Kyoto University
ELECTRICAL CONDUCTIVITY OF CaSO₄ IN AQUEOUS SOLUTION UNDER HIGH PRESSURE

By Etsuko Inada, Kiyoshi Shimizu* and Jiro Osugi

The electrical conductivity of aqueous solutions of 2–2 electrolytes, CaSO₄ and MgSO₄, has been measured within the ranges, 15–40°C, 1–1,200 kg/cm² and 10⁻³–10⁻² M. The plots of 1 nC²/r² under high pressure show Kohlraush’s linear relation in this concentration range. The equivalent conductance at infinite dilution γ has a maximum against pressure. The pressure at this maximum point has been found to be higher than that of the minimum viscosity of water at each temperature. The hydration numbers of Ca²⁺, Mg²⁺ and SO₄²⁻ ions calculated by the Robinson-Stokes method are little changed by pressure and/or temperature. The dissociation constants of Ca²⁺SO₄²⁻ and Mg²⁺SO₄²⁻ ion-pairs are increased by pressure and decreased by temperature. The thermodynamic parameters, n, ΔS°, ΔH° and ΔF°, are calculated from the coefficients of pressure and temperature of the dissociation constants. The closest approach distances of the ion-pairs are also estimated by using the theoretical equation of Fuoss. These ion-pairs would be solvent-separated ones, containing some water molecules between the cation and anion, and approach contact ones, liberating the water molecules with increasing temperature.

Introduction

From the measurements of the conductances of electrolytes, the information on the behaviors of both free ions and ion-pair is obtained. The limiting equivalent conductance γ', which is specific to the individual ions, is an important quantity to study the ion-solvent interaction. In order to know the effect of pressure on the solvation of ions, we have determined the values of γ' of 2–2 electrolytes under high pressure.

The dissociation constants of the ion-pairs have been obtained under high pressure for many electrolytes in water. Many of them increase as pressure increases 1), but some decrease or remain constant 2). The molecular structures of the ion-pairs in aqueous solution have been examined with many different techniques 3,4), which has suggested that the association of divalent metal sulphates would take place through two or more interposed water molecules. However, the effect of pressure on the structure of the ion-pair was elucidated only in the case of [Co(NH₃)₆]²⁺·SO₄⁻⁶⁻.

In this paper, the pressure and temperature effects on hydration numbers of free ions and the structures of the ion-pairs of the 2-2 electrolytes, CaSO₄ and MgSO₄, in water have been examined up to 1,200 kg/cm² at the temperatures of 15, 25 and 40°C.

**Experimental**

The conductivity cell used for high pressures was a syringe-type cell of glass and platinum, as shown in Fig. 1 (a). The oil pressure in the pressure vessel was transmitted to the sample solution by the glass piston of the syringe. The platinum electrodes in the cell were lightly coated with platinum black to avoid polarization. The cell constant $K_{cell}$ was determined by aqueous KCl solution of $10^{-2}$N. The pressure-generating apparatus is shown in Fig. 1 (b). The Bourdon-type gauge was calibrated with a free piston-type gauge. The resistance $R$ was measured by the Vanagimoto MV-7-type a.c. bridge.

![Fig. 1 Experimental apparatus](image)

The conductivity water was repeatedly distilled and in equilibrium with air. The $1,000 \times 10^{-3} \text{M}$ stock solutions of CaSO₄ and MgSO₄ were prepared from the analytical grade reagents. The solutions in the concentration range of $10^{-1} \sim 10^{-3} \text{M}$ were prepared by diluting the stock solutions with the conductivity water. The concentrations of these dilute solutions at high pressure were corrected with the volume of water at the corresponding pressure calculated by the Tait equation.

The Review of Physical Chemistry of Japan Vol. 42 No. 1 (1972)

Electrical Conductivity of CaSO₄ in Aqueous Solution under High Pressure

\[
\frac{V(0) - V(P)}{V(P)} = C \log \frac{B + P}{B + 1}. \tag{1}
\]

where \( B \) and \( C \) are the characteristic parameters of water.

The specific conductivity of the solution \( \kappa \) is defined by Eq. (2),

\[
\kappa = \frac{\kappa_{\text{sol}}}{R}. \tag{2}
\]

By subtracting from \( \kappa \) the specific conductivity of water \( \kappa'' \) (at 25°C, \( 1.19 \times 10^{-8} \text{ohm}^{-1} \text{cm}^{-1} \) at 1 atm and \( 1.94 \times 10^{-8} \text{ohm}^{-1} \text{cm}^{-1} \) at 1,200 kg/cm²), the equivalent conductance \( \Lambda \) is obtained by Eq. (3),

\[
\Lambda = \frac{1000(\kappa - \kappa'')}{C}, \tag{3}
\]

where \( C \) is the corrected equivalent concentration.

