semigroup analog of the proposition we verify is proved in [22] (see the last paragraph of Section 3 in that article). The arguments used there are based on the fact that there is a variety \( \mathcal{X} \) such that the following two claims are valid:

(i) \( (\mathcal{X} \vee N') \cap \mathcal{V} \subseteq I \);

(ii) if \( v \in \{x^2y, xyx, yx^2\} \) and \( w \in \{xy^2, yxy, y^2x\} \) then the identity \( v = w \) fails in \( \mathcal{X} \).

In [22] some periodic group variety plays the role of \( \mathcal{X} \). Here we should take another \( \mathcal{X} \). Namely, put \( \mathcal{X} = \text{LZM} \vee \text{RZM} \) where

\[
\text{LZM} = \text{var}\{xyz = xy\} \quad \text{and} \quad \text{RZM} = \text{var}\{xyz = yz\}.
\]

The variety \( \mathcal{X} \) satisfies the identity \( xzxy = xy \). Therefore, Lemma 2.5(i) implies that \( \mathcal{SL} \not\subseteq \mathcal{X} \). Further, substituting 1 for \( x \) and \( y \) in the identity \( xzxy = xy \), we obtain that all groups in \( \mathcal{X} \) are singleton. Hence every commutative semigroup in \( \mathcal{X} \) is a nil-semigroup. Further, \( \mathcal{X} \) satisfies the identity \( xy = (xy)^2 \), whence all nil-semigroups in \( \mathcal{X} \) lie in \( \mathcal{ZM} \) by Lemma 2.6(ii).

Since the variety \( \mathcal{X} \cap \mathcal{V} \) is commutative, \( \mathcal{X} \cap \mathcal{V} \subseteq \mathcal{ZM} \). The variety \( \mathcal{V} \) is upper-modular and \( \mathcal{N'} \subseteq \mathcal{V} \). Therefore,

\[
(\mathcal{X} \vee \mathcal{N'}) \cap \mathcal{V} = (\mathcal{X} \cap \mathcal{V}) \vee \mathcal{N'} \subseteq \mathcal{ZM} \vee \mathcal{N'} = \mathcal{N'} \subseteq I.
\]

We have proved the claim (i). To verify the claim (ii), we note that if \( \mathcal{X} \) satisfies a semigroup identity \( v = w \) then the words \( v \) and \( w \) have the same prefix of length 2 and the same suffix of length 2. Clearly, this is not the case whenever \( v \in \{x^2y, xyx, yx^2\} \) and \( w \in \{xy^2, yxy, y^2x\} \). Now we can complete the proof by the same arguments as in the last paragraph of [22, Section 3]. \( \square \)

The proof of the following statement repeats almost literally the ‘only if’ part of the proof of Theorem 2 in [27].

**Proposition 4.3.** If a nilvariety of epigroups \( \mathcal{X} \) satisfies the identities (2) and \( xy = yx \) then \( \mathcal{X} \) is an upper-modular element of the lattice \( \text{Epi} \).

**Proof.** It is easy to prove (see [27, Lemma 2.7], for instance) that \( \mathcal{X} \) satisfies the identity \( x^2yz = 0 \). Thus, \( \mathcal{X} \subseteq I \). Put

\[
U = \{x^2, x^3, x^2y, x_1x_2 \cdots x_n \mid n \in \mathbb{N}\}.
\]
It is evident that any subvariety of \( \mathcal{I} \) may be given in \( \mathcal{I} \) only by identities of the type \( u = v \) or \( u = 0 \) where \( u, v \in U \). Lemma 2.6 implies that if \( u, v \in U \) and \( u \neq v \) then \( u = v \) implies in \( \mathcal{I} \) the identity \( u = 0 \). Now it is very easy to check that the lattice \( L(\mathcal{I}) \) has the form shown on Fig. 1 where

\[
\begin{align*}
\mathcal{I}_n &= \text{var}\{x^2yz = x_1x_2 \cdots x_n = 0, x^2y = xy^2, xy = yx\} \text{ where } n \geq 4, \\
\mathcal{J} &= \text{var}\{x^2yz = x^3 = 0, x^2y = xy^2, xy = yx\}, \\
\mathcal{J}_n &= \text{var}\{x^2yz = x^3 = x_1x_2 \cdots x_n = 0, x^2y = xy^2, xy = yx\} \text{ where } n \geq 4, \\
\mathcal{K} &= \text{var}\{x^2y = 0, xy = yx\}, \\
\mathcal{K}_n &= \text{var}\{x^2y = x_1x_2 \cdots x_n = 0, xy = yx\} \text{ where } n \geq 3, \\
\mathcal{L} &= \text{var}\{x^2 = 0, xy = yx\}, \\
\mathcal{L}_n &= \text{var}\{x^2 = x_1x_2 \cdots x_n = 0, xy = yx\} \text{ where } n \in \mathbb{N}.
\end{align*}
\]

Note that \( \mathcal{L}_1 = \mathcal{T} \) and \( \mathcal{L}_2 = \mathcal{ZM} \).

