The confusion and ambiguity encountered by students, in understanding virtual displacement and virtual work, is discussed in this article. A definition of virtual displacement is presented that allows one to express them explicitly for holonomic (velocity independent), non-holonomic (velocity dependent), scleronomous (time independent) and rheonomous (time dependent) constraints. It is observed that for holonomic, scleronomous constraints, the virtual displacements are the displacements allowed by the constraints. However, this is not so for a general class of constraints. For simple physical systems, it is shown that, the work done by the constraint forces on virtual displacements is zero. This motivates Lagrange’s extension of d’Alembert’s principle to system of particles in constrained motion. However a similar zero work principle does not hold for the allowed displacements. It is also demonstrated that d’Alembert’s principle of zero virtual work is necessary for the solvability of a constrained mechanical problem. We identify this special class of constraints, physically realized and solvable, as the ideal constraints. The concept of virtual displacement and the principle of zero virtual work by constraint forces are central to both Lagrange’s method of undetermined multipliers, and Lagrange’s equations in generalized coordinates.

Keywords: d’Alembert’s principle, Lagrangian mechanics, Lagrange’s equations, Virtual work, Holonomic, Non-holonomic, Scleronomous, Rheonomous constraints

I. INTRODUCTION

Almost all graduate level courses in classical mechanics include a discussion of virtual displacement, and Lagrangian dynamics. From the concept of zero work by constraint forces on virtual displacement, the Lagrange’s equations of motion are derived.

However, the definition presented in most accessible texts often seem vague and ambiguous to students. Even after studying the so called definition, it is rather commonplace that a student fails to identify, whether a supplied vector is suitable as a virtual displacement, for a given constrained system. Though some of the more advanced and rigorous treatises present a more precise and satisfactory treatment, they are often not easily comprehensible to most students. In this article we attempt a simple, systematic and precise definition of virtual displacement, which clearly shows the connection between the constraints and the corresponding allowed and virtual displacements. This definition allows one to understand how far the virtual displacement is ‘arbitrary’ and how far it is ‘restricted’ by the constraint condition.

There are two common logical pathways of arriving at Lagrange’s equation.

1. Bernoulli’s principle of virtual velocity (1717), d’Alembert’s principle of zero virtual work (1743), Lagrange’s generalization of d’Alembert’s principle to constrained system of moving particles, and Lagrange’s equations of motion (1788).

2. Hamilton’s principle of least action (1834), and variational approach to Lagrange’s equation.

The two methods are logically and mathematically independent and individually self contained. The first method was historically proposed half a century earlier, and it presents the motivation of introducing the Lagrangian as a new physical quantity. The second method starts with the Lagrangian and the related action as quantities axiomatically describing the dynamics of the system. This method is applied without ambiguity in some texts and courses. However one also finds intermixing of the two approaches in the literature and popular texts, often leading to circular definition and related confusion. A rational treatment demands an independent presentation of the two methods, and then a demonstration of their interconnection. In the present article we confine ourselves to the first method.

In this approach, due to Bernoulli, d’Alembert and Lagrange, one begins with a constrained system, defined by equations of constraints connecting positions, time and often velocities of the particles under consideration. The concept of virtual displacement is introduced in terms of the constraint equations. The external forces alone cannot maintain the constrained motion. This requires the introduction of forces of constraints. The imposition of the principle of zero virtual work by constraint forces gives us a ‘special class of systems’, that are solvable.

A proper definition of virtual displacement is necessary to make the said approach logically satisfactory. However the various definitions found in popular texts are often incomplete and contradictory with one another. These
ambiguities will be discussed in detail in the next section.

