Moment Varieties of Gaussian Mixtures

Carlos Améndola, Jean-Charles Faugère, and Bernd Sturmfels

Abstract
The points of a moment variety are the vectors of all moments up to some order of a family of probability distributions. We study this variety for mixtures of Gaussians. Following up on Pearson’s classical work from 1894, we apply current tools from computational algebra to recover the parameters from the moments. Our moment varieties extend objects familiar to algebraic geometers. For instance, the secant varieties of Veronese varieties are the loci obtained by setting all covariance matrices to zero. We compute the ideals of the 5-dimensional moment varieties representing mixtures of two univariate Gaussians, and we offer a comparison to the maximum likelihood approach.

1 Introduction
The $n$-dimensional Gaussian distribution is defined by the moment generating function

$$
\sum_{i_1,i_2,\ldots,i_n \geq 0} \frac{m_{i_1i_2\cdots i_n}}{i_1!i_2!\cdots i_n!} t_1^{i_1}t_2^{i_2}\cdots t_n^{i_n} = \exp(t_1\mu_1 + \cdots + t_n\mu_n) \cdot \exp\left(\frac{1}{2} \sum_{i,j=1}^{n} \sigma_{ij}t_it_j\right).
$$

The model parameters are the entries of the mean $\mu = (\mu_1, \ldots, \mu_n)$ and of the covariance matrix $\Sigma = (\sigma_{ij})$. The unknowns $\mu_i$ have degree 1, and the unknowns $\sigma_{ij}$ have degree 2. Then $m_{i_1i_2\cdots i_n}$ is a homogeneous polynomial of degree $i_1+i_2+\cdots+i_n$ in the $n + \binom{n+1}{2}$ unknowns.

Let $\mathbb{P}^N$ be the projective space of dimension $N = \binom{n+d}{d} - 1$ whose coordinates are all $N+1$ moments $m_{i_1i_2\cdots i_n}$ with $i_1+i_2+\cdots+i_n \leq d$. The closure of the image of parametrization (1) is a subvariety $G_{n,d}$ of $\mathbb{P}^N$. We called this the Gaussian moment variety of order $d$. Its dimension equals $n + \binom{n+1}{2}$. In Section 2 we discuss this variety and its defining polynomials.

The main object of study in this paper is the secant variety $\sigma_k(G_{n,d})$ of the Gaussian moment variety. That variety is the Zariski closure of the set of vectors of moments of order $\leq d$ of any distribution on $\mathbb{R}^n$ that is the mixture of $k$ Gaussians, for $k = 2, 3, \ldots$. In short, $\sigma_k(G_{n,d})$ is the projective variety that represents mixtures of $k$ Gaussians. Since such mixtures are identifiable [11], this secant variety eventually has the expected dimension:

$$
\dim(\sigma_k(G_{n,d})) = k \cdot \left[n + \binom{n+1}{2}\right] + k - 1 \quad \text{for } d \gg 0.
$$

The parametrization of $\sigma_k(G_{n,d})$ is given by replacing the right hand side of (1) with a convex combination of $k$ such expressions. The number of model parameters is the right hand side
of \( \sigma \). If the moments \( m_{i_1i_2\ldots i_n} \) are derived numerically from data, then one obtains a system of polynomial equations whose unknowns are the model parameters. The process of solving these polynomial equations is known as the \textit{method of moments} for Gaussian mixtures.

For a concrete example, consider the case \( n = 1 \) and \( d = 6 \). The Gaussian moment variety \( G_{1,6} \) is a surface of degree 15 in \( \mathbb{P}^6 \) that is cut out by 20 cubics. These cubics will be explained in Section 2. For \( k = 2 \) we obtain the variety of secant lines, here denoted \( \sigma_2(G_{1,6}) \).

This represents mixtures of two univariate Gaussians. It has the parametric representation

\[
\begin{align*}
m_0 &= 1 \\
m_1 &= \lambda \mu + (1 - \lambda) \nu \\
m_2 &= \lambda(\mu^2 + \sigma^2) + (1 - \lambda)(\nu^2 + \tau^2) \\
m_3 &= \lambda(\mu^3 + 3\mu \sigma^2) + (1 - \lambda)(\nu^3 + 3\nu \tau^2) \\
m_4 &= \lambda(\mu^4 + 6\mu^2 \sigma^2 + 3\sigma^4) + (1 - \lambda)(\nu^4 + 6\nu^2 \tau^2 + 3\tau^4) \\
m_5 &= \lambda(\mu^5 + 10\mu^3 \sigma^2 + 15\mu \sigma^4) + (1 - \lambda)(\nu^5 + 10\nu^3 \tau^2 + 15\nu \tau^4) \\
m_6 &= \lambda(\mu^6 + 15\mu^4 \sigma^2 + 45\mu^2 \sigma^4 + 15\sigma^6) + (1 - \lambda)(\nu^6 + 15\nu^4 \tau^2 + 45\nu^2 \tau^4 + 15\tau^6)
\end{align*}
\]

These are obtained from the first seven coefficients in the moment generating function

\[
\sum_{i=0}^{\infty} \frac{m_i t^i}{i!} = \lambda \cdot \exp(\mu t + \frac{1}{2} \sigma^2 t^2) + (1 - \lambda) \cdot \exp(\nu t + \frac{1}{2} \tau^2 t^2).
\]

Here and throughout we use the standard notation \( \sigma^2 \) for the variance \( \sigma_{11} \) when \( n = 1 \). The variety \( \sigma_2(G_{1,6}) \) is five-dimensional, so it is a hypersurface in \( \mathbb{P}^6 \). In Section 3 we derive:

**Theorem 1.** The defining polynomial of \( \sigma_2(G_{1,6}) \) is a sum of 31154 monomials of degree 39. This polynomial has degrees 25, 33, 32, 23, 17, 12, 9 in \( m_0, m_1, m_2, m_3, m_4, m_5, m_6 \) respectively.

We see in particular that \( m_6 \) can be recovered from \( m_1, m_2, m_3, m_4 \) and \( m_5 \) by solving a univariate equation of degree 9. This number is of special historic interest. The 1894 paper [10] introduced the method of moments and, in our view, it is the first paper in algebraic statistics. Pearson analyzed phenotypic data from two crab populations, and he showed how to find the five parameters in [3] by solving an equation of degree 9 if the first five moments are given. The two occurrences of the number 9 are equivalent, in light of Lazard’s result [9] that the parameters \( \lambda, \mu, \nu, \sigma, \tau \) are rational functions in the first six moments \( m_1, \ldots, m_6 \).

The hypersurface in \( \mathbb{P}^6 \) described in Theorem 1 contains a familiar threefold, namely the determinantal variety \( \sigma_2(\nu_6(\mathbb{P}^1)) \) defined by the \( 3 \times 3 \)-minors of the \( 4 \times 4 \)-Hankel matrix

\[
\begin{pmatrix}
m_0 & m_1 & m_2 & m_3 \\
m_1 & m_2 & m_3 & m_4 \\
m_2 & m_3 & m_4 & m_5 \\
m_3 & m_4 & m_5 & m_6
\end{pmatrix}.
\]

This can be seen by setting \( \sigma = \nu = 0 \) in the parametrization [3]. Indeed, if the variances tend to zero then the Gaussian mixture converges to a mixture of the point distributions, supported at the means \( \mu \) and \( \nu \). The first \( d + 1 \) moments of point distributions form the
rational normal curve in $\mathbb{P}^d$, consisting of Hankel matrices of rank 1. Their $k$th mixtures specify a secant variety of the rational normal curve, consisting of Hankel matrices of rank $k$.

