HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Birefringence of light induced not by matter, but by the gradient of an electric field, has been predicted in 1955 and observed in 2008. Here we replace the electric field by the gravitational field of our expanding universe.

1 The Fedorov-Imbert effect

Considering the boundary between air (or vacuum) and a glass plate as a discontinuous electric field, Fedorov\(^1\) and Imbert\(^2\) predicted that photons of a given polarisation follow a discontinuous trajectory with an offset of the order of a wavelength as shown in Figure 1. Note that the infinite gradient of the electric field induces an infinite speed of light along the dotted line. The offset of photons of the opposite polarisation is in the opposite direction. Therefore photons of different polarisations follow different trajectories, an effect called birefringence or also Spin Hall Effect of Light.

![Figure 1](image_url)

This effect was observed for the first time 10 years ago\(^3,4\) using techniques of weak quantum measurement.

2 Adding spin to geodesics

Gravitational fields with gradient also induce birefringence of light. To see this we must generalize the geodesics, which describe trajectories of point-like test particles without spin in a gravitational field. The gravitational field is encoded in the Christoffel symbols of a pseudo-Riemannian metric.
Let $X^\mu(\tau)$ be the trajectory of a massless spinless particle with 4-velocity $dX^\mu/d\tau$ and 4-momentum $P^\mu(\tau)$. Its equations of motion (geodesics) read in first order formalism,

$$\frac{d}{d\tau} X^\mu = P^\mu, \quad (1)$$

$$\frac{D}{d\tau} P^\mu = 0, \quad (2)$$

with $D/d\tau$ denoting the covariant derivative with respect to the Christoffel symbols. The equations of motion have one conserved quantity, $P^\mu P_\mu = m^2 = 0$. Note that the massless limit is delicate; by the equivalence principle the geodesics for massive particles do not depend on this positive mass $m$ and the limit $m \to 0$ cannot be continuous.

In the seventies spin was added to the massless particle in the form of the antisymmetric spin tensor $S^\mu\nu(\tau)$ coupled to the gradient of the gravitational field encoded in the Riemann tensor.

$$\frac{d}{d\tau} X^\mu = P^\mu + 2 \frac{S^\mu_\nu R^\nu_\beta \rho \sigma S^\rho_\sigma P^\beta}{R^\alpha_\beta \rho \sigma S^\alpha_\beta S^\rho_\sigma}, \quad (3)$$

$$\frac{D}{d\tau} P^\mu = -s \sqrt{-\det(R^\alpha_\beta \rho \sigma S^\alpha_\beta S^\rho_\sigma)} P^\mu, \quad (4)$$

$$\frac{D}{d\tau} S^\mu\nu = P^\mu \frac{d}{d\tau} X^\nu - P^\nu \frac{d}{d\tau} X^\mu, \quad (5)$$

where $s$ is the “scalar spin” defined by

$$-\frac{1}{2} S^\mu_\nu S^\nu_\mu =: s^2. \quad (6)$$

Let us anticipate that upon a 3+1 split $X = (\vec{x}, t)$, the scalar spin becomes the projection of the spin 3-vector $\vec{s}$ onto the 3-moment $\vec{p}$ (or the highest and lowest weight of the spin representation). Photons have $s = \pm \hbar$.

In presence of spin, we have three more conserved quantities, the scalar spin $s$ and

$${P^\mu} \frac{d}{d\tau} X^\mu = 0, \quad S^\mu_\nu P^\nu = 0. \quad (7)$$

The equations of motion (3 - 5) for the massless particle with spin have three delicate properties:

- They are ill defined in Minkowski space because of the vanishing Riemann tensor.
- The limit of vanishing spin is delicate as for the limit of vanishing mass in the case of geodesics.
- We are confronted with super-luminal propagation velocities as in the Fedorov-Imbert effect.

Note also that all four conserved quantities are valid for an arbitrary metric, they do not derive from isometries via Emmy Noether’s theorem. A self-contained derivation of the equations of motion from the massive Mathisson-Papapetrou-Dixon equations can be found in the appendix of reference 9.

