In this work we construct 36 tetraquark configurations for the 1S-, 1P-, and 2S-wave states, and make a prediction of the mass spectrum for the tetraquark $ss\bar{s}\bar{s}$ system in the framework of a nonrelativistic potential quark model without the diquark-antidiquark approximation. The model parameters are well determined by our previous study of the strangeonium spectrum. We find that the resonances $f_0(2200)$ and $f_2(2340)$ may favor the assignments of ground states $T_{ss\bar{s}\bar{s}}^{++}(2218)$ and $T_{ss\bar{s}\bar{s}}^{++}(2304)$, respectively, and the newly observed $X(2500)$ at BESIII may be a candidate of the lowest mass 1P-wave $0^+$ state $T_{ss\bar{s}\bar{s}}^{++}(2481)$. Signals for the other $0^+$ ground state $T_{ss\bar{s}\bar{s}}^{++}(2440)$ may also have been observed in the $\phi\phi$ invariant mass spectrum in $J/\psi \to \gamma\phi\phi$ at BESIII. The masses of the $J^{PC}=1^{--}T_{ss\bar{s}\bar{s}}$ states are predicted to be in the range of $\sim 2.44 - 2.99$ GeV, which indicates that the $\phi(2170)$ resonance may not be a good candidate of the $T_{ss\bar{s}\bar{s}}$ state. This study may provide a useful guidance for searching for the $T_{ss\bar{s}\bar{s}}$ states in experiments.

PACS numbers:

I. INTRODUCTION

From the Review of Particle Physics (RPP) of Particle Data Group [1], above the mass range of 2.0 GeV one can see that there are several unflavored $q\bar{q}$ isoscaler states, such as $f_0(2200)$, $f_2(2150)$, $f_2(2300)$, $f_2(2340)$ etc., dominantly decaying into $\phi\phi$, $\eta\eta$, and/or $KK$ final states. The decay modes indicate that these states might be good candidates for conventional $s\bar{s}$ meson resonances. Recently, we carried out a systematical study of the mass spectrum and strong decay properties of the $s\bar{s}$ system in Ref. [2]. It shows that these states cannot be easily accommodated by the conventional $s\bar{s}$ meson spectrum. While they may be candidates for tetraquark $ss\bar{s}\bar{s}$ ($T_{ss\bar{s}\bar{s}}$) states, it is easy to understand that they can fall apart into $\phi\phi$ and $\eta\eta$ final states through quark rearrangements, or easily decay into $KK$ final states through a pair of $s\bar{s}$ annihilations and then a pair of light quark creations. The mass analysis with the relativistic quark model in Ref. [3] supports the $f_0(2200)$, and $f_2(2340)$ to be assigned as the $T_{ss\bar{s}\bar{s}}$ ground states with $0^{++}$ and $2^{++}$, respectively. However, a relativized quark model calculation [4] only favors $f_2(2300)$ to be a $T_{ss\bar{s}\bar{s}}$ state.

Some other candidates of the $T_{ss\bar{s}\bar{s}}$ states from experiment are also suggested in the literature. For example the vector meson resonance $\phi(2170)$ listed in RPP [1] is suggested to be a $1^{--}T_{ss\bar{s}\bar{s}}$ state based on the mass analysis of QCD sum rules [5–9], and flux-tube model [10]. The newly observed $X(2239)$ resonance in the $e^+e^- \to KK$ process at BESIII [11] is suggested to be a candidate of the lowest $1^{--}T_{ss\bar{s}\bar{s}}$ state in a relativized quark model [4]. Moreover, the newly observed resonances $X(2500)$ observed in $J/\psi \to \gamma\phi\phi$ [12] and $X(2060)$ observed in $J/\psi \to \phi\eta\eta'$ at BESIII are suggested to be $0^{++}$ and $1^{--}T_{ss\bar{s}\bar{s}}$ states, respectively, according to the QCD sum rule studies [14, 15]. The assignment of $X(2500)$ is consistent with that in Ref. [4].

With the recent experimental progresses more quantitative studies on the $T_{ss\bar{s}\bar{s}}$ states can be carried out and their evidences can also be searched for in experiments. Very recently, the LHCb Collaboration reported their results on the observations of tetraquark $cc\bar{c}\bar{c}$ ($T_{cc\bar{c}\bar{c}}$) states [16]. A broad structure above the $J/\psi J/\psi$ threshold ranging from 6.2 to 6.8 GeV and a narrower structure $T_{cc\bar{c}\bar{c}}(6900)$ are observed with more than $5\sigma$ of significance level. There are also some vague structure around 7.2 GeV to be confirmed. These observations could be evidences for genuine $T_{cc\bar{c}\bar{c}}$ states [17–21].

The observations of the $T_{cc\bar{c}\bar{c}}$ states above the $J/\psi J/\psi$ threshold at LHCb may provide an important clue for the underlying dynamics for the $cc\bar{c}\bar{c}$ system. In particular, the narrowness of $T_{cc\bar{c}\bar{c}}(6900)$ suggests that there should be more profound mechanism that “slows down” the fall-apart decays of such a tetraquark system. Although this may be related to the properties of the static potential of heavy quark systems, more direct evidences are still needed to disentangle the dynamical features between the heavy and light flavor systems. As an analogy of the $T_{cc\bar{c}\bar{c}}$ system, there might exist stable $T_{ss\bar{s}\bar{s}}$ states above the $\phi\phi$ threshold, and can likely be observed in the di-$\phi$ mass spectrum. On the other hand, flavor mixings could be important for the light flavor systems and pure $ss\bar{s}\bar{s}$ states may not exist. To answer such questions, systematic calculations of the $ss\bar{s}\bar{s}$ system should be carried out. The BESIII experiments can provide a large data sample for the search of the $T_{ss\bar{s}\bar{s}}$ states in $J/\psi$ and $\psi(2S)$ decays.

In theory, although there have been some predictions of the $T_{ss\bar{s}\bar{s}}$ spectrum within the quark model [3, 4, 10] and QCD sum rules [17–20], most of the studies focus on some special states in a diquark-antidiquark picture. About the status of the tetraquark states, some recent review works can be referenced [22, 23]. In this study we intend to provide a systematical calculation of the mass spectrum of the 1S, 1P and
2$S$-wave $T_{s\bar{s}i\bar{s}}$ states without the diquark-antidiquark approximation in a nonrelativistic potential quark model (NRQPM).