The last four sections of this paper are organized as follows. In Sections 3 and 4 we focus on mixtures of univariate Gaussians. We derive Pearson’s hypersurface $\sigma_2(G_{1,6})$ in detail, and we examine the varieties $\sigma_2(G_{1,d})$ for $d > 6$ and $\sigma_k(G_{1,3k})$ for $k = 3, 4$. In Section 5 we apply the method of moments to the data discussed in [1, §3], thus offering a comparison to maximum likelihood estimation. In Section 6 we explore some cases of the moment varieties for Gaussian mixtures with $n = 2$, and we discuss directions for future research.

2 Gaussian Moment Varieties

In this section we examine the Gaussian moment varieties $G_{n,d}$, starting with the case $n = 1$. The moment variety $G_{1,d}$ is a surface in $\mathbb{P}^d$. Its defining polynomial equations are as follows:

**Proposition 2.** Let $d \geq 3$. The homogeneous prime ideal of the Gaussian moment surface $G_{1,d}$ is minimally generated by $\binom{d}{3}$ cubics. These are the $3 \times 3$-minors of the $3 \times d$-matrix

$$H_d = \begin{pmatrix} 0 & m_0 & 2m_1 & 3m_2 & 4m_3 & \cdots & (d-1)m_{d-2} \\ m_0 & m_1 & m_2 & m_3 & m_4 & \cdots & m_{d-1} \\ m_1 & m_2 & m_3 & m_4 & m_5 & \cdots & m_d \end{pmatrix}.$$

**Proof.** Let $I_d = \mathcal{I}(G_{1,d})$ be the vanishing ideal of the moment surface, and let $J_d$ be the ideal generated by the $3 \times 3$-minors of $H_d$. A key observation, easily checked in [3], is that the moments of the univariate Gaussian distribution satisfy the recurrence relation

$$m_i = \mu m_{i-1} + (i-1)\sigma^2 m_{i-2} \quad \text{for} \quad i \geq 1. \quad (5)$$

Hence the row vector $(\sigma^2, \mu, -1)$ is in the left kernel of $H_d$. Thus $\text{rank}(H_d) = 2$, and this means that all $3 \times 3$-minors of $H_d$ indeed vanish on the surface $G_{1,d}$. This proves $J_d \subseteq I_d$.

From the previous inclusion we have $\text{dim}(V(J_d)) \geq 2$. Fix a monomial order such that the antidiagonal product is the leading term in each of the $3 \times 3$-minors of $H_d$. These leading terms are the distinct cubic monomials in $m_1, m_2, \ldots, m_{d-2}$. Hence the initial ideal satisfies

$$\langle m_1, m_2, \ldots, m_{d-2} \rangle^3 \subseteq \text{in}(J_d). \quad (6)$$

This shows that $\text{dim}(V(J_d)) = \text{dim}(V(\text{in}(J_d))) \leq 2$, and hence $V(J_d)$ has dimension 2 in $\mathbb{P}^d$.

We next argue that $V(J_d)$ is an irreducible surface. On the affine space $\mathbb{A}^d = \{m_0 = 1\}$, this clearly holds, even ideal-theoretically, because the minor indexed by 1, 2 and $i$ expresses $m_i$ as a polynomial in $m_1$ and $m_2$. Consider the intersection of $V(J_d)$ with $\mathbb{P}^{d-1} = \{m_0 = 0\}$. The matrix $H_d$ shows that $m_1 = m_2 = \cdots = m_{d-2} = 0$ holds on that hyperplane at infinity, so $V(J_d) \cap \{m_0 = 0\}$ is a curve. Every point on that curve is the limit of points in $V(J_d) \cap \{m_0 = 1\} = V(J_d) \cap \{m_0 = 1\}$, obtained by making $(\mu, \sigma)$ larger in an appropriate direction. This shows that $V(J_d)$ is irreducible, and we conclude that $V(J_d) = V(I_d)$.

At this point we only need to exclude the possibility that $J_d$ has lower-dimensional embedded components. However, there are no such components because the ideal of maximal
minors of a $3 \times d$-matrix of unknowns is Cohen-Macaulay, and $V(J_d)$ has the expected dimension for an intersection with $\mathbb{P}^d$. This shows that $J_d$ is a Cohen-Macaulay ideal. Hence $J_d$ has no embedded associated primes, and we conclude that $J_d = I_d$ as desired. \qed

**Corollary 3.** The $3 \times 3$-minors of the matrix $H_d$ form a Gröbner basis for the prime ideal of the Gaussian moment surface $G_{1,d} \subset \mathbb{P}^d$ with respect to the reverse lexicographic term order.

**Proof.** The ideal $J_d$ of $G_{1,d}$ is generated by the $3 \times 3$-minors of $H_d$. Our claim states that equality holds in (6). This can be seen by examining the Hilbert series of both ideals. It is well known that the ideal of $r \times r$-minors of a generic $r \times d$-matrix has the same numerator of the Hilbert series as the $r$-th power of the maximal ideal $\langle m_1, m_2, \ldots, m_{d-r+1} \rangle$. Since that ideal is Cohen-Macaulay, this Hilbert series numerator remains unchanged under transverse linear sections. Hence our ideal $J_d$ has the same Hilbert series numerator as $\langle m_1, m_2, \ldots, m_{d-2} \rangle^3$. This implies that the two ideals in (6) have the same Hilbert series, so they are equal. \qed

The argument above tells us that our surface has the same degree as $\langle m_1, m_2, \ldots, m_{d-2} \rangle^3$:

**Corollary 4.** The Gaussian moment surface $G_{1,d}$ has degree $\left(\begin{array}{c} d \\ 3 \end{array}\right)$ in $\mathbb{P}^d$.

It is natural to ask whether the nice determinantal representation extends to the varieties $G_{n,d}$ when $n \geq 2$. The answer is no, even in the first nontrivial case, when $n = 2$ and $d = 3$:

**Proposition 5.** The 5-dimensional variety $G_{2,3}$ has degree 16 in $\mathbb{P}^9$. Its homogeneous prime ideal is minimally generated by 14 cubics and 4 quartics, and the Hilbert series equals

$$\frac{1 + 4t + 10t^2 + 6t^3 - 4t^4 - t^5}{(1 - t)^6}.$$  

Starting from four of the cubics, the ideal can be computed by a saturation as follows:

$$\langle 2m_{10}^3 - 3m_{00}m_{10}m_{20} + m_{00}^2m_{30}, 2m_{01}m_{20}^2 - 2m_{00}m_{10}m_{11} - m_{00}m_{01}m_{20} + m_{00}^2m_{21}, 2m_{01}^2m_{10} - m_{00}m_{02}m_{10} - 2m_{00}m_{01}m_{11} + m_{00}^2m_{12}, 2m_{01}^3 - 3m_{00}m_{01}m_{02} + m_{00}^2m_{03} \rangle : \langle m_{00} \rangle^\infty. \quad (7)$$

The four special cubics in (7) above are the cumulants $k_{30}, k_{21}, k_{12}, k_{03}$ when expressed in terms of moments. The same technique works for all $n$ and $d$, and we shall now explain it.