Results and Consideration

Pressure dependence of \( \Lambda \)

The plots of \( \Lambda \) against \( C^{1/2} \) have Kohlrausch's linear relation at each pressure and temperature, as shown in Fig. 2. The limiting equivalent conductance \( \Lambda' \) is determined by the extrapolation of the \( \Lambda \sim C^{1/2} \) curve to zero concentration. Table 1 shows the values of \( \Lambda \) and \( \Lambda' \) obtained at each concentration, temperature, and pressure. The pressure dependence of \( \Lambda \) is shown in Fig. 3, where an up-
arrow, ↑ indicates the maximum point of $A$. The maximum of $A$ shifts to a higher pressure as the concentration increases. The pressure dependence of $A'$ at each temperature is shown in Fig. 4. The

Electrical Conductivity of CaSO₄ in Aqueous Solution under High Pressure

Now, in the case of the dissociation of the symmetrical electrolyte (\( z_+ = z_- \)) into its free ions, the specific conductivity of the electrolyte, \( \kappa - \kappa^o \), is given by Eq. (4),

\[
10^9 (\kappa - \kappa^o) = \sum C_i \lambda_i = C \alpha \sum \lambda_i.
\]

where \( C_i \) and \( \lambda_i \) are the equivalent concentration and equivalent conductance of \( i \)-ion, respectively and \( \alpha \) the degree of dissociation. From Eqs. (3) and (4),

\[
A = \alpha \sum \lambda_i,
\]

that is, the equivalent conductance is proportional to the degree of dissociation and the sum of the ionic conductances. Therefore, the shift of \( P(A) \), the pressure of the maximum \( A \), to a higher pressure with the increase of the concentration is ascribed to the fact that the pressure coefficient of \( \alpha \) is more effective for \( A \) in the lower dilute solution than in the higher.

The pressure dependence of \( A^o \) would be explained qualitatively by Stokes' law,

\[
\lambda^o = \frac{1}{6 \pi \eta r^o},
\]

where \( \lambda^o \), \( z_i \) and \( r_i \) are the limiting ionic equivalent conductance of \( i \)-ion, its ionic valence and its Stokes radius, respectively, and \( F \) the Faraday constant, \( e \) the electronic charge, and \( \eta^o \) the viscosity of water. The viscosity of water has a minimum against pressure at lower temperatures, because the structure of water would be broken down by pressure. The minimum point disappears at about 36°C above which the viscosity increases monotonously with increasing pressure. The pressures at the minimum \( \eta^o \), \( P(\eta^o) \) are 950 kg/cm² at 15°C and 600 kg/cm² at 25°C. When the hydrated ion with the constant effective radius migrates in a continuous medium whose viscosity is \( \eta^o \) under pressure, \( P(A^o) \) should be equal to \( P(\eta^o) \) according to Eq. (6). As shown in Fig. 4, this is not the case; \( P(A^o) \) is higher than \( P(\eta^o) \) at each temperature. The maximum point of \( A^o \) is found even at 40°C, where the viscosity of water increases monotonously with increasing pressure. These discrepancies would be explained from the view point of the decrease in the radius of the hydrated ion by pressure according to the Robinson-Stokes method, though there have been other standpoints of the local viscosity in the vicinity of the ion and of the effect of dielectric relaxation on ionic motion.

Hydration numbers of the free ions

8) L. Hauser, Ann. Phys., 5, 597 (1901)

10) K. E. Bett and J. B. Cappi, Nature, 207, 620 (1965)
11) J. B. Cappi, Ph. D. Thesis, London University (1964)
12) M. Nakahara, K. Shimizu and J. Osugi, This Journal, 40, 1 (1970)
13) R. L. Kay and D. F. Evans, J. Phys. Chem., 70, 2321 (1966)
14) R. Zwanzig, J. Chem. Phys., 38, 1603 (1963)
15) R. Fernandez-Prim and G. Atkinson, J. Phys. Chem., 75, 239 (1971)
The Robinson-Stokes method has been applied to calculate the hydration number of Ca\(^{2+}\), Mg\(^{2+}\) and SO\(_4^{2-}\) ions under high pressure as follows:

\[
\lambda(p) = \lambda(p)\cdot t'(p) \quad (7)
\]

where \(t'(p)\) is the limiting transference number of i-ion at pressure \(P\). It is assumed that \(t'(p) = t'(1)\). The values of the cationic transference number are as follows:

| Temp (°C) | Ca\(^{2+}\) | Mg\(^{2+}\) |
|----------|-------------|-------------|
| 15        | 0.427       | 0.426       |
| 25        |             |             |
| 40        | 0.419       |             |
| 25         | 0.399       |             |

where \(\lambda'(1)\) were cited from the literature. From Eqs. (6) and (7), the Stokes radius \(r_s\) is obtained. Introducing the correction factor \(f_{R-S}\) for \(r_s\), the effective radius of hydrated ion \(r_e\) is obtained. The volume of the hydration sheath in the neighborhood of the ion is

\[
V = \frac{4}{3}\pi(r_e^3 - r_c^3) \quad (9)
\]

where \(r_c\) is the crystal radius of i-ion. Then the hydration number is given by the equation,

\[
h = \frac{V}{V_w} \quad (10)
\]

where \(V_w\) is the average volume of one water molecule in the hydration sheath and was assumed to be equal to that of the bulk water at each pressure. These numerical values of \(\lambda', f_{R-S}, r_e\) and \(h\) are listed in Table 2. As shown in Table 2, the hydration numbers of Ca\(^{2+}\), Mg\(^{2+}\) and SO\(_4^{2-}\) ions are invariant within the experimental error as temperature increases. Also, the hydration numbers of these ions are little changed by pressure as in the case of [Co(NH\(_3\))\(_6\)]\(^{3+}\) and SO\(_4^{2-}\) ions. This is not in agreement with Horne's opinion of the dehydration of ions by pressure.

**Dissociation of the ion-pairs**

The ion-pairs of Ca\(^{2+}\).SO\(_4^{2-}\) and Mg\(^{2+}\).SO\(_4^{2-}\) would be in equilibrium with their free ions,

\[
M^{2+}\cdot SO_4^{2-} \rightleftharpoons M^{2+} + SO_4^{2-} \quad (11)
\]

where \(M^{2+}\) represents the metal ion and \(n\) is the stoichiometric molar concentration. Then the dissociation constant \(K\) in the system of Eq. (11) is defined as follows,

\[
K = \frac{m\alpha^2 f_1 f_3}{(1-\alpha) f_2} \quad (12)
\]

where \( f_1, f_2 \) and \( f_3 \) are the activity coefficients of \( \text{M}^{2+}, \text{SO}_4^{2-} \) and \( \text{M}^{2+}\cdot\text{SO}_4^{2-} \), respectively. In the dilute solution, the activity coefficients, \( f_1 \) and \( f_2 \), are calculated from the Debye-Hückel limiting equation \( \text{(13)} \):

\[
-\log f_i = z_i^2 \frac{1.291 \times 10^8}{(D T)^{1/2}} \Gamma^{1/2},
\]

where \( \Gamma \) is the ionic concentration \( \sum z_i \), \( D \) the dielectric constant of water and \( T \) the absolute temperature, and the activity coefficient of \( \text{M}^{2+}\cdot\text{SO}_4^{2-}, f_3 \) is assumed to be unity. Using the Onsager theoretical equation \( \text{(14)} \) for the equivalent ionic conductance in the right of Eq. \( (5) \), we obtain

\[
A = a (A' - 4S\sqrt{m}) ,
\]

where \( S \) is the function of \( D, \eta' \) and \( A' \). The values of \( a \) in Eq. \( \text{(14)} \) is solved by means of successive approximation. The dielectric constant of water at pressure \( P \), \( D(P) \) is determined from the Owen-Brinkley equation \( \text{(15)} \):

\[
1 - \frac{D(P)}{D(0)} = AD(0) \log \frac{B + P}{B + 1},
\]

where \( A \) and \( B \) are characteristic parameters of water. The viscosity data are graphically interpolated values from the measurements of Cappi \( \text{(15)} \). The dissociation constant \( K \) thus determined from Eqs. \( \text{(12)}, \text{(13)} \) and \( \text{(14)} \) at each pressure and temperature are listed in Table 3.