Let \( \mathcal{X} \subseteq \mathcal{I} \). We have to check that if \( \mathcal{Y} \subseteq \mathcal{X} \) and \( \mathcal{Z} \) is an arbitrary epigroup variety then \( (\mathcal{Z} \vee \mathcal{Y}) \wedge \mathcal{X} = (\mathcal{Z} \wedge \mathcal{X}) \vee \mathcal{Y} \). For a variety \( \mathcal{M} \) with \( \mathcal{M} \subseteq \mathcal{I} \), we denote by \( \mathcal{M}^* \) the least of the varieties \( \mathcal{I}, \mathcal{J}, \mathcal{K} \) and \( \mathcal{L} \) that contains \( \mathcal{M} \). Fig. 1 shows that if \( \mathcal{M}_1, \mathcal{M}_2 \subseteq \mathcal{I} \) then \( \mathcal{M}_1 = \mathcal{M}_2 \) if and only if \( \deg(\mathcal{M}_1) = \deg(\mathcal{M}_2) \) and \( \mathcal{M}_1^* = \mathcal{M}_2^* \). Therefore, we have to verify the following two equalities:

\[
\deg((\mathcal{Z} \vee \mathcal{Y}) \wedge \mathcal{X}) = \deg((\mathcal{Z} \wedge \mathcal{X}) \vee \mathcal{Y}),
\]
\[(12) \quad ((Z \lor Y) \land X)^* = ((Z \land X) \lor Y)^*.\]

The equality (11). Put \(\deg(X) = k\), \(\deg(Y) = \ell\) and \(\deg(Z) = m\). According to Corollaries 2.13 and 2.14, we have
\[
\deg((Z \lor Y) \land X) = \min\{\max\{m, \ell\}, k\},
\deg((Z \land X) \lor Y) = \max\{\min\{m, k\}, \ell\}.
\]
Clearly, \(\ell \leq k\) because \(Y \subseteq X\). It is then evident that
\[
\min\{\max\{m, \ell\}, k\} = \max\{\min\{m, k\}, \ell\} = \begin{cases} 
\ell & \text{if } m \leq \ell \leq k, \\
\ell & \text{if } \ell \leq m \leq k, \\
k & \text{if } \ell \leq k \leq m.
\end{cases}
\]
The equality (11) is proved.

The equality (12). Clearly, this equality is equivalent to the following claim: if \(u\) is one of the words \(x^3, x^2y\) and \(x^2\) then the variety \((Z \lor Y) \land X\) satisfies the identity \(u = 0\) if and only if the variety \((Z \land X) \lor Y\) does so. It suffices to verify that \(u = 0\) holds in \((Z \lor Y) \land X\) whenever it is so in \((Z \land X) \lor Y\) because the opposite claim immediately follows from the evident inclusion \((Z \land X) \lor Y \subseteq (Z \lor Y) \land X\). Further considerations are divided into two cases.

**Case 1:** \(u \equiv x^n\) where \(n \in \{2, 3\}\). This case may be considered quite analogously to Case 1 in the ‘only if’ part of the proof of Theorem 2 in [27], but one additional ingredient is required. The mentioned fragment of considerations in [27] may be non-formally divided into two steps. First, it was verified there that it suffices to prove the following claim: if the variety \(Z\) satisfies an identity of the form \(x^n = v\) for some word \(v\) then the identity \(x^n = 0\) holds in the variety \((Z \lor Y) \land X\). The second step is a verification of this claim. We may now repeat literally the first step for arbitrary word \(v\) and the second one whenever \(v\) is a semigroup word. The mentioned additional ingredient is the following evident observation: if \(v\) is a non-semigroup word then the variety \(X\) and \((Z \lor Y) \land X\) also satisfies the identities \(x^n = v = 0\) by Lemma 2.4.

**Case 2:** \(u \equiv x^2y\). We have to check that if the variety \((Z \land X) \lor Y\) satisfies the identity (1) then the variety \((Z \lor Y) \land X\) also satisfies this identity. The fact that \(X\) is a nilvariety easily implies that
\[(13) \quad (Z \lor Y) \land X = \text{Nil}(Z \lor Y) \land X.\]
Put
\[W = \{x^2y, xyx, yx^2, y^2x, yxy, xy^2\}.
\]
The variety \((Z \lor Y) \land X\) is commutative. Therefore, it suffices to verify that this variety satisfies an identity \(w = 0\) for some word \(w \in W\). By the hypothesis the variety \((Z \land X) \lor Y\) satisfies the identity (1). This means that this identity holds in \(Y\) and there is a deduction of the identity from identities of the varieties \(X\) and \(Z\). Let \(x^2y \equiv u_0, u_1, \ldots, u_n, 0\) be an arbitrary such deduction. The case when \(u_n \in W\) may be considered by the same way as in the ‘only if’ part of the proof of Theorem 2 in [27].