In the literature, e.g., Greenwood Eq.1.26 and Pars Eq.1.6.1, one encounters holonomic constraints of the form:

$$\phi_j(x_1, x_2, \ldots, x_{3N}, t) = 0, \quad j = 1, 2, \ldots, k. \quad (1)$$

The differential form of the above equations are satisfied by allowed infinitesimal displacements \(\{dx_i\}\), (Greenwood Eq.1.27; Pars Eq.1.6.3):

$$\sum_{i=1}^{3N} \frac{\partial \phi_j}{\partial x_i} dx_i + \frac{\partial \phi_j}{\partial t} dt = 0, \quad j = 1, 2, \ldots, k. \quad (2)$$

For a system under above constraints the virtual displacements \(\{\delta x_i\}\), satisfy the following equations (Greenwood Eq.1.28; Pars Eq.1.6.5),

$$\sum_{i=1}^{3N} \frac{\partial \phi_j}{\partial x_i} \delta x_i = 0, \quad j = 1, 2, \ldots, k. \quad (3)$$

The differential equations satisfied by allowed and virtual displacements are different even for the non-holonomic case. Here, the equations satisfied by the allowed displacements \(\{dx_i\}\) are (Goldstein Eq.2.20, Greenwood Eq.1.29 and Pars Eq.1.7.1),

$$\sum_{i=1}^{3N} a_{ji} dx_i + a_{jt} dt = 0, \quad j = 1, 2, \ldots, m. \quad (4)$$

Whereas, the virtual displacements \(\{\delta x_i\}\) satisfy (Goldstein Eq.2.21, Greenwood Eq.1.30; Pars Eq.1.7.2),

$$\sum_{i=1}^{3N} a_{ji} \delta x_i = 0, \quad j = 1, 2, \ldots, m. \quad (5)$$

Thus, there appear in the literature certain equations, namely Eq. and Eq., which are always satisfied by the not so precisely defined virtual displacements. It may be noted that these equations are connected to the constraints but are not simply the infinitesimal forms of the constraint equations, i.e., Eqs. and 11. This fact is well documented in the literature. However, the nature of the difference between these sets of equations, i.e., Eqs. and 11 on one hand and Eqs. and 11 on the other, and their underlying connection are not explained in most discussions. One may consider Eq. or Eq. as independent defining equation for virtual displacement. But it remains unclear as to how, the virtual displacements \(\{\delta x_i\}\) defined by two different sets of equations for the holonomic and the non-holonomic cases, viz., Eq. and Eq., correspond to the same concept of virtual displacement.

We try to give a physical connection between the definitions of allowed and virtual displacements for any given set of constraints. The proposed definition of virtual displacement (Sec.IIA) as difference of two unequal allowed displacements (satisfying Eq. or Eq.) over the same time interval; automatically ensures that virtual displacements satisfy Eq. and Eq. for holonomic and non-holonomic systems respectively. We show that in a number of natural systems, e.g., pendulum with fixed or moving support, particle sliding along stationary or moving frictionless inclined plane, the work done by the forces of constraint on virtual displacements is zero. We also demonstrate that this condition is necessary for the solvability of a constrained mechanical problem. Such systems form an important class of natural systems.

A. Ambiguity in virtual displacement

In the literature certain statements appear in reference to virtual displacement, which seem confusing and mutually inconsistent, particularly to a student. In the following we present few such statements found in common texts.

1. It is claimed that (i) a virtual displacement \(\delta r\) is consistent with the forces and constraints imposed on the system at a given instant; (ii) a virtual displacement is an arbitrary, instantaneous, infinitesimal change of position of the system compatible with the conditions of constraint; (iii) virtual displacements are, by definition, arbitrary displacements of the components of the system, satisfying the constraint; (iv) virtual displacement does not violate the constraint; (v) we define a virtual displacement as one which does not violate the kinematic relations; (vi) the virtual displacements obey the constraint on the motion. These statements imply that the virtual displacements satisfy the constraint conditions, i.e., the constraint equations. However this is true only for holonomic, scleronemous constraints. We shall show that for non-holonomic constraints, or scleronemous constraints, e.g., a pendulum with moving support, this definition violates the zero virtual work principle.