The NRQPM is based on the Hamiltonian proposed by the Cornell model [24], which contains a linear confinement and a one-gluon-exchange (OGE) potential for quark-quark and quark-antiquark interactions. With the NRQPM, we have successfully described the $s\bar{s}$, $c\bar{c}$, and $b\bar{b}$ meson spectra [2, 25, 26], and $s$s$s$, $c$c$c$ and $b$b$b$ baryon spectra [27, 28]. Furthermore, we adopted the NRQPM for the study of both $1S$ and $1P$-wave all-heavy tetraquark states with a Gaussian expansion method [21, 29]. In this work we continue to extend this method to study the $T_{s\bar{s}i\bar{s}}$ spectrum by constructing the full tetraquark configurations without the diquark-antidiquark approximation. With the parameters determined in our study of the $s\bar{s}$ spectrum [2], we obtain a relatively reliable prediction of the mass spectrum for $36T_{s\bar{s}i\bar{s}}$ states, i.e., $4$ $1S$-wave ground states, $20$ $1P$-wave orbital excitations, and $12$ $2S$-wave radial excitations.

The paper is organized as follows: a brief introduction to the tetraquark spectrum is given in Sec. II. In Sec. III, the numerical results and discussions are presented. A short summary is given in Sec. IV.

II. MASS SPECTRUM

A. Hamiltonian

We adopt a NRQPM to calculate the mass spectrum of the $s\bar{s}s\bar{s}$ system. In this model the Hamiltonian is given by

$$H = \sum_{i=1}^{4} m_i + T_i - T_G + \sum_{i<j} V_{ij}(r_{ij}),$$

where $m_i$ and $T_i$ stand for the constituent quark mass and kinetic energy of the $i$th quark, respectively; $T_G$ stands for the center-of-mass (c.m.) kinetic energy of the tetraquark system; $r_{ij} \equiv |\mathbf{r}_i - \mathbf{r}_j|$ is the distance between the $i$th and $j$th quark; and $V_{ij}(r_{ij})$ stands for the effective potential between them. In this work the $V_{ij}(r_{ij})$ adopts a widely used form [24–26, 30–36]:

$$V_{ij}(r_{ij}) = V_{ij}^{conf}(r_{ij}) + V_{ij}^{ind}(r_{ij}),$$

where the confinement potential adopts the standard form of the Cornell potential [24], which includes the spin-independent linear confinement potential $V_{ij}^{Lin}(r_{ij}) \propto r_{ij}$ and Coulomb-like potential $V_{ij}^{conf}(r_{ij}) \propto 1/r_{ij}$;

$$V_{ij}^{conf}(r_{ij}) = -\frac{3}{16}(\lambda_i \cdot \lambda_j) \left( b_{ij} r_{ij} - \frac{4}{3} \alpha_{ij} r_{ij} + C_0 \right).$$

The constant $C_0$ stands for the zero point energy. While the spin-dependent potential $V_{ij}^{ind}(r_{ij})$ is the sum of the spin-spin contact hyperfine potential $V_{ij}^{ss}$, the spin-orbit potential $V_{ij}^{so}$, and the tensor term $V_{ij}^{T}$,

$$V_{ij}^{ind}(r_{ij}) = V_{ij}^{ss} + V_{ij}^{T} + V_{ij}^{LS},$$

with

$$V_{ij}^{ss} = -\frac{\alpha_{ij}}{4}(\lambda_i \cdot \lambda_j) \left( \frac{\pi}{2} e^{-\sigma_{ij} r_{ij}} \cdot \frac{16}{3 m_i m_j} (S_i \cdot S_j) \right),$$

$$V_{ij}^{LS} = -\frac{\alpha_{ij}}{16 m_i m_j} \left( L_{ij} \cdot (S_i + S_j) \right)$$

$$- \frac{\alpha_{ij}}{16 m_i m_j} \left( L_{ij} \cdot (S_i - S_j) \right),$$

$$V_{ij}^{T} = -\frac{\alpha_{ij}}{4}(\lambda_i \cdot \lambda_j) \frac{1}{m_i m_j r_{ij}^2} \left( 3(S_i \cdot r_{ij})(S_j \cdot r_{ij}) - r_{ij}^2 S_i \cdot S_j \right).$$

In the above equations, $S_i$ stands for the spin of the $i$th quark, and $L_{ij}$ stands for the relative orbital angular momentum between the $i$th and $j$th quark. If the interaction occurs between two quarks or antiquarks, the $\lambda_i \cdot \lambda_j$ operator is defined as $\lambda_i \cdot \lambda_j \equiv \sum_{a=1}^{8} \lambda_i^a \lambda_j^a$, while if the interaction occurs between a quark and an antiquark, the $\lambda_i \cdot \lambda_j$ operator is defined as $\lambda_i \cdot \lambda_j \equiv \sum_{a=1}^{8} -\lambda_i^a \lambda_j^a$, where $\lambda^a$ is the complex conjugate of the Gell-Mann matrix $\lambda^a$. The parameters $b_{ij}$ and $\alpha_{ij}$ denote the strength of the confinement and strong coupling of the one-gluon-exchange potential, respectively.

The five parameters $m_s, \alpha_{ss}, \sigma_{ss}, b_{ss}$, and $C_0$ have been determined by fitting the mass spectrum of the strangeonium in our previous work [2]. The quark model parameters adopted in this work are collected in the Table I.

B. Configurations classified in the quark model

To calculate the spectroscopy of a $qq\bar{q}\bar{q}$ ($q \in \{s, c, b\}$) system, first we construct the configurations in the product space of flavor, color, spin, and spatial parts.

In the color space, there are two color-singlet bases $|6\bar{6}\rangle_c$ and $|33\rangle_c$, their wave functions are given by

$$|6\bar{6}\rangle_c = \frac{1}{\sqrt{6}} \left[ (rb + br)(\bar{b}r + \bar{r}b) + (gr + rg)(\bar{g}r + \bar{r}g) \right. + (gb + bg)(\bar{g}b + \bar{b}g) \right.$$ (8)

$$+ 2(rr)(\bar{r}\bar{r}) + 2(\bar{g}g)(\bar{g}g) + 2(bb)(\bar{b}b) \right].$$

$$|33\rangle_c = \frac{1}{\sqrt{3}} \left[ (rb - br)(\bar{b}r - \bar{r}b) - (rg - gr)(\bar{g}r - \bar{r}g) \right.$$

$$+ (gb - gb)(\bar{g}b - \bar{b}g) \right].$$

In the spin space, there are six spin bases, which are denoted by $\chi_{ij}^{2s1S4}$. Where $S_2$ stands for the spin quantum numbers for the diquark ($q_1q_2$) (or antidiquark ($\bar{q}_1\bar{q}_2$)), while $S_4$ stands for the spin quantum number for the antidiquark ($\bar{q}_1\bar{q}_2$) (or diquark ($q\bar{q}$)). $S$ is the total spin quantum number of the tetraquark $qq\bar{q}\bar{q}$ system.
TABLE I: Quark model parameters used in this work.