Let now \(u_n \notin W\). Since \(u_0 \in W\), there is an index \(i > 0\) such that \(u_i \notin W\) while \(u_{i-1} \in W\). The identity \(u_{i-1} = u_i\) holds in one of the varieties \(Z\) and
\( X \). If \( u_{i-1} = u_i \) holds in \( X \) then \( X \) satisfies the identity \( u_{i-1} = 0 \) (this follows from [27, Lemma 2.5] whenever \( u_i \) is a semigroup word and from Lemma 2.4 otherwise). Therefore, \( u_{i-1} = 0 \) holds in \((Z \lor Y) \land X\). Since \( u_{i-1} \in W \), we are done.

Finally, suppose that \( u_{i-1} = u_i \) holds in \( Z \). If \( u_i \) is a semigroup word then we may complete the proof by the same arguments as in the 'only if' part of the proof of Theorem 2 in [27]. Suppose now that the word \( u_i \) is not a semigroup word. Suppose at first that there is a letter \( z \in c(u_i) \setminus \{x, y\} \). In view of the identity (3), we may assume that \( u_i = rzt \) for some (maybe empty) words \( r \) and \( t \) such that the word \( rt \) is non-empty and moreover, \( z \in c(rt) \). Substitute \( u^2_{i-1} \) for \( z \) in the identity \( u_{i-1} = u_i \). We obtain an identity of the type \( u_{i-1} = w_1u^2_{i-1}w_2 \) for some (maybe empty) words \( w_1 \) and \( w_2 \). This identity holds in \( Z \lor Y \) because \( u_{i-1} = u_i \) in \( Z \) and \( u_{i-1} = 0 \) in \( Y \). By Lemma 2.6(ii) \( u_{i-1} = 0 \) holds in \( \text{Nil}(Z \lor Y) \), and moreover in \( \text{Nil}(Z \lor Y) \land X \). We are done by (13). Finally, the case when \( c(u_i) \subseteq \{x, y\} \) may be considered by the same arguments as in the 'only if' part of the proof of Theorem 2 in [27].

The equality (12) is proved. Thus, we have proved Proposition 4.3. \( \square \)

**Proof of Theorem 1.5. Necessity.** Let \( V \) be a strongly permutative upper-modular epigroup variety. In view of Corollary 2.9, \( V = G \lor C_m \lor N \) where \( G \) is an abelian group variety, \( m \geq 0 \) and \( N \) is a nilvariety. Lemma 4.1 and Proposition 4.2 imply respectively that \( N \) is commutative and satisfies the identity (2). The variety \( C_m \) contains a nilsubvariety \( \text{var}\{x^m = 0, xy = yx\} \). Clearly, this variety does not satisfy the identity (2) whenever \( m \geq 3 \). Now Proposition 4.2 applies again and we conclude that \( m \leq 2 \). If the variety \( N \) satisfies the identity (1) then the claim (ii) of Theorem 1.5 holds. Suppose now that the identity (1) fails in \( N \). By [29, Lemma 7] this implies that \( N \) contains the variety \( J \). We need to verify that \( G = T \) and \( m \leq 1 \). Arguing by contradiction, suppose that either \( G \neq T \) or \( m \geq 2 \). Then \( V \) contains a variety of the form \( X \lor J \) where \( X \) is either a non-trivial abelian group variety or the variety \( C_2 \). It is well known and may be easily checked that the variety \( C_2 \) is generated by the epigroup

\[
C_2 = \langle e, a \mid e^2 = e, ea = ae = a, a^2 = 0 \rangle = \{e, a, 0\}
\]

and \( e \) is the unit of \( C_2 \). Thus, \( M \) is generated by an epigroup with unit in any case. Suppose that \( X \) satisfies the identity (2). Substituting 1 for \( y \) in this identity, we have that \( x^2 = x \) holds in \( X \). But this identity is false both in a non-trivial group variety and in the variety \( C_2 \). As it is verified in the proof of [29, Lemma 8], this implies that (2) is false in any nil-semigroup in \( X \lor J \). But this contradicts Proposition 4.2.