2. It is also stated that (i) virtual displacements do not necessarily conform to the constraints; (ii) the virtual displacements \(\delta q\) have nothing to do with actual motion. They are introduced, so to speak, as test quantities, whose function it is to make the system reveal something about its internal connections and about the forces acting on it; (iii) the word “virtual” is used to signify that the displacements are arbitrary, in the sense that they need not correspond to any actual motion executed by the system; (iv) it is not necessary that if (virtual displacement) represents any actual motion of the system; (v) it is not intended to say that such a displacement (virtual) occurs during the motion of the particle considered, or even that it could occur; (vi) virtual displacement is any arbitrary infinitesimal displacement not necessarily along the constrained path.
From the above we understand that the virtual displacements do not necessarily satisfy the constraint equations, and they need not be the ones actually realized. We shall see that these statements are consistent with physical situations, but they cannot serve as a satisfactory definition of virtual displacement. Statements like: “not necessarily conform to the constraints” or “not necessarily along the constrained path” only tell us what virtual displacement is not, they do not tell us what it really is. Reader should note that there is a conflict between the statements quoted under items 1 and 2.

Thus it is not clear from the above, whether the virtual displacements satisfy the constraints, i.e., the constraint equations, or they do not.

3. It is also stated that (i) virtual displacement is to be distinguished from an actual displacement of the system occurring in a time interval \( \Delta t \); (ii) it is an arbitrary, instantaneous, change of position of the system; (iii) virtual displacement \( \delta r \) takes place without any passage of time; (iv) virtual displacement has no connection with the time - in contrast to a displacement which occurs during actual motion, and which represents a portion of the actual path; (v) one of the requirements on acceptable virtual displacement is that the time is held fixed. We even notice equation like: \( \delta x_i = dx_i \) for \( dt = 0 \).\( ^{10} \)

The above statements are puzzling to a student. If position is a continuous function of time, a change in position during zero time has to be zero. In other words, this definition implies that the virtual displacement cannot possibly be an infinitesimal (or differential) of any continuous function of time. In words of Arthur Haas: since its (virtual displacement) components are thus not functions of the time, we are not able to regard them as differentials, as we do for the components of the element of the actual path.\( ^{11} \) It will be shown later (Sec.II), that virtual displacement can be looked upon as a differential. It is indeed a differential change in position or an infinitesimal displacement, consistent with virtual velocity \( \mathbf{v}_k(t) \), taken over a time interval \( dt \) (see Eq.\( ^{12} \)).

4. Virtual displacement is variously described as: arbitrary, virtual, and imaginary\( ^{1.5.6.7.9} \). These adjectives make the definition more mysterious to a student.

Together with the above ambiguities, students are often unsure whether it is sufficient to discuss virtual displacement as an abstract concept or it is important to have a quantitative definition. Some students appreciate that the virtual displacement as a vector should not be ambiguous. The principle of zero virtual work is required to derive Lagrange’s equations. For a particle under constraint this means that the virtual displacement is always orthogonal to the force of constraint.

At this stage a student gets further puzzled. Should he take the forces of constraint as supplied, and the principle of zero virtual work as a definition of virtual displacement? In that case the principle reduces merely to a definition of a new concept, namely virtual displacement. Or should the virtual displacement be defined from the constraint conditions independently? The principle of zero virtual work may then be used to obtain the forces of constraint. These forces of constraint ensure that the constraint condition is maintained throughout the motion. Hence it is natural to expect that they should be connected to and perhaps derivable from the constraint conditions.