| Parameter | Value |
|-----------|-------|
| $m_i$ (GeV) | 0.60 |
| $\alpha_s$ | 0.77 |
| $\sigma_{ss}$ (GeV) | 0.60 |
| $b$ (GeV$^2$) | 0.135 |
| $C_0$ (GeV) | −0.519 |

a determined $S_z$ ($S_z$ stands for the third component of the total spin $S$) can be explicitly expressed as follows:

$$
\chi_{00} = \frac{1}{2}(\uparrow\uparrow\uparrow - \uparrow\uparrow\downarrow - \downarrow\uparrow\uparrow + \downarrow\uparrow\downarrow),
$$

$$
\chi_{11} = \sqrt{\frac{3}{2}}(2 \uparrow\uparrow\downarrow - \uparrow\uparrow\uparrow - \downarrow\uparrow\downarrow - \uparrow\downarrow\uparrow + \downarrow\uparrow\downarrow + \downarrow\downarrow\uparrow),
$$

$$
\chi_{01} = \sqrt{\frac{3}{2}}(\downarrow\uparrow\uparrow - \uparrow\downarrow\uparrow),
$$

$$
\chi_{10} = \frac{1}{2}(\uparrow\uparrow\uparrow - \uparrow\uparrow\downarrow - \downarrow\uparrow\uparrow - \downarrow\uparrow\downarrow),
$$

$$
\chi_{11} = \frac{1}{2}(\uparrow\uparrow\uparrow - \downarrow\uparrow\uparrow - \downarrow\uparrow\downarrow - \downarrow\downarrow\uparrow),
$$

$$
\chi_{12} = \uparrow\uparrow\uparrow.
$$

In the spatial space, we define the relative Jacobi coordinates with the single-partial coordinates $r_i$ ($i = 1, 2, 3, 4$):

$$
\xi_1 = r_1 - r_2,
$$

$$
\xi_2 = r_3 - r_4,
$$

$$
\xi_3 = \frac{m_1 r_1 + m_2 r_2 - m_3 r_3 - m_4 r_4}{m_1 + m_2 - m_3 - m_4},
$$

$$
R = \frac{m_1 r_1 + m_2 r_2 + m_3 r_3 + m_4 r_4}{m_1 + m_2 + m_3 + m_4}.
$$

Note that $\xi_1$ and $\xi_2$ stand for the relative Jacobi coordinates between two quarks $q_1$ and $q_2$ (or antiquarks $\bar{q}_1$ and $\bar{q}_2$), and two antiquarks $\bar{q}_3$ and $\bar{q}_4$ (or quarks $q_3$ and $q_4$), respectively. While $\xi_3$ stands for the relative Jacobi coordinate between di-quark $qq$ and anti-di-quark $\bar{q}\bar{q}$. Using the above Jacobi coordinates, it is easy to obtain basis functions that have well-defined symmetry under permutations of the pairs (12) and (34) [37].

In the Jacobi coordinate system, the spatial wave function $\Psi_{NLM}(\xi_1, \xi_2, \xi_3, R)$ for a $qq\bar{q}\bar{q}$ system with principal quantum number $N$ and orbital angular momentum quantum numbers $LM$ may be expressed as the linear combination of $\Phi(R)\psi_{a}(\xi_1)\psi_{a}(\xi_2)\psi_{a}(\xi_3)$:

$$
\Psi_{NLM}(\xi_1, \xi_2, \xi_3, R) = \sum_{a_1, a_2, a_3} C_{a_1 a_2 a_3} \Phi(R)\psi_{a}(\xi_1)\psi_{a}(\xi_2)\psi_{a}(\xi_3)_{NLM},
$$

where $C_{a_1 a_2 a_3}$ stands for the combination coefficients, $\Phi(R)$ is the center-of-mass (c.m.) motion wave function. In the quantum number set $a_1 \equiv \{n_\xi, l_\xi, m_\xi\}$, $n_\xi$ is the principal quantum number, $l_\xi$ is the angular momentum, and $m_\xi$ is its third component projection. The wave functions $\psi_{a}(\xi_i)$, which account for the relative motions, can be written as

$$
\psi_{a}(\xi_i) = R_{\xi_i m_\xi}(\xi_i)\phi_{a}(\xi_i),
$$

where $\phi_{a}(\xi_i)$ is the spherical harmonic function, and $R_{\xi_i m_\xi}(\xi_i)$ is the radial part. It is seen that for an excited state, there are three spatial excitation modes corresponding to three independent internal wave functions $\psi_{a}(\xi_i)$ ($i = 1, 2, 3$), which are denoted as $\xi_1$, $\xi_2$, and $\xi_3$, respectively, in the present work. One point should be emphasized that considering the fact that the $ss\bar{s}\bar{s}$ system is composed of equal mass constituent quarks and antiquarks, we adopt a single set of Jacobi coordinates in this study as an approximation. In fact, the four-body wave function describing a scalar $ss\bar{s}\bar{s}$ state contains a small contribution of internal angular momentum. This contribution is neglected in our calculations. To precisely treat an $N$-body system, one can involve several different sets of Jacobi coordinates as those done in Refs. [38–43]; or adopt a single set of Jacobi coordinates $X = (\xi_1, \xi_2, ..., \xi_{N-1})$ with non diagonal Gaussians $e^{-XX^T}$ as those done in Refs. [44–47], where $A$ is a symmetric matrix.

Taking into account the Pauli principle and color confinement for the four-quark system $qq\bar{q}\bar{q}$, we have 4 configurations for the $1S$-wave ground states, 20 configurations for the $1P$-wave orbital excitations, and 12 configurations for the $2S$-wave radial excitations. The spin-parity quantum numbers, notations, and wave functions for these configurations are presented in Table II. With the wave functions for all the configurations, the mass matrix elements of the Hamiltonian can be worked out.

To work out the matrix elements in the coordinate space, we expand the radial part $R_{\xi_i m_\xi}(\xi_i)$ with a series of harmonic oscillator functions [21, 27]:

$$
R_{\xi_i m_\xi}(\xi_i) = \sum_{l_\xi} C_{l_\xi} \phi_{l_\xi}(\omega_{l_\xi}^2 \xi_i),
$$

with

$$
\phi_{l_\xi}(\omega_{l_\xi}^2 \xi_i) = \left(\mu_{\xi_i}^2 \omega_{l_\xi}^2 \right)^{2l_\xi + 1} \frac{\sqrt{2^{2l_\xi+1}(2l_\xi+1)!}}{\sqrt{\pi (2l_\xi+1)!}} \frac{\sqrt{\sqrt{2^{2l_\xi}}}}{\pi \mu_{\xi_i}^2 \omega_{l_\xi}^2} \phi_{l_\xi}(\xi_i) \exp\left(-\frac{\xi_i^2}{2\omega_{l_\xi}^2 \mu_{\xi_i}^2}ight).
$$

where $F(-n_\xi, l_\xi; \frac{1}{2}; \mu_{\xi_i}^2 \omega_{l_\xi}^2 \xi_i^2)$ is the confluent hypergeometric function. It should be pointed out that if there are no radial excitations, the expansion method with harmonic oscillator wave functions are just the same as the Gaussian expansion method adopted in the literature [38, 39].