**Sufficiency.** If \( V \) satisfies the claim (i) of Theorem 1.5 then \( V \) is upper-modular by Proposition 4.3 and Corollary 3.3. Suppose now that \( V \) satisfies the claim (ii). In other words, \( V = G \lor C_m \lor N \) where \( G \) is an abelian group variety, \( 0 \leq m \leq 2 \), and \( N \) satisfies the identities \( xy = yx \) and (1). Let \( Y \subseteq V \) and \( Z \) an arbitrary epigroup variety. We aim to verify that

\[
(Z \lor Y) \land V = (Z \land V) \lor Y.
\]
As we have already mentioned in the proof of Lemma 2.8, the variety $C_m$ is generated by the $(m + 1)$-element combinatorial cyclic monoid $C_m$ and the set $X = \{ m \in \mathbb{N} | C_m \in \mathcal{X} \}$ has the greatest element. For any $m \geq 0$, let $c_m$ be a generator of $C_m$. Put $C = \prod_{m \in X} C_m$. Then the semigroup $C$ is not an epigroup because no power of the element $(\ldots, c_m, \ldots)_{m \in X}$ belongs to a subgroup of $C$. Thus, the set $X$ has the greatest element. We denote this element by $m$ and put $C(\mathcal{X}) = C_m$. It is clear that the varieties $(Z \lor Y) \land V$ and $(Z \land V) \lor Y$ are commutative. In view of Corollary 2.9, it suffices to verify the following three equalities:

\begin{align}
\text{(14)} & \quad \text{Gr}((Z \lor Y) \land V) = \text{Gr}((Z \land V) \lor Y), \\
\text{(15)} & \quad C((Z \lor Y) \land V) = C((Z \land V) \lor Y), \\
\text{(16)} & \quad \text{Nil}((Z \lor Y) \land V) = \text{Nil}((Z \land V) \lor Y). 
\end{align}

The equality (14). If $G$ is a periodic group variety then we denote by $\text{exp}(G)$ the exponent of $G$, that is the least number $n$ such that $G$ satisfies the identity $x = x^{n+1}$. For a non-periodic group variety $G$, we put $\text{exp}(G) = \infty$. As usual, we denote by $\text{lcm}\{m, n\}$ [respectively $\text{gcd}\{m, n\}$] the least common multiple [the greatest common divisor] of positive integers $m$ and $n$. To simplify further considerations, we will assume that any natural number divides $\infty$; in particular, $\text{gcd}\{n, \infty\} = n$ and $\text{lcm}\{n, \infty\} = \infty$ for arbitrary natural $n$. We will assume also that $\text{gcd}\{\infty, \infty\} = \text{lcm}\{\infty, \infty\} = \infty$. Put $G_1 = \text{Gr}((Z \lor Y) \land V)$ and $G_2 = \text{Gr}((Z \land V) \lor Y)$. Since $G_1, G_2 \subseteq Y$, we have that $G_1$ and $G_2$ are abelian group varieties. To prove the equality (14), it suffices to verify that $\text{exp}(G_1) = \text{exp}(G_2)$. This claim is verified by the same arguments as the analogous claim in the proof of Theorem 1.2 in [22].

The equality (15). Here and below we need the following easy remark. It is evident that if $m \geq 3$ then the identity (1) fails in the variety $\text{Nil}(C_m) = \text{var}\{x^m = 0, xy = yx\}$. This means that each part of the equality (15) coincides with the variety $C_m$ for some $0 \leq m \leq 2$. Then we may complete the proof of equality (15) by the same arguments as in the proof of the equality (4.2) in [22].

The equality (16). The varieties $G$, $C_2$ and $N$ satisfy the identity $x^2y = \overline{y}^2y$. By Lemma 2.4 the variety $\text{Nil}(V)$ satisfies the identity (1). Fig. 1 shows that it suffices to check the following two claims: first, the varieties $(Z \lor Y) \land V$ and $(Z \land V) \lor Y$ have the same degree, and second, the variety $\text{Nil}((Z \lor Y) \land V)$ satisfies the identity

\begin{equation}
\text{(17)} \quad x^2 = 0
\end{equation}

if and only if the variety $\text{Nil}((Z \land V) \lor Y)$ satisfies this identity. The former claim may be verified by the same way as in the proof of the equality (4.3) in [22] with references to Proposition 2.12, Corollary 2.14 and Corollary 2.15 of the present article rather than Proposition 2.11, Lemma 2.13 and Lemma 2.12 of [22] respectively.