We next define cumulants. These form a coordinate system that is more efficient than the moments, not just for Gaussians but for any probability distribution on $\mathbb{R}^n$ that is polynomial in the sense of Belkin and Sinha [3]. We introduce two exponential generating functions

$$M = \sum_{i_1, i_2, \ldots, i_n \geq 0} \frac{m_{i_1i_2\ldots i_n}}{i_1!i_2! \cdots i_n!} t_1^{i_1} t_2^{i_2} \cdots t_n^{i_n} \quad \text{and} \quad K = \sum_{i_1, i_2, \ldots, i_n \geq 0} \frac{k_{i_1i_2\ldots i_n}}{i_1!i_2! \cdots i_n!} t_1^{i_1} t_2^{i_2} \cdots t_n^{i_n}.$$  

Fixing $m_{00\ldots 0} = 1$ and $k_{00\ldots 0} = 0$, these are related by the identities of generating functions

$$M = \exp(K) \quad \text{and} \quad K = \log(M). \quad (8)$$

The coefficients are unknowns: the $m_{i_1i_2\ldots i_n}$ are moments, and the $k_{i_1i_2\ldots i_n}$ are cumulants. The integer $i_1 + i_2 + \cdots + i_n$ is the order of the moment $m_{i_1i_2\ldots i_n}$ or the cumulant $k_{i_1i_2\ldots i_n}$.
The identity (8) expresses moments of order \( \leq d \) as polynomials in cumulants of order \( \leq d \), and vice versa. Either of these can serve as an affine coordinate system on the \( \mathbb{P}^N \) whose points are inhomogeneous polynomials of degree \( \leq d \) in \( n \) variables. To be precise, the affine space \( \mathbb{A}^N = \{m_{00 \ldots 0} = 1\} \) consists of those polynomials whose constant term is nonzero. Hence the formulas (8) represent a non-linear change of variables on \( \mathbb{A}^N \). This was called Cremona linearization in \( [5] \). We agree with the authors of \( [5] \) that passing from \( m \)-coordinates to \( k \)-coordinates usually simplifies the description of interesting varieties in \( \mathbb{P}^N \).

We define the affine Gaussian moment variety to be the intersection of \( G_{n,d} \) with the affine chart \( \mathbb{A}^N = \{m_{00 \ldots 0} = 1\} \) in \( \mathbb{P}^N \). The transformation (8) between moments and cumulants is an isomorphism. Under this isomorphism, the affine Gaussian moment variety is the linear space defined by the vanishing of all cumulants of orders 3 and 4. Hence the formulas (8) represent a non-linear change of variables on \( \mathbb{A}^N \).

Remark 6. The affine moment variety \( G_{n,d} \cap \mathbb{A}^N \) is an affine space of dimension \( n + \binom{n+1}{2} \).

For instance, the 5-dimensional affine variety \( G_{2,3} \cap \mathbb{A}^9 \) is isomorphic to the 5-dimensional linear space defined by \( k_{30} = k_{21} = k_{12} = k_{03} = 0 \). This was translated into moments in (7).

For the purpose of studying mixtures, the first truly interesting bivariate case is \( k_{30} = k_{21} = k_{12} = k_{03} = 0 \). Here the affine moment variety \( G_{2,4} \cap \mathbb{A}^{14} \) is defined by the vanishing of the nine cumulants

\[
\begin{align*}
k_{03} &= 2m_{10}^3 - 3m_{02}m_{00} + m_{03} \\
k_{12} &= 2m_{01}m_{10} - 2m_{01}m_{11} - m_{02}m_{10} + m_{12} \\
k_{21} &= 2m_{01}m_{20} - m_{01}m_{21} - 2m_{10}m_{11} + m_{21} \\
k_{30} &= 2m_{10}^3 - 3m_{10}m_{20} + m_{30} \\
k_{04} &= -6m_{01}^4 + 12m_{01}m_{02} - 4m_{01}m_{03} - 3m_{02}^2 + m_{04} \\
k_{13} &= -6m_{01}m_{10} + 6m_{02}m_{11} + 6m_{01}m_{02}m_{10} - 3m_{01}m_{12} - 3m_{02}m_{11}m_{03}m_{10} + m_{13} \\
k_{22} &= -6m_{01}^2m_{10} + 2m_{01}m_{20} + 8m_{01}m_{10}m_{11} + 2m_{02}m_{10}^2 - 2m_{01}m_{21} - m_{02}m_{20} - 2m_{10}m_{12} - 2m_{11}^2 + m_{22} \\
k_{31} &= -6m_{01}m_{30}^3 + 6m_{01}m_{10}m_{20} + 6m_{10}^2m_{11} - m_{01}m_{30} - 3m_{10}m_{21} - 3m_{11}m_{20} + m_{31} \\
k_{40} &= -6m_{01}^4 + 12m_{01}m_{02}m_{20} - 4m_{10}m_{30} - 3m_{20}^2 + m_{40}
\end{align*}
\]

The ideal of the projective variety \( G_{2,4} \) is obtained from these nine polynomials by homogenizing and saturating with a new unknown \( m_{00} \). The result of this computation is as follows.

Proposition 7. The 5-dimensional variety \( G_{2,4} \) has degree 102 in \( \mathbb{P}^{14} \). Its prime ideal is minimally generated by 99 cubics, 41 quartics, and one quintic. The Hilbert series equals

\[
\frac{1 + 9t + 45t^2 + 66t^3 - 27t^4 + 13t^5 - 8t^6 + 4t^7 - t^8}{(1 - t)^6}.
\]

We note that the moment variety \( G_{2,4} \) contains the quartic Veronese surface \( \nu_4(\mathbb{P}^2) \). This surface is defined by 75 binomial quadrics in \( \mathbb{P}^{14} \), namely the 2 \( \times \) 2-minors of the matrix

\[
\begin{pmatrix}
m_{00} & m_{01} & m_{02} & m_{10} & m_{11} & m_{20} \\
m_{01} & m_{02} & m_{03} & m_{11} & m_{12} & m_{21} \\
m_{02} & m_{03} & m_{04} & m_{12} & m_{13} & m_{22} \\
m_{10} & m_{11} & m_{12} & m_{20} & m_{21} & m_{30} \\
m_{11} & m_{12} & m_{13} & m_{21} & m_{22} & m_{31} \\
m_{20} & m_{21} & m_{22} & m_{30} & m_{31} & m_{40}
\end{pmatrix}.
\]
As observed in [5, Section 4.3], this is just a linear coordinate space in cumulant coordinates:
\[ \nu_4(\mathbb{P}^2) \cap A^{14} = V(k_{20}, k_{11}, k_{02}, k_{30}, k_{21}, k_{12}, k_{03}, k_{40}, k_{31}, k_{22}, k_{13}, k_{04}) = (k_{20}, k_{11}, k_{02}) \cap G_{2,4}. \]

The secant variety \( \sigma_2(\nu_4(\mathbb{P}^2)) \) comprises all ternary quartics of tensor rank \( \leq 2 \). It has dimension 5 and degree 75 in \( \mathbb{P}^{14} \), and its homogeneous prime ideal is minimally generated by 148 cubics, namely the \( 3 \times 3 \)-minors of the \( 6 \times 6 \) Hankel matrix in [9]. Also this ideal becomes much simpler when passing from moments to cumulant coordinates. Here, the ideal of \( \sigma_2(\nu_4(\mathbb{P}^2)) \cap A^{14} \) is generated by 36 binomial quadrics, like \( k_{31}^2 - k_{22}k_{40} \) and \( k_{30}k_{31} - k_{21}k_{40} \), along with seven trinomial cubics like \( 2k_{20}^2 - k_{30}^2 + k_{20}k_{40} \) and \( 2k_{11}k_{20}^2 - k_{21}k_{30} + k_{11}k_{40} \).