For an $ss\bar{s}\bar{s}$ system, if we ensure that the spatial wave function with Jacobi coordinates can transform into the single particle coordinate system, the harmonic oscillator frequencies $\omega_{l_\xi}$ ($i = 1, 2, 3$) can be related to the harmonic oscillator stiffness factor $K_{l_\xi}$ with $\omega_{l_\xi} = \sqrt{2K_{l_\xi}/\mu_{\xi_i}}$, and $\omega_{l_\xi} = \sqrt[4]{K_{l_\xi}/\mu_{\xi_i}}$. Considering the reduced masses $\mu_{l_\xi} = \mu_{l_\xi} = m_s/2$, $\mu_{l_\xi} = m_s$ for $T_{ss}$, one has $\omega_{l_\xi} = \omega_{l_\xi}^2 = \omega_{l_\xi}^2 = \sqrt[4]{K_{l_\xi}/m_s}$. It indicates that the harmonic
oscillator frequencies $\omega_{\ell t}$ for $T_{s\bar{s}s\bar{s}}$ are not independent. According to the relation $\omega_{\ell t} = \omega_{\ell t'} = \omega_{\ell t''} = \omega_t$, the expansion of $\prod_{i=1}^{3} R_{\nu_i t_i}(\xi_i)$ can be simplified as

$$
\prod_{i=1}^{3} R_{\nu_i t_i}(\xi_i) = \sum_{\ell} \sum_{\ell'} C_{\ell \ell'} \phi_{\nu_1 t_1}(\omega_{\ell t}, \xi_1) \phi_{\nu_2 t_2}(\omega_{\ell t'}, \xi_2) \phi_{\nu_3 t_3}(\omega_{\ell t''}, \xi_3) \delta_{\ell t} \delta_{\ell t'}
$$

where $n$ is the number of harmonic oscillator functions, and $a$ is the ratio coefficient. There are three parameters $\{d_1, d_n, n\}$ to be determined through the variation method. It is found that with the parameter set $[0.085 \text{ fm}, 3.399 \text{ fm}, 15]$ for the $s\bar{s}s\bar{s}$ system, we can obtain stable solutions. The numerical results should be independent of the parameter $d_1$. To confirm this point, as done in the literature [40–42] we scale the parameter $d_1$ of the basis functions as $d_1 \to \alpha d_1$. The mass of a $T_{s\bar{s}s\bar{s}}$ state should be stable at a resonance energy insensitive to the scaling parameter $\alpha$. As an example, we plot the masses of 12 2$S$-wave $T_{s\bar{s}s\bar{s}}$ configurations as a function of the scaling factor $\alpha$ in Fig. 1. It is found that the numerical results are nearly independent of the scaling factor $\alpha$. The stabilization of other states predicted in this work has also been examined by the same method.

With the mass matrix elements ready for each configuration, the mass of the tetraquark configuration and its spacial wave function can be determined by solving a generalized eigenvalue problem. The details can be found in our previous works [27, 29]. Finally, the physical states can be obtained by diagonalizing the mass matrix of different configurations with the same $J^PC$ numbers.

## III. RESULTS AND DISCUSSIONS

Our predictions of the $T_{s\bar{s}s\bar{s}}$ mass spectrum with the HOEM are given in Table III, where the components of different configurations for a physical state can be seen. For example, the two 0$^{++}$ ground states are mixing states between two different configurations $1S_{0^{-+}}(660)$ and $1S_{0^{-+}}(332)$ due to a strong contribution of the confinement potential to the non-diagonal elements. To see the contributions from each part of the Hamiltonian to the mass of different configurations, we also present our results in Table IV. It is found that both the kinetic energy term $\langle V^K \rangle$ and the linear confinement potential term $\langle V^{Lin} \rangle$ contribute a large positive value to the mass, while the Coulomb type potential $\langle V^{Coul} \rangle$ has a large cancelation with these two terms. The spin-spin interaction term $\langle V^{SS} \rangle$, the tensor potential term $\langle V^T \rangle$, and/or the spin-orbit interaction term $\langle V^{LS} \rangle$ have also sizeable contributions to some configurations. Thus, as a reliable calculation, both the spin-independent and spin-dependent potentials should be reasonably included for the $s\bar{s}s\bar{s}$ system. For clarity, our predicted $T_{s\bar{s}s\bar{s}}$ spectrum is plotted in Fig. 2.

### A. Discussions of the numerical method

Herein we discuss the differences of numerical results between the expansion method with the harmonic oscillator wave functions (HOEM) used in present work and the Gaussian expansion method (GEM) often adopted in the literature. For the 1$S$-, 1$P$-wave $T_{s\bar{s}s\bar{s}}$ states, etc., there are no radial excitations. Thus, the GEM is the same as the HOEM. For the first radial excited 2$S$-wave $T_{s\bar{s}s\bar{s}}$ states, the HOEM is different from the GEM because the trail harmonic oscillator wave functions are different from the Gaussian functions.

To see the differences between the two expansion methods we also give our predictions of the 2$S$-wave $T_{s\bar{s}s\bar{s}}$ states based on the GEM. It should be mentioned that by fully expanding $\prod_{i=1}^{3} R_{\nu_i t_i}(\xi_i)$ with the GEM, one cannot distinguish
the \( \xi_1 \) and \( \xi_2 \) excited modes which are defined for the 2S configurations presented in Table II. Then we cannot numerically work out the masses for the following states of 0\(^+\)\((2^1S_0\rightarrow(\bar{d}0,\xi_1,\xi_2)\) and \(2^1S_{0\rightarrow(\bar{d}0,\xi_1,\xi_2)}\), \(1^+\)\((2^1S_{1\rightarrow(33),\xi_1,\xi_2)}\), \(2^+\)\((2^3S_{2\rightarrow(33),\xi_1,\xi_2)}\), and \(2^-\)\((2^5S_{2\rightarrow(33),\xi_1,\xi_2)}\) listed in Table II. To overcome this problem, the spatial wave functions containing the radial excitations are expanded with the Gaussian functions, while the spatial wave functions containing no excitations are adopted