It remains to verify that the variety $\text{Nil}((Z \lor Y) \land V)$ satisfies the identity (17) whenever $\text{Nil}((Z \land V) \lor Y)$ does so (because the opposite claim is
evident). Suppose that the identity (17) holds in Nil((\mathcal{Z} \land \mathcal{V}) \lor \mathcal{Y}). Corollary 2.9 imply that the variety (\mathcal{Z} \land \mathcal{V}) \lor \mathcal{Y} is the join of some group variety, the variety \mathcal{C}_m for some \( m \geq 0 \) and the variety Nil((\mathcal{Z} \land \mathcal{V}) \lor \mathcal{Y}). Here \( m \leq 2 \) because (\mathcal{Z} \land \mathcal{V}) \lor \mathcal{Y} \subseteq \mathcal{V}. This implies that the variety (\mathcal{Z} \land \mathcal{V}) \lor \mathcal{Y} satisfies the identity \( x^2 = \overline{x^2} \). In particular, this identity holds in both the varieties \( \mathcal{Y} \) and \( \mathcal{Z} \land \mathcal{V} \). Therefore, there is a sequence of words \( u_0, u_1, \ldots, u_k \) such that \( u_0 \equiv x^2, u_k \equiv \overline{x^2} \) and, for each \( i = 0, 1, \ldots, k - 1 \), the identity \( u_i = u_{i+1} \) holds in one of the varieties \( \mathcal{Z} \) or \( \mathcal{V} \). We may assume that \( u_i \neq u_{i+1} \) for each \( i = 0, 1, \ldots, k - 1 \). Arguments from the proof of the equality (4.3) in [22] show that it suffices to check that the identity (17) holds in one of the varieties Nil(\( \mathcal{Z} \)) or Nil(\( \mathcal{V} \)). This fact follows from Lemma 2.6 whenever \( u_1 \) is a semigroup word and from Lemma 2.4 otherwise.

We complete the proof of Theorem 1.5. \( \square \)

Theorem 1.5 readily implies the following

**Corollary 4.4.** If a strongly permutative epigroup variety \( \mathcal{V} \) is an upper-modular element of the lattice \( \mathcal{Epi} \) then the lattice \( L(\mathcal{V}) \) is distributive.

**Proof.** If \( \mathcal{V} \) satisfies the claim (i) of Theorem 1.5 then it is periodic, whence it may be considered as a semigroup variety. In this case, it suffices to take into account a description of commutative semigroup varieties with distributive subvariety lattice obtained in [30]. Suppose now that \( \mathcal{V} \) satisfies the claim (ii) of Theorem 1.5. Then \( \mathcal{V} \subseteq \mathcal{AG} \lor \mathcal{C}_2 \lor \mathcal{N} \) where \( \mathcal{N} \) satisfies the commutative law and the identity (1). In view of Proposition 2.10, \( L(\mathcal{V}) \) is embeddable into the direct product of the lattices \( L(\mathcal{AG}) \) and \( L(\mathcal{C}_2 \lor \mathcal{N}) \). The former lattice is generally known to be distributive. Finally, the variety \( \mathcal{C}_2 \lor \mathcal{N} \) is periodic, whence it may be considered as a semigroup variety. To complete the proof, it remains to note that the lattice \( L(\mathcal{C}_2 \lor \mathcal{N}) \) is distributive by the mentioned result of [30]. \( \square \)

## 5. Codistributive varieties

Here we verify Theorem 1.2.

a) \( \rightarrow b) \). Here and in Section 7 we need the following statement that may be verified by repeating literally arguments from the first paragraph of the proof of Theorem 1.1 in [24].

**Lemma 5.1.** Let an epigroup variety \( \mathcal{V} \) be a codistributive element of the lattice \( \mathcal{Epi} \). If \( \mathcal{V} \) does not contain the varieties \( \mathcal{P} \) and \( \mathcal{P}^- \) then \( \mathcal{V} \) is a variety of degree \( \leq 2 \). \( \square \)

Let now \( \mathcal{V} \) be a strongly permutative codistributive variety. It is evident that \( \mathcal{V} \) is upper-modular. Theorem 1.5 implies that the variety \( \mathcal{V} \) is commutative. Hence \( \mathcal{P}, \mathcal{P}^- \notin \mathcal{V} \). It remains to refer to Lemma 5.1.

b) \( \rightarrow c) \). This implication immediately follows from Corollary 2.9 and the observation that the variety \( \mathcal{C}_m \) has a degree \( > 2 \) whenever \( m \geq 2 \).
c) $\rightarrow$ a). In view of Corollary 3.3, it suffices to verify that an abelian group variety $G$ is codistributive. Let $Y$ and $Z$ be arbitrary epigroup varieties. Every epigroup variety is either periodic or contains the variety $AG$. Suppose that at least one of the varieties $Y$ and $Z$, say $Y$, contains $AG$. Then $Y \cup Z \supseteq Y \supseteq AG \supseteq G$ and therefore,

$$G \land (Y \cup Z) = G = G \lor (G \land Z) = (G \lor Y) \lor (G \land Z).$$

Hence we may assume that the varieties $Y$ and $Z$ are periodic. Now we may complete the proof by the same arguments as in the proof of the implication c) $\rightarrow$ a) of Theorem 1.2 in [24].

\[ \square \]

6. Modular varieties

Here we are going to prove Theorems 1.3 and 1.4. We need several auxiliary facts.