**Remark 8.** The Gaussian moment variety \( G_{2,5} \) has dimension 5 in \( \mathbb{P}^{19} \), and we found its degree to be 332. However, at present, we do not know a generating set for its prime ideal.

We close this section by reporting the computation of the first interesting case for \( n = 3 \).

**Proposition 9.** The Gaussian moment variety \( G_{3,3} \) has dimension 9 and degree 130 in \( \mathbb{P}^{19} \). Its prime ideal is minimally generated by 84 cubics, 192 quartics, 21 quintics, 15 sextics, 36 septics, and 35 octics. The Hilbert series equals
\[
1+10t+55t^2+136t^3-26t^4-150t^5+139t^6-127t^7+310t^8-449t^9+360t^{10}-160t^{11}+32t^{12}-t^{13}
\]
\[
\frac{1+10t+55t^2+136t^3-26t^4-150t^5+139t^6-127t^7+310t^8-449t^9+360t^{10}-160t^{11}+32t^{12}-t^{13}}{(1-t)^{10}}.
\]

## 3 Pearson’s Crabs: Algebraic Statistics in 1894

The method of moments in statistics was introduced by Pearson in his 1894 paper [10]. In our view, this can be regarded as the beginning of Algebraic Statistics. In this section we revisit Pearson’s computation and related work of Lazard [9], and we extend them further.

The first six moments were expressed in (3) in terms of the parameters. The equation \( K = \log(M) \) in (8) writes the first six cumulants in terms of the first six moments:

\[
\begin{align*}
k_1 &= m_1, \\
k_2 &= m_2 - m_1^2, \\
k_3 &= m_3 - 3m_1m_2 + 2m_1^3, \\
k_4 &= m_4 - 4m_1m_3 - 3m_2^2 + 12m_1^2m_2 - 6m_1^4, \\
k_5 &= m_5 - 5m_1m_4 - 10m_2m_3 + 20m_2^2m_2 + 30m_1m_3^2 - 60m_1^3m_2 + 24m_1^5, \\
k_6 &= m_6 - 6m_1m_5 - 15m_2m_4 + 30m_2^2m_3 + 10m_3^2m_2 - 120m_1m_2m_3 + 120m_1^3m_2 - 120m_1^3m_3 \\
&\quad + 30m_2^3 - 270m_1^2m_2^2 + 360m_1^4m_2 - 120m_1^6.
\end{align*}
\]

Pearson’s method of moments identifies the parameters in a mixture of two univariate Gaussians. Suppose the first five moments \( m_1, m_2, m_3, m_4, m_5 \) are given numerically from data. Then we obtain numerical values for \( k_1, k_2, k_3, k_4, k_5 \) from the formulas in (10). Pearson [10] solves the corresponding five equations in (3) for the five unknowns \( \lambda, \mu, \nu, \sigma, \tau \). The crucial first step is to find the roots of the following univariate polynomial of degree 9 in \( p \).
Proposition 10. The product of normalized means \( p = (\mu - m_1)(\nu - m_1) \) satisfies
\[
8p^9 + 28kp^7 + 12kp^6 + (24k_3k_5 + 30k_3^2)p^5 + (148k_3^2k_4 - 6k_3^2)p^4 \\
+ (96k_3^4 + 9k_4^3 - 36k_3k_4k_5)p^3 + (-21k_3^2k_4^2 - 24k_3^3k_5)p^2 - 32k_3^4k_4p - 8k_3^6 = 0.
\] (11)

Proof. We first prove the identity \([11]\) under the assumption that the empirical mean is zero:
\[
m_1 = \lambda \mu + (1 - \lambda)\nu = 0.
\] (12)

In order to work modulo the symmetry that switches the two Gaussian components, we replace the unknown means \( \mu \) and \( \nu \) by their first two elementary symmetric polynomials:
\[
p = \mu \nu \quad \text{and} \quad s = \mu + \nu.
\] (13)

In \([10]\), Pearson applies considerable effort and cleverness to eliminating the unknowns \( \mu, \nu, \sigma, \tau, \lambda \) from the constraints \([3], [10], [13]\). We here offer a derivation that can be checked easily in a computer algebra system. We start by solving \([12]\) for \( \lambda \). Substituting
\[
\lambda = -\frac{\nu}{\mu - \nu}.
\] (14)

into \( k_2 = \lambda(\mu^2 + \sigma^2) + (1 - \lambda)(\nu^2 + \tau^2) \), we obtain the relation \( k_2 = -R_1 - p \), where
\[
R_1 = \frac{\sigma^2 \nu - \tau^2 \mu}{\mu - \nu}.
\] (15)

This the first of a series of semi-invariants \( R_i \) that appear naturally when trying to write the cumulant expressions in terms of \( p \) and \( s \). In the next instance, by letting
\[
R_2 = \frac{\sigma^2 - \tau^2}{\mu - \nu}
\] (16)

we can write \( k_3 = -(3R_2 + s)p \). In a similar way, we obtain
\[
\begin{align*}
k_4 &= 3R_3 + p(p - s^2) - 3k_2^2 \\
k_5 &= 5R_4p - sp(s^2 - 2p) - 10k_3k_2 \\
k_6 &= 15R_5 - p(s^4 - 3s^2p + p^2) - 15k_2^3 - 15k_2k_4 - 10k_3^2
\end{align*}
\] (17)

where
\[
\begin{align*}
R_3 &= (\mu\sigma^4 - \nu\tau^4 + 2\mu\nu^2\tau^2 - 2\mu^2\nu\sigma^2)/(\mu - \nu) \\
R_4 &= (3\tau^4 - 3\sigma^4 + 2\nu^2\tau^2 - 2\mu^2\sigma^2)/(\mu - \nu) \\
R_5 &= (\mu^4\nu\sigma^2 - \mu^4\tau^2 + 3\mu^2\nu\sigma^4 - 3\mu^2\nu\tau^2 + 3\nu^2\sigma^4 - 3\nu^2\tau^2 + 3\mu^4\nu\sigma^4 - 3\mu^4\nu\tau^2)/(\mu - \nu).
\end{align*}
\] (18)

It turns out that \( R_3, R_4, R_5 \) are not independent of \( R_1, R_2 \). Namely, we find
\[
\begin{align*}
R_3 &= R_1^2 + 2pR_1 - 2spR_2 - pR_2^2 \\
R_4 &= 2sR_1 + 6R_1R_2 + 2(p - s^2)R_2 - 3sR_2^2 \\
R_5 &= -R_3^3 - 3pR_2^2 + (s^2p - p^2)R_1 + 6spR_1R_2 + 3pR_1R_2^2 \\
&\quad + (2sp^2 - s^2p)R_2 + (3p^2 - 3s^2p)R_2^2 - spR_2^2.
\end{align*}
\] (19)
We now express the three right hand sides in terms of \( p, s, k_2, k_3 \) using the relations

\[
R_1 = -k_2 - p \quad \text{and} \quad R_2 = \frac{s}{3} - \frac{k_3}{3p}.
\]

Plugging the resulting expressions for \( R_3 \) and \( R_4 \) into the first two equations of (17), we get

\[
\begin{align*}
-2p^2 s^2 - 4spk_3 + 6p^3 + 3k_4p + k_3^2 & = 0, \\
-2p^2 s^3 + 4p^3 s + 5sk_3^2 - 20p^2 k_3 + 3k_5p & = 0.
\end{align*}
\]

(21)

Pearson’s polynomial (11) is the resultant of these two polynomials with respect to \( s \).