| \(J^P(C)\) | Configuration | Wave Function |
|---------|---------------|---------------|
| \(0^+\) | \(1^1S_{0\rightarrow(\bar{d}0,\xi_1,\xi_2)}\) | \(\psi_{000\chi_{00}}^{00}\) |
| \(0^+\) | \(1^1S_{0\rightarrow(\bar{d}0,\xi_1,\xi_2)}\) | \(\psi_{000\chi_{11}}^{11}\) |
| \(1^+\) | \(1^1S_{1\rightarrow(33),\xi_1,\xi_2)}\) | \(\psi_{000\chi_{11}}^{11}\) |
| \(2^+\) | \(1^3S_{2\rightarrow(33),\xi_1,\xi_2)}\) | \(\psi_{000\chi_{22}}^{22}\) |
| \(0^+\) | \(1^3P_{0\rightarrow(\bar{d}0,\xi_1,\xi_2)}\) | \(\psi_{010\chi_{10}}^{10}\) |
| \(0^+\) | \(1^3P_{0\rightarrow(\bar{d}0,\xi_1,\xi_2)}\) | \(\psi_{010\chi_{11}}^{11}\) |
| \(0^+\) | \(1^3P_{0\rightarrow(\bar{d}0,\xi_1,\xi_2)}\) | \(\psi_{010\chi_{20}}^{20}\) |
| \(1^+\) | \(1^3P_{1\rightarrow(33),\xi_1,\xi_2)}\) | \(\psi_{010\chi_{20}}^{20}\) |
| \(1^+\) | \(1^3P_{1\rightarrow(33),\xi_1,\xi_2)}\) | \(\psi_{010\chi_{22}}^{22}\) |
| \(2^+\) | \(1^3P_{2\rightarrow(33),\xi_1,\xi_2)}\) | \(\psi_{010\chi_{22}}^{22}\) |
the single Gaussian function as an approximation. We have
tested the single Gaussian approximation in the calculations of
the ground 1S \(T_{(ss\bar{s})}\) states, the numerical values are reason-
ably consistent with those calculated with a series of Gaussian
functions. The differences of the numerical results between
these two methods are about 10 MeV.

Our numerical results for the 2S-wave \(T_{(ss\bar{s})}\) states with
the GEM are listed in Table IV and Table V. From Table IV,
it is found that the numerical values for the 0\(^{-}\) configuration
\(2\,1\,S\,0^{+}\,(666,\ell_{1},\ell_{2})\) and 0\(^{+}\) configuration \(2\,1\,S\,0^{+}\,(666,\ell_{1},\ell_{2})\) cal-
culated with the HOEM are significantly different from those
obtained with the GEM. For these two configurations, the pre-
dicted mass differences by the HOEM and GEM can reach up
to \(\sim 70\) MeV. However, for the other 2S-wave \(T_{(ss\bar{s})}\) configu-
rations the numerical values of these two methods are compar-
able with each other. The differences of the predicted masses
between these two methods are about \(10 \text{ -- } 20\) MeV. It should
be mentioned that the Coulomb type potential \(V_{\text{Coul}}\) for the
2S-wave states seems to be sensitive to the numerical methods
as shown in Table IV.

### Table III: Predicted mass spectrum for the \(s\bar{s}s\bar{s}\) system with the HOEM.

| \(J^{PC}\) | Configuration | \((H)\) (MeV) | Mass (MeV) | Eigenvector |
|----------|---------------|---------------|------------|-------------|

TABLE IV: The average contributions of each part of the Hamiltonian to the $s\overline{s}s\overline{s}$ configurations with the HOEM. $(T)$ stands for the contribution of the kinetic energy term. $(V^{Lin})$ and $(V^{Coul})$ stand for the contributions from the linear confinement potential and Coulomb type potential, respectively. $(V^{SS})$, $(V^T)$, and $(V^{LS})$ stand for the contributions from the spin-spin interaction term, the tensor potential term, and the spin-orbit interaction term, respectively. The second number in every column is calculated with the GEM.

| $J^{(NC)}$ Configuration | Mass  | $(T)$  | $(V^{Lin})$ | $(V^{Coul})$ | $(V^{SS})$ | $(V^T)$  | $(V^{LS})$ |

In brief, most of the predictions are consistent with each other between the HOEM and GEM. The uncertainties from the numerical methods do not change our main predictions of the \( T_{ss\bar{s}s} \) spectrum. Although some numerical results for the \( J^{PC} = 0^- \) and \( 0^{++} \) \( 2S \) states show a significant numerical method dependence (See Fig. 2), the GEM may give a slightly more accurate numerical result based on our tests of the charmonium spectrum. In the following, our discussions of the \( 2S \) states are based on the GEM calculations.

### TABLE V: Predicted mass spectrum for the \( 2S \)-wave \( ss\bar{s}\bar{s} \) system with the GEM.

| \( J^{PC} \) | Configuration | \( \langle H \rangle \) (MeV) | Mass (MeV) | Eigenvector |
|-------------|---------------|-----------------|----------|-------------|
| 0^-         | \( 2S_{0^-}^{1s}(6s^3,4s) \) | \( \begin{pmatrix} 2927 & 38 \\ 38 & 2931 \end{pmatrix} \) | \( 2891 \) | \( -0.73 \) | \( 0.69 \) |
|             | \( 2S_{0^-}^{1s}(3s^3,4s) \) | \( \begin{pmatrix} 2874 & -48 & 27 & -24 \\ -48 & 2918 & -8 & -42 \end{pmatrix} \) | \( 2798 \) | \( -0.50 \) | \( -0.46 \) | \( -0.04 \) | \( -0.73 \) |
| 0^+         | \( 2S_{0^+}^{1s}(6s^3,4s) \) | \( \begin{pmatrix} 27 & -8 & 3148 & -31 \end{pmatrix} \) | \( 2954 \) | \( 0.43 \) | \( -0.87 \) | \( -0.06 \) | \( 0.25 \) |
|             | \( 2S_{0^+}^{2s}(3s^3,4s) \) | \( \begin{pmatrix} -24 & -42 & -31 \end{pmatrix} \) | \( 2841 \) | \( 3155 \) | \( -0.11 \) | \( 0.04 \) | \( -0.09 \) | \( 0.10 \) |
| 1^-         | \( 2S_{1^-}^{1s}(3s^3,4s) \) | \( \begin{pmatrix} 2934 & -40 \\ -40 & 2851 \end{pmatrix} \) | \( 2835 \) | \( -0.38 \) | \( -0.93 \) |
|             | \( 2S_{1^-}^{1s}(3s^3,4s) \) | | \( 2950 \) | \( -0.93 \) | \( 0.38 \) |
| 1^+         | \( 2S_{1^+}^{1s}(3s^3,4s) \) | \( \begin{pmatrix} 2943 \end{pmatrix} \) | \( 2943 \) | 1 |
| 2^-         | \( 2S_{2^-}^{1s}(3s^3,4s) \) | \( \begin{pmatrix} 2965 \end{pmatrix} \) | \( 2965 \) | 1 |
| 2^+         | \( 2S_{2^+}^{1s}(3s^3,4s) \) | \( \begin{pmatrix} 2964 & -43 \\ -43 & 2871 \end{pmatrix} \) | \( 2854 \) | \( -0.36 \) | \( -0.93 \) |
|             | \( 2S_{2^+}^{2s}(3s^3,4s) \) | | \( 2981 \) | \( -0.93 \) | \( 0.36 \) |

### B. \( S \)-wave states

There are four \( 1S \)-wave \( T_{ss\bar{s}s} \) states with \( J^{PC} = 0^{++}, 1^{-+}, 2^{++} \) in the quark model. Their masses are predicted to be in the range of 2.21 – 2.44 GeV. In contrast, the \( 2S \) wave includes twelve states. Except for the highest mass state \( T_{ss\bar{s}s}^{0^{++}} \) (3155), their masses lie in a relative narrow range of 2.78 – 2.98 GeV. Apart from the conventional quantum numbers, i.e., \( J^{PC} = 0^{++}, 1^{-+}, 1^{++}, 2^{++} \), the \( 2S \)-wave can access
exotic quantum numbers, i.e., $J^{PC} = 0^{+-}, 2^{+-}$.