**Proposition 6.1.** If an epigroup variety $V$ is a modular element of the lattice Epi then $V$ is periodic.

**Proof.** Let $V$ be a modular epigroup variety. Suppose that $V$ is non-periodic. Being an epigroup variety, $V$ satisfies the identity $x^n = x^n x^\omega$ for some natural $n$. Consider varieties

$$\mathcal{N}_1 = \text{var}\{x_1 x_2 \ldots x_{n+3} = 0\} \text{ and } \mathcal{N}_2 = \text{var}\{x_1 x_2 \ldots x_{n+3} = 0, x^{n+1} y = x^n y^2\}.$$  

To prove that $V$ is non-modular, we are going to check that the varieties $V, \mathcal{N}_1, \mathcal{N}_2, V \cup \mathcal{N}_1$ and $V \land \mathcal{N}_1$ form the 5-element non-modular sublattice $\mathcal{N}_5$. Note that $\mathcal{N}_2 \subseteq \mathcal{N}_1$. Whence, to achieve our aim, it suffices to verify the equalities $V \cup \mathcal{N}_1 = V \cup \mathcal{N}_2$ and $V \land \mathcal{N}_1 = V \land \mathcal{N}_2$.

The inclusion $V \cup \mathcal{N}_2 \subseteq V \cup \mathcal{N}_1$ is evident. It is evident also that a non-trivial identity $u = v$ holds in $\mathcal{N}_2$ if and only if either $\ell(u), \ell(v) \geq n + 3$ or $u = v$ coincides with the identity $x^{n+1} y = x^n y^2$. Let $u = v$ be a non-trivial identity that is satisfied by the variety $V \cup \mathcal{N}_2$. Substituting $y^2$ for $y$ in the identity $x^{n+1} y = x^n y^2$, we have $x^{n+1} y^2 = x^n y^4$ that implies $x^{n+3} = x^{n+4}$. Therefore, a variety satisfying $x^{n+1} y = x^n y^2$ is periodic. Since the identity $u = v$ holds in a non-periodic variety $V$, it differs from the identity $x^{n+1} y = x^n y^2$. Therefore, $\ell(u), \ell(v) \geq n + 3$. This implies that $u = v$ holds in $\mathcal{N}_1$ and therefore, in $V \cup \mathcal{N}_1$. Thus, $V \cup \mathcal{N}_1 \subseteq V \cup \mathcal{N}_2$. The equality $V \cup \mathcal{N}_1 = V \cup \mathcal{N}_2$ is proved.

The inclusion $V \land \mathcal{N}_2 \subseteq V \land \mathcal{N}_1$ is evident. The variety $V \land \mathcal{N}_1$ is a nilvariety and is contained in $V$. Since $V$ satisfies $x^n = x^n x^\omega$, Lemma 2.6(ii) implies that $x^n = 0$ holds in $V \land \mathcal{N}_1$. Therefore, $x^{n+1} y = 0 = x^n y^2$ in $V \land \mathcal{N}_1$. We see that $V \land \mathcal{N}_1 \subseteq \mathcal{N}_2$, whence $V \land \mathcal{N}_1 \subseteq V \land \mathcal{N}_2$. The equality $V \land \mathcal{N}_1 = V \land \mathcal{N}_2$ is proved as well. \[ \square \]

We denote by $\textbf{Per}$ the lattice of all periodic semigroup varieties. It is evident that $\textbf{Per}$ is a sublattice of $\textbf{Epi}$.

**Lemma 6.2.** Let $V$ be a nilvariety that is a modular element of the lattice Epi. If $V$ satisfies a non-substitutive identity $u = v$ then it satisfies also the identity $u = 0$. 

\[ \square \]
Proof. If the identity \( u = v \) is not a semigroup one then Lemma 2.4 is applied with the desirable conclusion. So, we may assume that \( u = v \) is a semigroup identity. Note that the variety \( V \) is periodic, whence it may be considered as a semigroup variety. Clearly, \( V \) is a modular element of the lattice \( \text{Per} \). It is verified in [19, Proposition 2.2] that if a semigroup variety is modular in the lattice \( \text{SEM} \) then it has the property we verify. All varieties that appear in the proof of this claim are periodic. Therefore, the desirable conclusion is true for modular elements of the lattice \( \text{Per} \), and we are done. \( \square \)

The formulation of the following statement and its proof are closely related with the formulation and proof of Lemma 3.1 of the article [11]. But we need slightly modify some terminology from this article. Lemma 3.1 of [11] deals with the notions of equivalent and non-stable pairs of (semigroup) words defined in [11]. Here we need some modification of the first notion and do not require the second one at all. So, we call semigroup words \( u \) and \( v \) equivalent if \( u \equiv \xi(v) \) for some automorphism \( \xi \) on \( F \). Clearly, if words \( u \) and \( v \) are equivalent semigroup words then \( u = v \) is a substitutive identity.