II. VIRTUAL DISPLACEMENT AND FORCES OF CONSTRAINT

A. Constraints and Virtual displacement

Let us consider a system of constraints that are expressible as equations involving positions and time. They represent some geometric restrictions (holonomic) either independent of time (scleronomous) or explicitly dependent on it (rheonomous). Hence for a system of \( N \) particles moving in three dimensions, a system of \((s)\) holonomic, rheonomous constraints are represented by functions of \( \{r_k\} \) and \((t)\),

\[
f_i(r_1, r_2, \ldots, r_N, t) = 0, \quad i = 1, 2, \ldots, s. \tag{6}
\]

The system may also be subjected to non-holonomic constraints which are represented by equations connecting velocities \( \{v_k\} \), positions \( \{r_k\} \) and time \((t)\).

\[
\sum_{k=1}^{N} A_{ik} \cdot v_k + A_{it} = 0, \quad i = 1, 2, \ldots, m, \tag{7}
\]

where \( \{A_{ik}\} \) and \( \{A_{it}\} \) are functions of positions \( \{r_1, r_2, \ldots, r_N\} \) and time \((t)\). The equations for non-holonomic constraints impose restrictions on possible or allowed velocity vectors \( \{v_1, v_2, \ldots, v_N\} \), for given positions \( \{r_1, r_2, \ldots, r_N\} \) and time \((t)\). The holonomic constraints given by Eq.\((6)\), are equivalent to the following equations imposing further restriction on the possible or allowed velocities.

\[
\sum_{k=1}^{N} \left( \frac{\partial f_i}{\partial r_k} \right) \cdot v_k + \frac{\partial f_i}{\partial t} = 0, \quad i = 1, 2, \ldots, s. \tag{8}
\]

For a system of \( N \) particles under \((s)\) holonomic and \((m)\) non-holonomic constraints, a set of vectors \( \{v_1, v_2, \ldots, v_N\} \) satisfying Eq.\((7)\) and Eq.\((8)\) are called allowed velocities. It is worth noting at this stage that there are many, in fact infinitely many, allowed velocities, since we have imposed only \((s + m)\) number of scalar constraints, Eq.\((7)\) and Eq.\((8)\), on \((3N)\) scalar components of the allowed velocity vectors.
At any given instant of time, the difference of any two such non-identical allowed sets of velocities, independently satisfying the constraint conditions, are called virtual velocities.

\[ \delta v_k(t) = v_k(t) - v'_k(t) \quad k = 1, 2, \ldots, N. \]

An infinitesimal displacement over time \((t, t + dt)\), due to allowed velocities, will be called the allowed infinitesimal displacement or simply allowed displacement.

\[ dr_k = v_k(t)dt, \quad k = 1, 2, \ldots, N. \quad (9) \]

Allowed displacements \(\{dr_k\}\) together with differential of time \((dt)\) satisfy the infinitesimal form of the constraint equations. From Eq. (8) and Eq. (7), we obtain,

\[ \sum_{k=1}^{N} \left( \frac{\partial f_i}{\partial r_k} \right) \cdot dr_k + \frac{\partial f_i}{\partial t} dt = 0, \quad i = 1, 2, \ldots, s, \quad (10) \]

\[ \sum_{k=1}^{N} A_{ik} \cdot dr_k + A_{it} dt = 0, \quad i = 1, 2, \ldots, m. \quad (11) \]

As there are many independent sets of allowed velocities, we have many allowed sets of infinitesimal displacements. We propose to define virtual displacement as the difference between any two such (unequal) allowed displacements taken over the same time interval \((t, t + dt)\),

\[ \delta r_k = dr_k - dr'_k, \quad k = 1, 2, \ldots, N. \quad (12) \]

Thus virtual displacements are infinitesimal displacements over time interval \(dt\) due to virtual velocity \(\vec{v}_k(t)\),

\[ \delta r_k = \vec{v}_k(t)dt = (v_k(t) - v'_k(t))dt, \quad k = 1, 2, \ldots, N. \quad (13) \]

This definition is motivated by the possibility of (i) identifying a special class of ‘ideal constraints’ (Sec.IIC), and (ii) verifying ‘the principle of zero virtual work’ in common physical examples (Sec.III). It may be noted that, by this definition, virtual displacements \(\{\delta r_k\}\) are not instantaneous changes in position in zero time. They are rather smooth, differentiable objects.