1. 0$^+$ states

In the 1$S$-wave multiplets, the two 0$^{++}$ ground states include $T_{(3\bar{s}3\bar{s})^0}$ (2218) and $T_{(3\bar{s}3\bar{s})^0}$ (2440). Their mass splitting reaches up to about 200 MeV. These two states have a strong mixing between the two color structures $|\bar{6}6\rangle_c$ and $|\bar{3}3\rangle_c$. Their masses are much larger than the mass threshold of $\phi\phi$. Thus, they may easily decay into $\phi\phi$ pair through quark rearrangements. The mass of the lowest 0$^{++}$ $T_{\Xi\Xi}$ in our model is close to the prediction of 2203 MeV in the relativistic diquark-antidiquark model [3]. However, it turns out to be much higher than the predicted value 1716 MeV by the relativized quark model with a diquark-antidiquark approximation [4]. There might be some crucial dynamics missing in the diquark-antidiquark approximation. As a test of the diquark-antidiquark approximation we adopt the approximation as done in Ref. [4] and calculate the mass of the 0$^{++}$ $T_{\Xi\Xi}$ state with the same potential model parameters. We obtain a mass of 1758 MeV, which is comparable with the prediction of Ref. [4], but is obviously smaller than the results without the diquark-antidiquark approximation.

In the 2$S$-wave sector, there are four 0$^{++}$ states, $T_{(3\bar{s}3\bar{s})^0}$ (2798), $T_{(3\bar{s}3\bar{s})^0}$ (2876), $T_{(3\bar{s}3\bar{s})^0}$ (2954), and $T_{(3\bar{s}3\bar{s})^0}$ (3155), predicted in the NRQPM with GEM. A strong mixing between the two color structures $|\bar{6}6\rangle_c$ and $|\bar{3}3\rangle_c$ is also found among these states. In particular, the radial excitation modes ($\xi_1, \xi_2$) and ($\xi_3$) strongly mix with each other. The highest state $T_{(3\bar{s}3\bar{s})^0}$ (3155) leads to a rather large mass gap $\Delta \approx 201$ MeV from the nearby $T_{(3\bar{s}3\bar{s})^0}$ (2954). These 2$S$-wave 0$^{++}$ ss$s$ states may easily decay into $\phi\phi$, $\phi(1680)$ final states through quark rearrangements. They may also easily decay into $K^0\bar{K}^0$ and $K^+K^-$ final states through the $s\bar{s}$ annihilation and a pair of nonstrange $q\bar{q}$ creation. One also notices that these states may directly decay into $\Xi\Xi$ baryon pair with a light $q\bar{q}$ pair creation.

Some evidences for $T_{(3\bar{s}3\bar{s})^0}$ (2218) and $T_{(3\bar{s}3\bar{s})^0}$ (2440) may have been seen in the previous experiments. Recently, Kozielnikov carried out a dynamical analysis of the resonance contributions to $J/\psi \rightarrow \gamma X \rightarrow \gamma \phi\phi$ [48] with the data from BESIII [12]. Two 0$^{++}$ resonances with masses at ~ 2.2 GeV and ~ 2.4 GeV, were extracted from the data. Evidence for a scalar around 2.2 GeV in the $\phi\phi$ mass spectra in $B^0 \rightarrow J/\psi \phi\phi$ [49] was also reported by Ref. [50]. Considering the mass and decay mode, these two scalar structures may be good candidates for $T_{(3\bar{s}3\bar{s})^0}$ (2218) and $T_{(3\bar{s}3\bar{s})^0}$ (2440).

It should be mentioned that $f_2(2200)$ is listed in RPP [1] as a well-established state. It has been seen in the $K^0\bar{K}^0$, $K^+K^-$ and $\eta\eta$, and may be assigned to $T_{(3\bar{s}3\bar{s})^0}$ (2218). Some qualitative features can be expected: (i) The 0$^{++}$ $T_{\Xi\Xi}$ state can decay into $\eta\eta$, $\eta'\eta'$, and $\eta\eta'$ through quark rearrangements via the $s\bar{s}$ component in the $\eta$ and $\eta'$ mesons. An approximate branching ratio fraction can be examined: $BR(\eta\eta) : BR(\eta'\eta') : BR(\eta\eta') \approx \sin^4 \alpha_p : \cos^4 \alpha_p : 2 \sin^2 \alpha_p \cos^2 \alpha_p \approx 0.24 : 0.25 : 0.50$, with $\alpha_p \equiv \arctan \sqrt{2} + \theta_p \approx 44.7^\circ$ without including the phase space factors. (ii) The 0$^{++}$ states may also easily decay into $K^0\bar{K}^0$ and $K^+K^-$ final states through annihilating a pair of $s\bar{s}$ and creating a pair of light $q\bar{q}$. (iii) It is interesting to note that no conventional 0$^{++}$ ss states are predicted around 2.2 GeV in most literatures [2].

To establish the 0$^{++}$ ground states $T_{(3\bar{s}3\bar{s})^0}$ (2218) and $T_{(3\bar{s}3\bar{s})^0}$ (2440), a combined study of decay channels, such as $\phi\phi$, $K^0\bar{K}^0$, $K^+K^-$, $\eta\eta$, $\eta'\eta'$, and $\eta\eta'$, should be necessary. The 2$S$-wave 0$^{++}$ states can be probed in these meson pair decay channels including higher channels such as $\phi\phi(1680)$, and some baryon pair decay channels such as $\Xi\Xi$.

2. 2$^+$ states

There is only one 2$^+$ state $T_{(3\bar{s}3\bar{s})^2}$ (2378) in the 1$S$-wave states. This state lies between the two 0$^{++}$ ground states, and has a pure $|\bar{3}3\rangle_c$ color structure. $T_{(3\bar{s}3\bar{s})^2}$ (2378) may have large decay rates into the $\phi\phi$, $\eta\eta'$ and $\eta'\eta'$ final states through quark rearrangements, and/or into $K^{(*)}\bar{K}^{(*)}$ final states through the annihilation of $s\bar{s}$ and creation of a pair of nonstrange $q\bar{q}$. It should be mentioned that with the diquark-antidiquark approximation, the mass of the 2$^+$ state is predicted to be 2192 MeV, which is about 200 MeV lower than the four-body calculation results.