The dissociation constant increases with increasing pressure at each temperature. When the dissociation constant of the ion-pair, \( \text{Ca}^{2+}\cdot\text{SO}_4^{2-} \) is compared with that of the ion-pair, \( \text{Mg}^{2+}\cdot\text{SO}_4^{2-} \) at

25°C, the former is smaller at each pressure. It was observed by Kuntz and Fuoss \textsuperscript{20)} that in NaCl, KCl and RbCl solutions, the larger the crystal radius of a cation is, the smaller the dissociation constant. Figs. 5 and 6 show the variation of \(\log K\) with pressure and temperature, respectively. From these plots, the thermodynamic parameters concerning the dissociation of the ion-pair (Eq. (11)) were calculated from the following relations,

\[
\Delta G^o = -RT \ln K .
\]  
\[
\left( \frac{\partial \ln K}{\partial P} \right) = -\frac{\Delta V^o}{RT} .
\]
\[
\left( \frac{\partial \ln K}{\partial (1/T)} \right) = -\frac{\Delta H^o}{R} .
\]
\[
\Delta S^o = \frac{\Delta H^o - \Delta G^o}{T} .
\]

The derived thermodynamic parameters are given in Table 4. Our value of \(\Delta V^o\) in the dissociation of \(\text{Mg}^{2+}\cdot\text{SO}_4^{2-}\) at 25°C, \(-7.7\) cc/mole, is in good agreement with Fisher's value, \(-7.3\pm0.4\) cc/mole \textsuperscript{26)}. The negative values of \(\Delta V^o\), \(\Delta H^o\) and \(\Delta S^o\) would be due to the change of hydration number and the

The closest approach distance, a, is obtained by putting the dissociation constant in this experiment into the theoretical equation of Fuoss:

\[ K = \frac{3000}{4\pi N A^2} \exp \left( -\frac{z_+ z_- e^2}{aDkT} \right) \]

where \( k \) is the Boltzmann constant and \( N \) Avogadro's number. The results are listed in Table 5. At 40°C the closest approach distance gradually decreases with increasing pressure, but at other temperatures the systematic changes by pressure are not observed. The bulk dielectric constant was used for the calculation of the closest approach distance. In the vicinity of the ion, the dielectric constant would be smaller than that of bulk water, as the dipoles of the water molecules in the vicinity of the ion are oriented by electrostrictive force. Using the effective dielectric constant, the values of the closest approach distance would become larger than those in Table 5. Therefore, the closest approach distances at 15 and 25°C in aqueous solution would be larger than the sum of the crystal radii cited in Table 5 and also at 40°C those may be somewhat larger. Hence, the ion-pair may contain some water molecules between the cation and anion. This is in good agreement with the result by ultrasonic absorption. The closest approach distance of the Ca²⁺·SO₄²⁻ ion-pair is smaller than that of the Mg²⁺·SO₄²⁻ ion-pair at 25°C at each pressure, in spite of the fact that the former has a larger sum of the

Table 5 Changes in the closest approach distances by pressure

| Pressure  | CaSO₄ (15°C) | CaSO₄ (25°C) | CaSO₄ (40°C) | MgSO₄ (25°C) |
|-----------|--------------|--------------|--------------|--------------|
| 1 atm     | 4.10         | 4.02         | 3.72         | 4.17         |
| 200 kg/cm²| 4.21         | 3.95         | 3.71         | 4.26         |
| 400       | 4.22         | 3.97         | 3.68         | 4.29         |
| 600       | 4.19         | 3.95         | 3.55         | 4.23         |
| 800       | 4.34         | 3.97         | 3.53         | 4.19         |
| 1,000     | 4.35         | 4.03         | 3.50         | 4.17         |
| 1,200     | 4.42         | 4.10         | 3.50         | 4.19         |

Sum of the crystal radii: 3.72 3.38

crystal radii. This corresponds to the larger value of \(|\Delta V^0|\) of the Ca²⁺·SO₄²⁻ ion-pair than that of the Mg²⁺·SO₄²⁻ ion-pair and to the smaller hydration number of Ca²⁺ than that of Mg²⁺. These would mean that the Ca²⁺·SO₄²⁻ ion-pair has less number of water molecules between the cation and anion than the Mg²⁺·SO₄²⁻ ion-pair. The closest approach distance decreases with increasing temperature in Ca²⁺·SO₄²⁻ ion-pair as in the case of \([\text{Co(NH}_3]_6\text{³⁺·SO}_4^2⁻\). That is, the ion-pair would gradually approach to contact one with increasing temperature.²⁹,³⁰