The proof is completed by noting that the entire derivation is invariant under replacing the parameters for the means \( \mu \) and \( \nu \) by the normalized means \( \nu - m_1 \) and \( \nu - m_2 \).

Remark 11. Gröbner bases reveal the following consequence of the two equations in (21):

\[
(4p^3 k_3 - 4k_3^3 - 6pk_3 k_4 - 2p^2 k_5)s + 4p^5 + 14p^2 k_4^2 + 8p^3 k_4 + k_3^2 k_4 + 3pk_4^2 - 2pk_3 k_5 = 0.
\]

(22)

This furnishes an expression for \( s \) as rational function in the quantities \( k_3, k_4, p \). Note that (11) and (22) do not depend on \( k_2 \) at all. The second moment \( m_2 \) is only involved via \( k_4 \).

We next derive the equation of the secant variety that was promised in the Introduction.

Proof of Theorem 4. Using (19) and (20), the last equation in (17) translates into

\[
\begin{align*}
-144p^5 + (72s^2 - 270k_2)p^4 + (90s^2 k_2 + 180sk_3 - 4s^4)p^3 + \\
(-135k_2 k_4 + 180sk_2 k_3 - 30s^3 k_3 - 90k_3^2 - 9k_6)p^2 - 30k_3^2(s^2 + \frac{3}{2} k_2)p + 5sk_3^3 & = 0.
\end{align*}
\]

(23)

We now eliminate the unknowns \( p \) and \( s \) from the three equations in (21) and (23). After removing an extraneous factor \( k_3^3 \), we obtain an irreducible polynomial in \( k_3, k_4, k_5, k_6 \) of degree 23 with 195 terms. This polynomial is also mentioned in [9, Proposition 12].

We finally substitute the expressions in (10) to get an inhomogeneous polynomial in \( m_1, m_2, \ldots, m_6 \) of degree 39 with 31154 terms. At this point, we check that this polynomial vanishes at the parametrization (3). To pass from affine space \( \mathbb{A}^6 \) to projective space \( \mathbb{P}^6 \), we introduce the homogenizing variable \( m_0 \), by replacing \( m_i \) with \( m_i/m_0 \) for \( i = 1, 2, 3, 4, 5, 6 \) and clearing denominators. The degree in each moment \( m_i \) is read off by inspection.

Remark 12. The elimination in the proof above can be carried out by computing a Gröbner basis for the ideal that is obtained by adding (23) to the system (21). Such a Gröbner basis reveals that both \( p \) and \( s \) can be expressed as rational functions in the cumulants. This confirms Lazard’s result [9] that Gaussian mixtures for \( k = 2 \) and \( n = 1 \) are rationally identifiable from their moments up to order six. We stress that Lazard [9] does much more than proving rational identifiability: he also provides a very detailed analysis of the real structure and special fibers of the map \( (\lambda, \mu, \nu, \sigma, \tau) \mapsto (m_1, m_2, m_3, m_4, m_5, m_6) \) in (3).
We close this section by stating the classical method of moments and by revisiting Pearson’s application to crab measurements. For $k = 2, n = 1$, the method works as follows. From the data, compute the empirical moments $m_1, \ldots, m_5$, and derive the cumulants $k_3, k_4, k_5$ via (10). Next compute the nine complex zeros of the Pearson polynomial (11). We are only interested in zeros $p$ that are real and non-positive, because $(\mu - m_1)(\nu - m_1) \leq 0$. All other zeros get discarded. For each non-positive zero $p$ of (11), compute the corresponding $s$ from (22). By (13), we obtain $\mu$ and $\nu$ as the two zeros of the equation $x^2 - sx + p = 0$. The mixture parameter $\lambda$ is given by (14). Finally, since $R_1$ and $R_2$ are now known by (20), we obtain $\sigma^2$ and $\tau^2$ by solving an inhomogeneous system of two linear equations, (15) and (16).

The algorithm in the previous paragraph works well when $m_1, m_2, m_3, m_4, m_5$ are general enough. For special values of the empirical moments, however, one might encounter zero denominators and other degeneracies. Extra care is needed in those cases. We implemented a complete method of moments (for $n = 1, k = 2$) in the statistics software R. Note that what we described above computes $\mu - m_1, \nu - m_1$, so we should add $m_1$ to recover $\mu$ and $\nu$.

Pearson [10] applied his method to measurements taken from crabs in the Bay of Naples, which form different populations. His data set is the histogram shown in blue in Figure 1.

![Gaussian mixture model for crabs data](image)

**Figure 1:** The crab data in the histogram is approximated by the mixture of two Gaussians. Pearson’s method gives the parameters $\mu = 0.633, \sigma = 0.018, \nu = 0.657, \tau = 0.012, \lambda = 0.414$. Pearson computes the empirical moments from the crab data, and he takes these as the numerical values for $m_1, m_2, m_3, m_4, m_5$. The resulting nonic polynomial (11) has three real roots, two of which are non-positive. One computes the model parameters as above. At
this point, Pearson has two statistically meaningful solutions. To choose between them, he computes \( m_6 \) in each case, and selects the model that is closest to the empirical \( m_6 \). The resulting probability density function and its mixture components are shown in Figure 1.

## 4 Mixtures of Univariate Gaussians

Our problem is to study the higher secant variety \( \sigma_k(\mathcal{G}_{1,d}) \) of the moment surface \( \mathcal{G}_{1,d} \subset \mathbb{P}^d \) whose equations were given in Proposition 2. The hypersurface \( \sigma_2(\mathcal{G}_{1,6}) \) was treated in Theorem 1. In the derivation of its equation in the previous section, we started out with introducing the new unknowns \( s = \mu + \nu \) and \( p = \mu \nu \). After introducing cumulant coordinates, the defining expressions for the moments \( m_4, m_5, m_6 \) in (3) turned into the three equations (21), (23) in \( k_2, k_3, k_4, k_5, k_6, s, p \), and from these we then eliminated \( s \) and \( p \).