The $f_2(2340)$ resonance listed in RPP [1] may be assigned to $T_{(3\bar{s}3\bar{s})^2}$ (2378). Besides the measured mass 2345$^{+50}_{-40}$ MeV, the observed decay modes $\phi\phi$ and $\eta\eta'$ are consistent with the expectation of the tetraquark scenario. On the other hand, as a conventional ss state the $f_2(2340)$ cannot be easily accommodated by the quark model expectation [2]. The relativistic quark model calculation of Ref. [3] also supports the $f_2(2340)$ to be assigned as the $T_{\Xi\Xi}$ ground state with 2$^+$. To confirm this assignment, the other main decay modes of $T_{(3\bar{s}3\bar{s})^2}$ (2378) such as $\eta'\eta'$, $\eta'\eta'$, $K^{(*)}\bar{K}^{(*)}$ should be investigated in experiment.

For the 2$S$-wave sector, there are two 2$^+$ ss$s$ states $T_{(3\bar{s}3\bar{s})^2}$ (2854) and $T_{(3\bar{s}3\bar{s})^2}$ (2981) predicted in our model, which are dominated by the $5^S_2^{2++}(\bar{3}3\bar{3}3\bar{3})$ and $5^S_2^{2++}(\bar{3}3\bar{3}3\bar{3})$ configurations, respectively. Their masses are predicted to be above the thresholds of $\phi\phi$, $\phi(1680)$ and $\Xi(1530)\Xi$. Therefore, experimental search for their signals in these decay channels should be helpful for understanding these tensor tetraquarks.

3. 1$^+$ states

In the 1$S$-wave multiplets $T_{(3\bar{s}3\bar{s})^1}$ (2323) is the only state with $C = -1$, and has a pure $|\bar{3}3\rangle_c$ color structure. Its mass is about 100 MeV larger than the lowest 1$S$-wave state $T_{(3\bar{s}3\bar{s})^0}$ (2218). Its mass is about 200 ~ 300 MeV larger than that predicted by the QCD sum rules [15] and the relativized quark model [4] in the diquark picture. The mass of the 1$^+$ state may be notably underestimated in the diquark picture.
As a comparison we calculate the mass of the $1^{--}$ state in the diquark picture using the same potential model parameter set adopted in present work, and obtain a mass of 1936 MeV, which is 300 MeV smaller than the NRQPM prediction 2236 MeV.

$T_{(ssj)}^{1^{--}}$ (2323) may easily decay into $\eta\phi$ and $\eta'\phi$ through the quark rearrangements. The decay of $\psi'/J/\psi \to \phi\eta'\eta$ can access this state in $\eta\phi$ and $\eta'\phi$ channels. It should be mentioned that some hints of $T_{(ssj)}^{1^{--}}$ (2323) may have been found in the $\eta'\phi$ invariant mass spectrum around 2.3 – 2.4 GeV by observing the $J/\psi \to \phi\eta'\eta$ reaction at BESIII recently [13].

For the $2S$-wave sector, there are two states, i.e. $1^{--} ss\bar{s}\bar{s}$ $T_{(ssj)}^{1^{--}}$ (2835) and $T_{(ssj)}^{1^{--}}$ (2950), predicted in the quark model. There are sizeable configuration mixings in these two states. The $T_{(ssj)}^{1^{--}}$ (2835) is dominated by the $3S1^{--}(33)^c$ configuration, which has a $[33]^c$ color structure, and the radial excitation occurs between diquark ($ss$) and anti-diquark ($\bar{s}\bar{s}$) (i.e., the $\xi$ mode). The $T_{(ssj)}^{1^{--}}$ (2950) is dominated by the $3S1^{--}(33,\xi)_{\bar{c}}$ configuration, whose radial excitation occurs in the diquark ($ss$) and anti-diquark ($\bar{s}\bar{s}$). Apart from the $\eta\phi$ and $\eta'\phi$ decay channels they may favor decays into a pseudoscalar plus a radially excited vector (i.e., $\eta(1680)$ and $\eta'(1680)$), or a radially excited pseudoscalar plus a vector (i.e., $\eta(1295)\phi$ and $\eta(1405)\phi$), through the quark rearrangements.

It should be mentioned that in Refs. [9, 15] the authors suggest that the new structure $X(2063)$ observed in the $J/\psi \to \phi\eta'\eta'$ at BESIII [13] could be a $1^{--}$ $T_{ssJ}$ Candidate according to the QCD sum rule calculation. However, the observed mass of $X(2063)$ is too small to be comparable with the quark model predictions.

4. $0^{++}$ and $2^{++}$ states

In the $2S$-wave multiplets, there are two $0^{++}$ states, $T_{(ssj)}^{0^{++}}$ (2891) and $T_{(ssj)}^{0^{++}}$ (2967), predicted in the NRQPM with GEM. There is a strong configuration mixing between $1S0^{++}(60\bar{b}\bar{b}(\xi,\xi))$ and $1S0^{++}(33,\xi,\xi)$. There is only one $2^{++}$ state $T_{(ssj)}^{2^{++}}$ (2965) corresponding to the configuration $5S2^{++}(33,\xi,\xi)$. The $0^{++}$ and $2^{++}$ are exotic quantum numbers which cannot be accommodated by the conventional $q\bar{q}$ scenario. The $P$-wave decays into the $\eta h_1(1P)$ and $\eta' h_1(1P)$ channels could be useful for the search for these states in experiments.

C. $1P$-wave states

There are twenty $1P$-wave $T_{ssJ}$ states predicted in the NRQPM. Apart from the conventional quantum numbers, i.e., $J^{PC} = 0^{++}$, $1^{--}$, $2^{--}$, $2^{++}$, $3^{--}$, the $P$-wave can access exotic quantum numbers, i.e., $J^{PC} = 0^{--}$, $1^{++}$. The masses of the $1P$-wave $T_{ssJ}$ states scatter in a wide range of about 2.4 – 3.0 GeV. The masses of the low-lying $1P$-wave states may highly overlap with the heaviest $1S$-wave state $T_{(ssj)}^{1^{--}}$ (2440).
and BESIII [59], which could be signals of the 1− ssππ tetraquark states [60]. For the heavier states T_{(ss)2} (2657) and T_{(ss)2} (2784), they can also decay into ΣΣ baryon pair through a 1q pair production in vacuum. Thus, experimental search for these states in $e^+e^- \rightarrow ΣΣ$ should be very interesting.

3. 1+ states

There are three 1+ states, T_{(ss)1} (2564), T_{(ss)1} (2632), and T_{(ss)1} (2778), predicted in the NRPQM. Note that 1+ are exotic quantum numbers which cannot be accommodated by the conventional qg scenario. Both the lowest mass state T_{(ss)1} (2564) and highest mass state T_{(ss)1} (2778) are mixed states between the two color structures |66⟩_c and |33⟩_c, and their orbital excitations are dominated by the (η_1, η_2) mode. The middle state T_{(ss)1} (2632) is dominated by the 3P_{1−} configuration of which the orbital excitation mainly occurs between the diquark (ss) and anti-diquark (¯ss). It should be noted that a corresponding state in the relativized quark model [4] has a mass of 2581 MeV, which is about 50 MeV smaller than our prediction.