The virtual displacements thus defined, satisfy the homogeneous part of the constraint equations, i.e., Eq. (10) and Eq. (11) with \(\partial f_i/\partial t = 0\) and \(A_{it} = 0\). Hence,

\[ \sum_{k=1}^{N} \frac{\partial f_i}{\partial r_k} \cdot \delta r_k = 0, \quad i = 1, 2, \ldots, s, \quad (14) \]

\[ \sum_{k=1}^{N} A_{ik} \cdot \delta r_k = 0, \quad i = 1, 2, \ldots, m. \quad (15) \]

The logical connection between the equations of constraint, equations for allowed displacements and equations for virtual displacements are presented in FIG 1.

The absence of the \((\partial f_i/\partial t)\) and \(A_{it}\) in the above equations, Eq. (14) and Eq. (15), gives the precise meaning to the statement: “virtual displacements are the allowed displacements in the case of frozen constraints”. The constraints are frozen in time in the sense that we make the \((\partial f_i/\partial t)\) and \(A_{it}\) terms zero, though the \(\partial f_i/\partial r_k\) and \(A_{ik}\) terms still involve both position \(\{r_1, r_2, \ldots, r_N\}\), and time \((t)\). In the case of stationary constraints, i.e., \(f_i(r_1, \ldots, r_N) = 0\), and \(\sum_{k=1}^{N} A_{ik}(r_1, \ldots, r_N) \cdot v_k = 0\), the virtual displacements are identical with allowed displacements as \((\partial f_i/\partial t)\) and \(A_{it}\) are identically zero.

**B. Existence of forces of constraints**

In the case of an unconstrained system of \(N\) particles described by position vectors \(\{r_k\}\) and velocity vectors \(\{v_k\}\), the motion is governed by Newton’s Law,

\[ m_l a_k = F_k (r_l, v_l, t), \quad k, l = 1, 2, \ldots, N \quad (16) \]

where \(m_k\) is the mass of the \(k^{th}\) particle, \(a_k\) is its acceleration and \(F_k\) is the total external force acting on it. However, for a constrained system, the equations of constraint, namely Eq. (8) and Eq. (7), impose the following restrictions on the allowed accelerations,

\[ \sum_{k=1}^{N} \frac{\partial f_i}{\partial r_k} a_k + \sum_{k=1}^{N} \frac{d}{dt} \left( \frac{\partial f_i}{\partial r_k} \right) v_k + \frac{d}{dt} \left( \frac{\partial f_i}{\partial t} \right) = 0, \quad i = 1, 2, \ldots, s \quad (17) \]

\[ \sum_{k=1}^{N} A_{ik} \cdot a_k + \frac{d}{dt} A_{ik} \cdot v_k + \frac{d}{dt} A_{it} = 0, \quad i = 1, 2, \ldots, m. \quad (18) \]
Given \( \{r_k\} \), \( \{v_k\} \) one is no longer free to choose all the accelerations \( \{a_k\} \) independently. Therefore in general the accelerations \( \{a_k\} \) allowed by Eq. 17, Eq. 18 are incompatible with Newton’s Law, i.e., Eq. 10.

This implies that during the motion the constraint condition cannot be maintained by the external forces alone. Physically some additional forces, e.g., normal reaction from the surface of constraint, tension in the pendulum string, come into play to ensure that the constraints are satisfied throughout the motion. Hence one is compelled to introduce forces of constraints \( \{R_k\} \) and modify the equations of motion as,

\[
m_k a_k = F_k + R_k, \quad k = 1, 2, \ldots, N. \tag{19}
\]