The implicitization problem for \( \sigma_2(\mathcal{G}_{1,d}) \) when \( d > 6 \) can be approached with the same process. Starting from the moments, we derive polynomials in \( k_2, k_3, \ldots, k_d, s, p \) that contain \( k_d \) linearly. The extra polynomial that contains \( k_7 \) linearly and is used for \( \sigma_2(\mathcal{G}_{1,7}) \) equals

\[
16p^3s^5 - 126k_2p^3s^3 + 42k_3p^2s^4 - 148p^4s^3 + 252k_2p^4s - 126k_3p^3s^2
+ 216p^5s + 315k_2k_3p^2s - 1260k_2k_3p^3 - 35k_3^2s^2 + 210k_3^2p^2s - 378k_3p^4
+ 189k_2k_5p^2 + 35k_3k_4p^2 + 9k_7p^2.
\]

(24)

The extra polynomial that contains \( k_8 \) linearly and is used for \( \sigma_2(\mathcal{G}_{1,8}) \) equals

\[
20p^4s^6 + 336k_2p^4s^4 - 112k_3p^3s^5 + 124p^5s^4 - 3780k_2^2p^4s^2 + 2520k_2k_3p^3s^3 - 6048k_2p^5s^2
- 420k_3^2p^2s^4 + 2128k_3^2p^4s^3 - 2232p^6s^2 - 7560k_2^2k_3p^3s + 11340k_2k_3^2p^2s^2
- 15120k_2k_3p^4s + 12096k_2p^6 - 280k_3^2ps^3 + 2940k_3^2p^3s^2 - 7056k_3p^5s + 3564p^7
+ 1890k_2k_3^2p^2 + 5670k_2k_4p^3 - 420k_2k_3^2ps + 7560k_2k_3^2p^3 + 35k_3^2s^2 + 280k_3^2p^2s
- 1260k_2p^4 + 756k_2k_6p^3 - 35k_3p + 1512k_3k_5p^3 + 945k_4p^3 + 27k_8p^3.
\]

(25)

**Proposition 13.** The ideals of the 5-dimensional varieties \( \sigma_2(\mathcal{G}_{1,7}) \cap A^7 \) and \( \sigma_2(\mathcal{G}_{1,8}) \cap A^8 \) in cumulant coordinates are obtained from (21), (23), (24) and (25) by eliminating \( s \) and \( p \).

The polynomials above represent a sequence of birational maps \( \sigma_2(\mathcal{G}_{1,d}) \rightarrow \sigma_2(\mathcal{G}_{1,d-1}) \), which allow us to recover all cumulants from earlier cumulants and the parameters \( p \) and \( s \). In particular, by solving the equation (11) for \( p \) and then recovering \( s \) from (22), we can invert the parametrization for any of the moment varieties \( \sigma_2(\mathcal{G}_{1,d}) \subset \mathbb{P}^d \). If we are given \( m_1, m_2, m_3, m_4, m_5 \) from data then we expect \( 18 = 9 \times 2 \) complex solutions \( (\lambda, \mu, \nu, \sigma, \tau) \). The extra factor of 2 comes from label swapping between the two Gaussians. In that sense, the number 9 is the algebraic degree of the identifiability problem for \( n = 1 \) and \( k = 2 \).

We next move on to \( k = 3 \). There are now eight model parameters. These are mapped to \( \mathbb{P}^8 \) with coordinates \( (m_8 : m_1 : \cdots : m_8) \), and we are interested in the degree of that map.

Working in cumulant coordinates as in Section 3 and using the Gröbner basis package FGb in maple, we computed the degree of that map. It turned out to be \( 1350 = 3! \cdot 225 \).

**Theorem 14.** The mixture model of \( k = 3 \) univariate Gaussians is algebraically identifiable from its first eight moments. The algebraic degree of this identifiability problem equals 225.
We also computed a generalized Pearson polynomial of degree 225 for \( k = 3 \). Namely, we replace the three means \( \mu_1, \mu_2, \mu_3 \) by their elementary symmetric polynomials \( e_1 = \mu_1 + \mu_2 + \mu_3, e_2 = \mu_1 \mu_2 + \mu_1 \mu_3 + \mu_2 \mu_3 \) and \( e_3 = \mu_1 \mu_2 \mu_3 \). This is done by a derivation analogous to [10]-[21]. This allows us to eliminate all model parameters other than \( e_1, e_2, e_3 \). The details and further computational results will be presented in a forthcoming article.

We compute a lexicographic Gröbner basis \( G \) for the above equations in \( \mathbb{R}[e_1, e_2, e_3] \), with generic numerical values of the eight moments \( m_1, \ldots, m_8 \). It has the expected shape

\[
G = \{ f(e_1), e_2 - g(e_1), e_3 - h(e_1) \}.
\]

Here \( f, g, h \) are univariate polynomials of degrees 225, 224, 224 respectively. In particular, \( f \) is the promised generalized Pearson polynomial of degree 225 for mixtures of three Gaussians.

For general \( k \), the mixture model has \( 3k - 1 \) parameters. Based on what we know for \( k = 2 \) and \( k = 3 \), we offer the following conjecture concerning the identifiability of Gaussian mixtures. Recall that the double-factorial is the product of the smallest odd positive integers:

\[
(2k - 1)!! = 1 \cdot 3 \cdot 5 \cdots (2k - 1).
\]

**Conjecture 15.** The mixture model of \( k \) univariate Gaussians is algebraically identifiable by the moments of order \( \leq 3k - 1 \), and the degree of this identifiability problem equals \( \left( (2k - 1)!! \right)^2 \). Moreover, this model is rationally identifiable by the moments of order \( \leq 3k \).

Geometrically, this conjecture states that the moment variety \( \sigma_k(G_{1,3k-1}) \) fills the ambient space \( \mathbb{P}^{3k-1} \), and that \( \sigma_k(G_{1,3k}) \) is a hypersurface in \( \mathbb{P}^{3k} \) whose secant parametrization is birational. As explained in the Introduction, a priori we only know that the dimension of \( \sigma_k(G_{1,d}) \) is equal to \( 3k - 1 \) for \( d \gg 0 \). What Conjecture 15 implies is that this already holds for \( d = 3k - 1 \), so that the secant varieties always have the expected dimension. We know this result for \( k = 2 \) by the work of Pearson [10] and Lazard [9] that was discussed in Section 3. For \( k = 3 \) we verified the first part of the conjecture, but we do not yet know whether rational identifiability holds. Also, we do not know the degree of the hypersurface \( \sigma_3(G_{1,9}) \subset \mathbb{P}^9 \). The double-factorial conjecture for the degree is nothing but a wild guess.

Computations for \( k = 4 \) appear currently out of reach for Gröbner basis methods. If our wild guess is true then the expected number of complex solutions for the 11 moment equations whose solution identifies a mixture of \( k = 4 \) univariate Gaussians is \( 105^2 \times 4! = 264,600 \).

## 5 Method of Moments versus Maximum Likelihood

In [11 Section 3], the sample consisting of the following \( N = 2K \) data points was examined:

\[
1, 1.2, 2, 2.2, 3, 3.2, 4, \ldots, K, K + 0.2 \quad (\text{for } K > 1).
\]

(26)

Its main purpose was to show that, unlike most models studied in Algebraic Statistics, there is no notion of maximum likelihood degree (or ML degree; see [6]) for a mixture of two Gaussians. Indeed, the particular sample in (26) has the property that, as \( K \) increases,
the number of critical points of the log-likelihood function grows without any bound. More
precisely, for each ‘cluster’ or pair \((k, k + 0.2)\), one can find a non-trivial critical point
\((\hat{\lambda}, \hat{\mu}, \hat{\nu}, \hat{\sigma}, \hat{\tau})\) of the likelihood equations such that the mean estimate \(\hat{\mu}\) lies between them.