**Lemma 6.3.** Let \( V \) be an epigroup variety that is a modular element of the lattice \( \text{Epi} \) and let \( u, v, s \) and \( t \) be pairwise non-equivalent words of the same length depending on the same letters. If the variety \( V \) satisfies the identities \( u = v \) and \( s = t \) then it satisfies also the identity \( u = s \).

Proof. In view of Proposition 6.1, the variety \( V \) is periodic. Whence, it may be considered as a semigroup variety. Clearly, \( V \) is a modular element of the lattice \( \text{Per} \). The proof of [11, Lemma 3.1] readily implies that if \( u, v, s \) and \( t \) are pairwise non-equivalent words of the same length depending on the same letters, \( V \) satisfies the identities \( u = v \) and \( s = t \) and \( V \) does not satisfy the identity \( u = s \) then there are periodic varieties (in actual fact, even nilvarieties) \( U \) and \( W \) such that \( U \subseteq W \) but \( (V \vee U) \wedge W \neq (V \wedge W) \vee U \). This contradicts the claim that \( V \) is a modular element of the lattice \( \text{Per} \). \( \square \)

**Proof of Theorem 1.3.** Let \( V \) be a modular epigroup variety. According to Proposition 6.1, the variety \( V \) is periodic. It follows immediately from [11, Proposition 3.3] that if a periodic semigroup variety is a modular element of the lattice \( \text{SEM} \) then it is the join of one of the varieties \( T \) or \( SL \) and a nilvariety. Repeating literally arguments from the proof of this statement with references to Proposition 2.7 and Lemma 2.8 of the present work rather than Lemma 2.6 of the article [11] and to Lemma 6.3 of the present work rather than Lemma 3.1 of the article [11], we obtain that the variety \( V \) has the same property. Thus, \( V = M \vee N \) where \( M \) is one of the varieties \( T \) or \( SL \) and \( N \) is a nilvariety. It remains to verify that if \( N \) satisfies a non-substitutive identity \( u = v \) then \( N \) satisfies also the identity \( u = 0 \). If the identity \( u = v \) is not a semigroup one then Lemma 2.4 is applied with the conclusion that \( N \) satisfies the identity \( u = 0 \). So, we may assume that \( u = v \) is a semigroup identity. Note that the variety \( N \) is periodic, whence it may be considered as a semigroup variety. In this situation the desirable conclusion directly follows from [19, Proposition 2.2]. Theorem 1.3 is proved. \( \square \)
Proof of Theorem 1.4. Necessity. Let \( V \) be a commutative modular epigroup variety. By Theorem 1.3 \( V = M \vee N \) where \( M \) is one of the varieties \( T \) or \( SL \) and \( N \) is a nilvariety. Corollary 3.3 implies that the variety \( N \) is modular. Since every commutative variety satisfies the identity \( x^2 y = y x^2 \), Lemma 6.2 implies that the identity (1) holds in \( N \).

Sufficiency. In view of Corollary 3.3, it suffices to verify that a commutative epigroup variety satisfying the identity (1) is modular. This fact may be verified by the same arguments as in the proof of the ‘if’ part of Theorem 1 in [27]. Theorem 1.4 is proved.

7. Neutral and costandard varieties

Here we prove Theorem 1.1. The proof will be given by the following scheme:

\[ \begin{array}{ccc}
\text{a)} & \text{b)} & \text{d)} \\
& \text{c)} & \\
\end{array} \]

The implications \( \text{a)} \rightarrow \text{b)} \) and \( \text{a)} \rightarrow \text{c)} \) are evident, while the implication \( \text{d)} \rightarrow \text{a)} \) immediately follows from Propositions 3.1 and 3.2, and the well-known fact that the set of all neutral elements of a lattice \( L \) forms a sublattice in \( L \) (see [2, Theorem 259 on p. 230]). It remains to verify the implications \( \text{b)} \rightarrow \text{d)} \) and \( \text{c)} \rightarrow \text{d)} \).

\( \text{b)} \rightarrow \text{d)} \). Since the variety \( V \) is modular, we may apply Theorem 1.3 and conclude that \( V = M \vee N \) where \( M \) is one of the varieties \( T \) or \( SL \) and \( N \) is a nilvariety. It remains to verify that \( N \) is one of the varieties \( T \) or \( ZM \). By Lemma 2.18 we have to check that \( N \subseteq ZM \). In other words, we need to verify that \( N \) is a variety of degree \( \leq 2 \). In view of Corollary 3.3, \( N \) is costandard. This evidently implies that \( N \) is codistributive. Clearly, \( N \) does not contain the varieties \( P \) and \( \overline{P} \). Now Lemma 5.1 successfully applies with the conclusion that \( N \) is a variety of degree \( \leq 2 \).