3 The example of the Robertson-Walker metric

In 1976 Saturnini has analyzed the equations of motion (3 - 5) for the Schwarzschild metric. Here we consider flat Robertson-Walker metrics.
Because of the many vector products in the computations we use Euclidean coordinates $\vec{x}$ and cosmic time $t$ and write the line element as $-a(t)^2 \, dx^2 + dt^2$, with positive scale factor $a > 0$, that we also suppose increasing, $a' > 0$. Thanks to Emmy Noether's theorem for the six Killing vectors for translations $\partial/\partial \vec{x}$ and rotations $\vec{x} \wedge \partial/\partial \vec{x}$ and the conformal Killing vector $a(t) \partial/\partial t$, the equations of motion reduce drastically and can be solved by a Runge-Kutta algorithm. Figure 2 shows a typical result in the $\Lambda$CDM model. For a given polarisation, $s = \bar{h}$, the trajectory of the photon is the helix. The dashed line is the trajectory of a 'photon' without spin, $(x^1(t), 0, 0)$. The transverse spin $\vec{s}_\perp$ at emission time $t_\epsilon$ is indicated by the short arrow at the left. The opposite polarisation, $s = -\bar{h}$, produces the same helix but of opposite chirality. The spin $\vec{s}$ precesses around the center of the helix with the same variable instantaneous period as the period of the helix. Let us denote this period by $T_{\text{helix}}(t)$. We also want to compute the position of the center $\vec{x}_{\text{center}}(t)$ of the helix and its radius $R_{\text{helix}}(t)$. To this end we linearize the equations of motion in the parameter $|\vec{s}_e| \lambda_e/(2\pi \bar{h} a_e)$, $\lambda_e$ being the wavelength at emission. For a Lyman $\alpha$ photon of redshift 2.4 this parameter is of the order of $10^{-34}$, well justifying the linear approximation. It yields:

$$T_{\text{helix}}(t) \sim \frac{a(t)}{a_e} \frac{\lambda_e}{1 + q(t)} \quad \text{with} \quad q := -a a''(t)/a'(t)^2. \quad (8)$$

$$\vec{x}_{\text{center}}(t) \sim \begin{pmatrix} x^1(t) \\ 0 \\ -\frac{\lambda_e}{2\pi a_e} (1 - a_e' x^1(t)) \end{pmatrix}, \quad R_{\text{helix}}(t) \sim \frac{a(t)}{a_e} \frac{\lambda_e}{2\pi}. \quad (9)$$

Note that in this approximation the projection of the helix on the null geodesic coincides with this geodesic at all times. To be concrete, consider a $z = 2.4$ Lyman $\alpha$ photon engaged in a race with a fictitious mass- and spinless competitor travelling at the speed of light. Both competitors are emitted by the same source at the same time, the race lasts $3 \cdot 10^9$ light years and they arrive simultaneously in our telescope. However, they arrive with a transverse offset of the order of $10^{-7}$ meter. To achieve this remarkable draw, the photon on its helix has to travel at roughly $\sqrt{2}$ times the speed of light during the entire race.

Said differently, the superluminal propagation in the equations of motion (3 - 5) does violate causality, but only at the tiny scale of the order of a wave length. For a quantum of solace, note that the support of the Feynman propagator of the Dirac operator in Minkowski space leaks
out of the light-cone\textsuperscript{10}. However this leakage is damped exponentially and also there, causality violation is extremely tiny.

Robertson-Walker metrics with curvature give similar results as computed in reference\textsuperscript{11}. There you also find an unsuccessful attempt on finding spin effects in the Hubble diagram of supernovae.

4 Conclusions and questions

- The gravitational field of an expanding universe produces birefringence of light.
- This birefringence carries information on the acceleration of the universe.
- Of course the main question is: Can this birefringence be measured?

In 1976 Saturnini\textsuperscript{8} has shown that the gravitational field of a static, spherical mass produces birefringence of light.

- How does birefringence in the Schwarzschild solution interfere with lensing?

Einstein predicted gravitational waves in 1916. They were observed in 2015. Concerning birefringence, three questions are immediate:

- Does the gravitational field of a gravitational wave also produce birefringence of light?
- If yes, what information is carried by this birefringence?
- Can this birefringence be measured in interferometers with polarized laser beams?

Taking due account of its spin, the photon propagates through an expanding universe on a helix. Did Feynman already know about this when he chose to represent the photon propagator by a curly line?

Acknowledgments

As always, it is a pleasure to thank Vera de Sá-Varanda, Jacques Dumarchez and their team for their warm and efficient hospitality.