In this section we apply Pearson’s method of moments to this sample. The special nature
of the data raises some interesting considerations. As we shall see, the even spacing of the
points in the list (26) implies that all empirical cumulants of odd order \(\geq 3\) vanish:

\[
k_3 = k_5 = k_7 = k_9 = \cdots = 0. \tag{27}
\]

Let us analyze what happens when applying the method of moments to any sample that
satisfies (27). Under this hypothesis Pearson’s polynomial (11) factors as follows:

\[
8p^9 + 28p^7k_4 + 30p^5k_4^2 + 9p^3k_4^3 = 8p^3\left(p^2 + \frac{3}{2}k_4\right)^2 \left(p^2 + \frac{1}{2}k_4\right) = 0. \tag{28}
\]

Recall that \(p\) represents \(p = (\mu - m_1)(\nu - m_1)\). The first root of the Pearson polynomial is
\(p = 0\). This implies \(m_1 = \mu\) or \(m_1 = \nu\). Since \(m_1\) is the mean of \(\mu\) and \(\nu\), we conclude that
the means are equal: \(m_1 = \mu = \nu\). However, the equal-means model cannot be recovered
from the first five moments. To see this, note that the equations for cumulants \(k_1 = 0, k_3 = 0\)
and \(k_5 = 0\) become \(0 = 0\), yielding no information on the remaining three parameters.

If we assume that also the sixth moment \(m_6\) is known from the data, then the parameters
can be identified. The original system (3) under the equal-means model \(\mu = \nu = 0\) equals

\[
m_2 = \lambda\sigma^2 + (1 - \lambda)\tau^2
\]
\[
m_4 = 3\lambda\sigma^4 + 3(1 - \lambda)\tau^4
\]
\[
m_6 = 15\lambda\sigma^6 + 15(1 - \lambda)\tau^6. \tag{29}
\]

After some rewriting and elimination:

\[
\lambda(\sigma^2 - \tau^2) = k_2 - \tau^2
\]
\[
5k_4(\sigma^2 + \tau^2) = 10k_2k_4 + k_6
\]
\[
15k_4(\sigma^2\tau^2) = 3k_2k_6 + 15k_2^2k_4 - 5k_4^2. \tag{30}
\]

Assuming \(k_4 \neq 0\), this system can be solved easily in radicals for \(\lambda, \sigma, \tau\).

If \(k_4 \geq 0\) then \(p = 0\) is the only real zero of (28). If \(k_4 < 0\) then two other solutions are:

\[
p = -\sqrt{-\frac{3}{2}k_4} \quad \text{and} \quad p = -\sqrt{-\frac{1}{2}k_4}. \tag{31}
\]

Note that \(p\) must be negative because it is the product of the two normalized means.

The mean of the sample in (26) is \(m_1 = K/2 + 3/5\). The central moments are

\[
m_r = \frac{1}{2K} \left(\sum_{i=1}^{K} (i - m_1)^r + \sum_{i=1}^{K} (i - m_1 + \frac{1}{3})^r\right) \quad \text{for} \ r = 2, 3, 4, \ldots. \tag{32}
\]
This expression is a polynomial of degree \( r \) in \( K \). That polynomial is zero when \( r \) is odd. Using (10), this implies the vanishing of the odd sample cumulants (27). For even \( r \), we get

\[ m_2 = \frac{1}{12} K^2 - \frac{11}{150}, \quad m_4 = \frac{1}{80} K^4 - \frac{11}{300} K^2 + \frac{91}{375}, \quad m_6 = \frac{1}{480} K^6 - \frac{11}{800} K^4 + \frac{91}{300} K^2 - \frac{12347}{656250}. \]

These polynomials simplify to binomials when we substitute the moments into (10):

\[ k_1 = m_1 = \frac{K}{2} + 0.6, \quad k_2 = \frac{K^2}{12} - \frac{11}{150}, \quad k_4 = -\frac{K^4}{120} + \frac{61}{7500}, \quad k_6 = \frac{K^6}{252} - \frac{7781}{1968750}. \] (33)

These are the sample cumulants. We are aware that these are biased estimators, and \( k \)-statistics might be preferable. However, for simplicity, we shall use (33) in our derivation.

Since \( K \geq 1 \), we have \( k_4 < 0 \) in (33). Hence the Pearson polynomial has three distinct real roots. For \( p = 0 \), substituting (27) and (33) into (30) shows that, for every value of \( K \), there are no positive real solutions for both \( \sigma \) and \( \tau \). Thus the method of moments concludes that the sample does not come from a mixture of two Gaussians with the same mean.

Next we consider the two other roots in (31). To recover the corresponding \( s \)-values, we use the system (21) with all odd cumulants replaced by zero:

\[ p(6p^2 - 2s^2p + 3k_4) = 0 \]
\[ 2sp^2(2p - s^2) = 0 \] (34)

For \( p = -\sqrt{\frac{-3}{2} k_4} \), the first equation gives \( s \neq 0 \), and the second yields a non-real value for \( s \), so this is not viable. For \( p = -\sqrt{\frac{-1}{2} k_4} \), we obtain \( s = 0 \), and this is now a valid solution.

In conclusion, Pearson’s method of moments infers a non-equal-means model for the data (26). Using central moments, i.e. after subtracting \( m_1 = K/2 + 3/5 \) from each data point, we find \( \mu = -\nu = 4\sqrt{\frac{-k_4}{2}} \). These values lead to \( \lambda = \frac{1}{2} \) and \( \sigma = \tau \). The final estimate is

\[ (\lambda, \mu, \sigma^2, \nu, \tau^2) = \left( \frac{1}{2}, m_1 - \sqrt{\frac{-k_4}{2}}, k_2 - \sqrt{\frac{-k_4}{2}}, m_1 + \sqrt{\frac{-k_4}{2}}, k_2 - \sqrt{\frac{-k_4}{2}} \right). \] (35)

We are now in a position to compare this estimate to those found by maximum likelihood.

**Example 16.** (Example 2 of [1] with \( K = 7 \)) The sample consists of the 14 data points 1,1.2,2,2.2,3,3.2,4,4.2,5,5.2,6,6.2,7,7.2. The method of moments estimator (35) evaluates to

\[ (\lambda, \mu, \sigma, \nu, \tau) = \left( \frac{1}{2}, \sqrt[10]{\frac{41}{100001}}, \sqrt[10]{\frac{401}{100001}}, \frac{41}{100001}, \sqrt[10]{\frac{401}{100001}} \right). \]

For general \( k_3, k_4, k_5 \), Pearson’s equation (11) of degree 9 cannot be solved in radicals, as its roots are algebraic numbers with Galois group \( S_9 \) over \( \mathbb{Q} \). However, for our special data, the algebraic degree of the solution drops, and we could write the estimate in radicals.

The situation is dramatically different for likelihood inference. It was shown in [1] that the critical points for the likelihood function of the mixture of two Gaussians with data (26) have transcendental coordinates, and that the number of these critical points grows with \( K \).
It is thus interesting to assess the quality of our solution (35) from the likelihood perspective. The probability density function for the Gaussian mixture with these parameters is shown in Figure 2. The corresponding value of the log-likelihood function is $-28.79618895$.

If the estimate (35) is used as starting point in the EM algorithm, then it converges to the stationary point $(\lambda, \mu, \sigma, \nu, \tau) = (0.500000, 2.420362, 5.77968, 1.090329, 1.090329)$. That point has a log-likelihood value of approximately $-28.43415$. Comparing to Table 1 of [1], this value is only beaten by the critical points associated to the endpoints $k = 1$ and $k = 7$.

![Gaussian mixture model for sample with K=7](image)

Figure 2: The sample data for $K = 7$ (in blue) is approximated by a mixture of two Gaussians via the method of moments. The parameter values are derived in Example 16.

We make the following observation: of all the critical points listed in [1, Table 1], the middle clusters get the lowest log-likelihood. Hence an equal-means model is not very likely for this sample. This is further confirmed by the method of moments (MOM) since, as mentioned above, the equal-means model is inconsistent with our polynomial equations.