\( \text{c)} \rightarrow \text{d)} \). The variety \( V \) is modular. As in the proof of the previous implication, Theorem 1.3 implies that \( V = M \vee N \) where \( M \) is one of the varieties \( T \) or \( SL \) and \( N \) is a nilvariety, and it suffices to check that \( N \subseteq ZM \). The variety \( V \) is lower-modular and upper-modular. Corollary 3.3 implies that the variety \( N \) is lower-modular and upper-modular too.

A variety is called 0-reduced if it may be given by 0-reduced identities only. One can verify that the variety \( N \) is 0-reduced. Arguing by contradiction, we suppose that this is not the case. The ‘only if’ part of the proof of Theorem 3.1 in [31] implies now that there is a periodic group variety \( G \) such that \( \text{Nil}(G \vee N) \supset N \). Put \( N' = \text{Nil}(G \vee N) \). Since \( N \subseteq N' \) and the variety \( N \) is lower-modular, we have

\[
N' = (G \vee N) \land N' = (G \land N') \lor N = T \lor N = N,
\]

contradicting the claim that \( N \subseteq N' \).
Further, $\mathcal{N}$ is periodic, whence it may be considered as a semigroup variety. Therefore, $\mathcal{N}$ is an upper-modular element of the lattice $\text{Per}$. It follows from [23, Theorem 1] that if a proper semigroup variety of degree $> 2$ is upper-modular in $\text{SEM}$ then it is commutative. All varieties that appear in the proof of this fact are periodic. So, we have that a variety of degree $> 2$ is commutative whenever it is an upper-modular element in $\text{Per}$. In particular, the variety $\mathcal{N}$ is commutative. Thus, $\mathcal{N}$ is a 0-reduced and commutative nilvariety. Therefore, $\mathcal{N} \subseteq \mathcal{ZM}$.

8. Open questions

It was proved in [21, Corollary 3.5] that the following strengthened semigroup analog of the equivalence of the claims a) and c) of Theorem 1.1 is true: a semigroup variety is neutral in $\text{SEM}$ if and only if it is simultaneously lower-modular and upper-modular in $\text{SEM}$. We do not know, whether the epigroup analog of this claim is valid.

Question 8.1. Is it true that an epigroup variety is a neutral element of the lattice $\text{Epi}$ if and only if it is simultaneously a lower-modular and upper-modular element of this lattice?

It is verified in [24, Theorem 1.1] that if a proper semigroup variety $\mathcal{V}$ is codistributive in $\text{SEM}$ then the square of any member of $\mathcal{V}$ is completely regular. We do not know, whether the epigroup analog of this fact is true.

Question 8.2. Is it true that if an epigroup variety $\mathcal{V}$ is a codistributive element of the lattice $\text{Epi}$ then the square of any member of $\mathcal{V}$ is completely regular?

As we have already mentioned in Section 4, it is proved in [22, Theorem 1.1] that if $\mathcal{V}$ is a proper upper-modular in $\text{SEM}$ semigroup variety then every nilsubvariety of $\mathcal{V}$ is commutative and satisfies the identity (2). Proposition 4.2 gives a partial epigroup analog of this assertion. We do not know, whether the full analog is true.

Question 8.3. Suppose that an epigroup variety $\mathcal{V}$ is an upper-modular element of the lattice $\text{Epi}$ and let $\mathcal{N}$ be a nilsubvariety of $\mathcal{V}$. Is it true that $\mathcal{N}$

a) is commutative;

b) satisfies the identity (2)?

Proposition 4.2 shows that the affirmative answer to Question 8.3a) would immediately implies the same answer to Question 8.3b).

Further, it is verified in [23, Theorem 1] that every proper upper-modular in $\text{SEM}$ variety is either commutative or has a degree $\leq 2$. We do not know, whether the epigroup analog of this alternative is valid. We formulate the corresponding question together with its weaker version.

Question 8.4. Suppose that an epigroup variety $\mathcal{V}$ is an upper-modular element of the lattice $\text{Epi}$. Is it true that the variety $\mathcal{V}$

a) either is commutative or has a degree $\leq 2$;

b) either is permutative or has a finite degree?
The affirmative answer to Question 8.4a) together with Theorem 1.5 would immediately imply a complete description of upper-modular epigroup varieties of degree \( > 2 \).

At the conclusion of the article we briefly mention about lower-modular and distributive varieties. It is verified in [20] that every proper lower-modular in SEM variety is periodic\(^2\). The question, whether the epigroup analog of this claim is the case, is open.

**Question 8.5.** *Is it true that if an epigroup variety \( V \) is a lower-modular element of the lattice \( \text{Epi} \) then the variety \( V \) is periodic?*

Lower-modular in SEM varieties were completely determined in [13] (this result is reproved in a simpler way in [11]). Further, it is evident that a distributive element of a lattice is lower-modular. Distributive in SEM varieties were completely classified in [26]. This allows us to hope that the affirmative answer to Question 8.5 would allow to describe lower-modular epigroup varieties and distributive ones.