**FIG. 2: Existence of constraint forces**

**FIG 2** presents the connection between the equations of constraints and forces of constraints.

Now the problem is to determine the motion of \( N \) particles, namely their positions \( \{r_k(t)\} \), velocities \( \{v_k(t)\} \) and the forces of constraints \( \{R_k\} \), for a given set of external forces \( \{F_k\} \), constraint equations, Eq. [6] and Eq. [7], and initial conditions \( \{r_k(0), v_k(0)\} \). It is important that the initial conditions are also compatible with the constraints. There are a total of \( (6N) \) scalar unknowns, namely the components of \( r_k(t) \) and \( R_k \), connected by \( (3N) \) scalar equations of motion, Eq. [17], and \( (s + m) \) equations of constraints, Eq. [6] and Eq. [7]. For \( (6N > 3N + s + m) \) we have an under-determined system. Hence to solve this problem we need \( (3N - s - m) \) additional scalar relations.

**C. Solvability and ideal constraints**

In simple problems with stationary constraints, e.g., motion of a particle on a smooth stationary surface, we observe that the allowed displacements are tangential to the surface. The virtual displacement being a difference of two such allowed displacements, is also a vector tangential to it. For a frictionless surface, the force of constraint, the so called ‘normal reaction’, is perpendicular to the surface. Hence the work done by the constraint force is zero, on allowed as well as virtual displacement.

\[
\sum_{k=1}^{N} R_k \cdot dr_k = 0, \quad \sum_{k=1}^{N} R_k \cdot \delta r_k = 0.
\]

When the constraint surface is in motion, the allowed velocities, and hence the allowed displacements are no longer tangent to the surface (see Sec.III). The virtual displacement however remains tangent to the constraint surface. As the surface is frictionless, it is natural to assume that the force of constraint is still normal to the instantaneous position of the surface. Hence the work done by normal reaction on virtual displacement is zero. However the work done by constraint force on allowed displacements is no longer zero.

\[
\sum_{k=1}^{N} R_k \cdot dr_k \neq 0, \quad \sum_{k=1}^{N} R_k \cdot \delta r_k = 0. \tag{20}
\]

In a number of physically interesting simple problems, such as, motion of a pendulum with fixed or moving support, motion of a particle along a stationary and moving slope, we observe that the above interesting relation between the force of constraint and virtual displacement holds (see Sec.III). As the \( 3N \) scalar components of the virtual displacements \( \{\delta r_k\} \) are connected by \( (s + m) \) equations, Eq. [17] and Eq. [18], only \( n = (3N - s - m) \) of these scalar components are independent. If the \( (s + m) \) dependent quantities are expressed in terms of remaining \( (3N - s - m) \) independent objects we get,

\[
\sum_{j=1}^{n} \tilde{R}_j \cdot \delta \tilde{x}_j = 0. \tag{21}
\]

where \( \{\tilde{x}_j\} \) are the independent components of \( \{r_k\} \), \( \{\tilde{R}_j\} \) are the coefficients of \( \{\delta \tilde{x}_j\} \), and are composed of different \( \{R_k\} \). Since the above components of virtual displacements \( \{\delta \tilde{x}_j\} \) are independent, one can equate each of their coefficients to zero \( (\tilde{R}_j = 0) \). This brings in exactly \( (3N - s - m) \) new scalar conditions or equations that are needed to make the system solvable (see FIG. [3]).

Thus we have found a special class of constraints, which is observed in nature (Sec.III) and which gives us a solvable mechanical system. We call this special class of constraints, where the forces of constraint do zero work on virtual displacement, i.e., \( \sum_k R_k \cdot \delta r_k = 0 \), the ideal constraint.

Our interpretation of the principle of zero virtual work, as a definition of an ideal class of constraints, agrees with Sommerfeld. In his exact words, “a general postulate of mechanics: in any mechanical systems the virtual work of the reactions equals zero. Far be it from us to want to give a general proof of this postulate, rather we regard it practically as definition of a mechanical system”.