Behavior similar to Example 16 is observed for all $K \geq 2$. The MOM estimate separates the sample into two halves, and assigns the same variance to both Gaussian components. The exact parameter estimates are obtained by substituting $m_1, k_2, k_4$ from (33) into (35). For $K = 20$, the estimate computed by the EM algorithm with the MOM estimate as starting point beats in likelihood value all $K$ critical points listed in [1]. For $K > 20$, the likelihood value of the MOM estimate itself appears to be already better than the critical points listed in [1]. In other words, the MOM produces good starting points for maximum likelihood.
6 Higher Dimensions, Submodels and Next Steps

At present we know little about the moment varieties of Gaussian mixtures for \( n \geq 2 \), and we see this as an excellent topic for future investigations. A guiding question is the following:

**Problem 17.** Which order \( d \) of cumulants/moments is needed to make the mixture model \( \sigma_k(G_{n,d}) \) algebraically identifiable? Which order \( d \) is needed to obtain rational identifiability?

A natural conjecture is that the dimension of the variety \( \sigma_k(G_{n,d}) \) always coincides with the expected number (2), unless that number exceeds the dimension \( N \) of the ambient projective space. It is important to note that the analogous statement would not be true for the submodels where all covariance matrices are zero. These are the secant varieties of Veronese varieties, and there is a well-known list of exceptional cases, due to Alexander and Hirschowitz (cf. [4]), where these secant varieties do not have the expected dimension. However, none of these cases is relevant in the case of Gaussian mixtures discussed here.

The following is the first bivariate instance of the varieties \( \sigma_k(G_{n,d}) \) for Gaussian mixtures.

**Example 18.** Let \( k = 2, n = 2, d = 4 \). The variety \( \sigma_2(G_{2,4}) \) lives in the \( \mathbb{P}^{14} \) whose coordinates are the moments up to order 4. This is the variety of secant lines for the 5-dimensional variety featured in Proposition 7. We checked that \( \sigma_2(G_{2,4}) \) has the expected dimension, namely 11.

We found it difficult to compute polynomials that vanish on our moment varieties, including \( \sigma_2(G_{2,4}) \). One fruitful direction to make progress would be to first compute subvarieties that correspond to statistically meaningful submodels. Such submodels arise naturally when the parameters satisfy various natural constraints. We illustrate this for a small case.

Fix \( k = 2, n = 2, d = 3 \). The variety \( \sigma_2(G_{2,3}) \) is equal to its ambient space \( \mathbb{P}^9 \). We consider the two submodels: that given by equal variances and that given by equal means. The number of parameters are 8 and 9 respectively. Both of these models are not identifiable.

**Proposition 19.** The equal-means submodel of \( \sigma_2(G_{2,3}) \) has dimension 5 and degree 16. It is identical to the Gaussian moment variety \( G_{2,3} \) in Proposition 5 so the mixtures add nothing new in \( \mathbb{P}^9 \). The equal-variances submodel of \( \sigma_2(G_{2,3}) \) has dimension 7 and degree 15 in \( \mathbb{P}^9 \). Its ideal is Cohen-Macaulay and is generated by the maximal minors of the 6 \( \times \) 5-matrix

\[
\begin{pmatrix}
0 & 0 & m_{00} & m_{10} & m_{01} \\
0 & m_{10} & m_{20} & m_{30} & m_{21} \\
m_{01} & 0 & m_{02} & m_{12} & m_{03} \\
0 & m_{00} & 2m_{10} & 2m_{20} & 2m_{11} \\
m_{00} & 0 & 2m_{01} & 2m_{11} & 2m_{02} \\
m_{10} & m_{01} & 2m_{11} & 2m_{21} & 2m_{12}
\end{pmatrix}
\]  

(36)

This proposition is proved by a direct computation. That the equal-means submodel of \( \sigma_2(G_{2,3}) \) equals \( G_{2,3} \) is not so surprising, since the parametrization of the latter is linear in the variance parameters \( s_{11}, s_{12}, s_{22} \). This holds for all moments up to order 3. The same is no longer true for \( d \geq 4 \). On the other hand, it was gratifying to see an occurrence, in the matrix \( (36) \), of the Hilbert-Burch Theorem for Cohen-Macaulay ideals of codimension 2.
We already noted that secant varieties of Veronese varieties arise as the submodels where the variances are zero. On the other hand, we can also consider the submodels given by zero means. In that case we get the secant varieties of varieties of powers of quadratic forms. The following concrete example was worked out with some input from Giorgio Ottaviani.

**Example 20.** Consider the mixture of two bivariate Gaussians that are centered at the origin. This model has 7 parameters: there is one mixture parameter, and each Gaussian has a $2 \times 2$ covariance matrix, with three unknown entries. We consider the variety $\mathcal{V}$ that is parametrized by all moments of order exactly $d = 6$. This variety has only dimension 5. It lives in the $\mathbb{P}^6$ with coordinates $m_{06}, m_{15}, \ldots, m_{60}$. This hypersurface has degree 15. Its points are the binary octics that are sums of the third powers of two binary quadrics. Thus, this is the secant variety of a linear projection of the third Veronese surface from $\mathbb{P}^9$ to $\mathbb{P}^6$.

The polynomial that defines $\mathcal{V}$ has 1370 monomials of degree 15 in the six unknowns $m_{06}, m_{15}, \ldots, m_{60}$. In fact, this is the unique (up to scaling) invariant of binary sextics of degree 15. It is denoted $I_{15}$ in Faa di Bruno’s book [7, Table IV10], where a determinantal formula was given. A quick way to compute $\mathcal{V}$ by elimination is as follows. Start with the variety $\sigma_3(\nu_3(\mathbb{P}^2))$ of symmetric $3 \times 3 \times 3$-tensors of rank $\leq 2$. This is defined by the maximal minors of a Hankel matrix of size $3 \times 6$. It has degree 15 and dimension 5 in $\mathbb{P}^9$. Now project into $\mathbb{P}^6$. This projection has no base points, so the image is a hypersurface of degree 15.

In Example 20 we fixed the order of the moments. For certain applications, also taking moments of two orders makes sense. For instance, the tensor power method in machine learning [2, 8] uses the moments of order $d = 4$ and $d = 6$. We examine the corresponding variety for $n = k = 2$. This lives in the $\mathbb{P}^{12}$ with coordinates $m_{00}, m_{40}, m_{31}, m_{22}, m_{13}, m_{04}, m_{60}, m_{51}, m_{42}, m_{33}, m_{24}, m_{15}, m_{06}$. We start with the variety $X$ that is parametrized by the 4th and 6th powers of binary quadrics. This variety has dimension three and degree 27 in $\mathbb{P}^{12}$. We are interested in the secant variety $\sigma_2(X)$. This secant variety has the expected dimension 7, so the model is algebraically identifiable.

In summary, the study of moments of mixtures of Gaussians leads to many interesting projective varieties. Their geometry is still largely unexplored, and offers a fertile ground for investigations by algebraic geometers. On the statistical side, it is most interesting to understand the fibers of the natural parameterization of the variety $\sigma_k(\mathcal{G}_{n,d})$. Problem 17 serves as the guiding question. In the case of algebraic identifiability, we are always interested
in finding the algebraic degree of the parametrization, and in effective methods for solving for the model parameters. This will be the topic of a forthcoming paper by the same authors.