These 1+ T_{(ss)1} states may easily decay into $ϕ_1 (1400)$, $η′ f_1 (1420)$, $ϕ$ through the quark rearrangements. They can be searched for in $χ_{cJ} (1P) \rightarrow ϕϕ$, $ϕK^−K^+$ with sufficient $χ_{cJ} (1P)$ data samples at BESIII, although no obvious structures were found in previous observations [61, 62].

4. 2+ states

There are three 2+ states, T_{(ss)2} (2537), T_{(ss)2} (2669), and T_{(ss)2} (2837), predicted in the NRPQM. Both the lowest mass state T_{(ss)2} (2537) and highest mass state T_{(ss)2} (2837) are mixed states between the two color structures |66⟩_c and |33⟩_c. Their orbital excitations are dominated by the (ξ_1, ξ_2) mode. The middle state T_{(ss)2} (2669) is dominated by the 3P_{2−} configuration of which the orbital excitation occurs between the diquark (ss) and anti-diquark (¯ss). A corresponding state in the relativized quark model [4] has a mass of 2619 MeV, which is about 50 MeV smaller than our prediction.

These 2+ T_{(ss)2} states may easily fall apart into $ϕ_1 (1P)$ and $η′ f_2 (1525)$ in an S wave, or into $ϕ$ in a P wave through the quark rearrangements. For the high mass state T_{(ss)2} (2837), the strong decay mode ΣΣ also opens. These states can be searched for in $χ_{c2} (1P) \rightarrow η T_{(ss)2} \rightarrow ηη f_2 (1525) \rightarrow ηη K K$ at BESIII with the sufficient $χ_{c2} (1P)$ data samples.

5. 0− states

There are two states with exotic quantum numbers of 0−, T_{(ss)0} (2507) and T_{(ss)0} (2821), predicted in the NRPQM. These two states have a strong mixing between the two color structures |66⟩_c and |33⟩_c. The orbital excitation is the (ξ_1, ξ_2) mode, i.e., the excitation occurs within the diquark (ss) or anti-diquark (¯ss). These two states may have large decay rates into $ϕ_1 (1285)$ and $ϕ_1 (1420)$ in an S wave, or into $ηϕ$ and $η′ϕ$ in a P wave through the quark rearrangements. These 0− exotic states may be produced by the reactions $e^+e^- \rightarrow η′ X \rightarrow η′ η′ ϕ$ or $J/ψ \rightarrow η′ η′ ϕ$.

6. 2− states

There are three 2− states, T_{(ss)2} (2446), T_{(ss)2} (2657), and T_{(ss)2} (2907), predicted in the NRPQM. Both the lowest mass state T_{(ss)2} (2446) and highest mass state T_{(ss)2} (2907) are mixed states between the two color structures, |66⟩_c and |33⟩_c, and their orbital excitations are dominated by the (η_1, η_2) mode. The middle state T_{(ss)2} (2657) is dominated by the 3P_{2−} configuration of which the orbital excitation occurs between the diquark (ss) and anti-diquark (¯ss). A corresponding state in the relativized quark model [4] has a mass of 2622 MeV, which is consistent with our prediction. These 2− states may easily decay into $ϕ_1 (1285)$, $ϕ_1 (1420)$, and $ϕ_1 (1525)$ in an S wave, or into $ηϕ$, $η′ϕ$ in a P wave through the quark rearrangements. They can also be searched for in $e^+e^- \rightarrow η′ X \rightarrow η′ η′ ϕ$ or vector charmonium decays such as $J/ψ \rightarrow η′ ϕ$.

7. 3− state

There is only one 3− state T_{(ss)3} (2719) predicted in the NRPQM. This state has a pure color structure |33⟩_c, and also a pure orbital excitation between the diquark (ss) and anti-diquark (¯ss). Our predicted mass is about 60 MeV larger than that predicted by the relativized quark model [4] with a diquark approximation. The 3− states may easily decay into $ϕ_1 (1525)$ in an S wave by the quark rearrangements. Since it has a high spin, it may be produced relatively easier in p¯p or pp collisions.

IV. SUMMARY

In this work we calculate the mass spectra for the 1S, 1P and 2S-wave T_{(ss)J} states in a nonrelativistic potential quark model without the often-adopted diquark-antidiquark approximation. The 1S-wave ground states lie in the mass range of ~ 2.21 - 2.44 GeV, while the 1P- and 2S-wave states scatter in a rather wide mass range of ~ 2.44 - 2.99 GeV. For the 2S-wave states, except for the highest state T_{(ss)2} (3155) all the other states lie in a relatively narrow range of ~ 2.78 - 2.98 GeV. We find that most of the physical states are mixed states with different configurations.

For the ssππ system it shows that both the kinetic energy (T) and the linear confinement potential (V^{Lin}) contribute a large positive value to the mass, while the Coulomb type potential (V^{Coul}) has a large cancellation with the these two terms. The spin-spin interaction (V^{S5}), tensor potential (V^{T}), and/or the
spin-orbit interaction term \(\langle \tilde{s}s T^SlS \rangle\) also have sizeable contributions to some configurations.

Some \(T_{ss\bar{s}\bar{s}}\) states may have shown hints in experiment. For instance, the observed decay modes and masses of \(f_0(2200)\) and \(f_2(2340)\) listed in RPP [1] could be good candidates for the ground states \(T_{ss\bar{s}\bar{s}}0^+\) (2218) and \(T_{ss\bar{s}\bar{s}}1^+\) (2378), respectively. The newly observed \(X(2500)\) at BESIII may be a candidate for the lowest mass \(1P^+\)-wave 0\(^+\) state \(T_{ss\bar{s}\bar{s}}0^+\) (2481). Another 0\(^+\) ground state \(T_{ss\bar{s}\bar{s}}0^+\) (2440) may have shown signals in the \(\phi\phi\) channel at BESIII [12, 48]. Our calculation shows that \(\phi(2170)\) may not favor a vector state of \(T_{ss\bar{s}\bar{s}}\), because of the much higher mass obtained in our model.

It should be stressed that as a flavor partner of \(T_{c\bar{c}c\bar{c}}\), the \(T_{ss\bar{s}\bar{s}}\) system may have very different dynamic features that need further studies. One crucial point is that the strange quark is rather light and the light flavor mixing effects could become non-negligible. It suggests that strong couplings between \(T_{ss\bar{s}\bar{s}}\) and open strangeness channels could be sizeable. As a consequence, mixings between \(T_{ss\bar{s}\bar{s}}\) and \(T_{s\bar{s}g\bar{g}}\) would be inevitable. For an \(S\)-wave strong coupling, it may also lead to configuration mixings which can be interpreted as hadronic molecules for a near-threshold structure. In such a sense, this study can set up a reference on the basis of orthogonal states. More elaborated dynamics can be investigated by including the hadron interactions in the Hamiltonian. For states with exotic quantum numbers, experimental searches for their signals can be carried out at BESIII and Belle-II.