(Boldface is added by the authors).
III. EXAMPLES OF VIRTUAL DISPLACEMENTS

A. Simple Pendulum with stationary support

The motion of a pendulum is confined to a plane and its bob moves keeping a fixed distance from the point of suspension (see FIG. 4). The equation of constraint therefore is,

\[ f(x, y, t) = x^2 + y^2 - r_0^2 = 0, \]

where \( r_0 \) is the length of the pendulum. Whence

\[ \frac{\partial f}{\partial x} = 2x, \quad \frac{\partial f}{\partial y} = 2y, \quad \frac{\partial f}{\partial t} = 0. \]

The constraint equation for allowed velocities, Eq. (8), becomes,

\[ x \cdot v_x + y \cdot v_y = 0. \]

Hence the allowed velocity \((v_x, v_y)\) is orthogonal to the instantaneous position \((x, y)\) of the bob relative to stationary support. The same may also be verified taking a plane polar coordinate.

The allowed velocities and the allowed displacements are perpendicular to the line of suspension. The virtual velocities and the virtual displacements, being the difference of two unequal allowed velocities and displacements respectively, are also perpendicular to the line of suspension.

\[ \delta r = (v(t) - v'(t))dt, \]

\[ \delta r = (v(t) - v'(t))dt. \]

Although the virtual displacement is not uniquely specified by the constraint, it is restricted to be in a plane perpendicular to the instantaneous line of suspension. Hence it is not ‘completely arbitrary’.

The ideal string of the pendulum provides a tension \((T)\) along its length, but no shear. The work done by this tension on both allowed and virtual displacements is zero,

\[ T \cdot \delta r = 0, \quad T \cdot \delta r = 0. \]

B. Simple Pendulum with moving support

Let us first consider the case when the support is moving vertically with a velocity \(u\). The motion of the pendulum is still confined to a plane. The bob moves keeping a fixed distance from the moving point of suspension (FIG. 5). The equation of constraint is,

\[ f(x, y, t) = x^2 + (y - ut)^2 - r_0^2 = 0, \]

where \( u \) is the velocity of the point of suspension along a vertical direction.

Whence

\[ \frac{\partial f}{\partial x} = 2x, \quad \frac{\partial f}{\partial y} = 2(y - ut), \quad \frac{\partial f}{\partial t} = -2u(y - ut). \]

Hence the constraint equation gives,

\[ x \cdot v_x + (y - ut) \cdot v_y - u(y - ut) = 0, \]

or,

\[ x \cdot v_x + (y - ut) \cdot (v_y - u) = 0. \]

The allowed velocities \((v_x, v_y)\) and the allowed displacements, are not orthogonal to the instantaneous position
of the bob relative to the instantaneous point of suspension \((x, y - ut)\). It is easy to verify from the above equation that the allowed velocity \(v = (v_x, v_y)\) is equal to the sum of a velocity vector \((v_x, v_y - u)\) perpendicular to the position of the bob relative to the point of suspension \((x, y - ut)\), and the velocity of the support \((0, u)\). If we denote \(v(t) = (v_x, v_y)\), \(v_\perp(t) = (v_x, v_y - u)\) and \(u = (0, u)\), then,
\[
v(t) = v_\perp(t) + u.
\]

The allowed displacements are vectors collinear to allowed velocities. A virtual displacement being the difference of two allowed displacements, is a vector collinear to the difference of allowed velocities. Hence it is orthogonal to the instantaneous line of suspension.

\[
dr = v(t)dt = v_\perp(t)dt + u dt,
\]
\[
dr' = v'(t)dt = v'_\perp(t)dt + u dt,
\]
\[
\delta r = (v(t) - v'(t))dt = (v_\perp(t) - v'_\perp(t))dt.
\]

Hence none of these allowed or virtual vectors are ‘arbitrary’.

At any given instant, an ideal string provides a tension along its length, with no shear. Hence the constraint force, namely tension \(T\), does zero work on virtual displacement.

\[
T \cdot dr = T \cdot u \ dt \neq 0, \quad T \cdot \delta r = T \cdot v_\perp \ dt = 0
\]

For the support moving in a horizontal or any arbitrary direction, one can show that the allowed displacement is not normal to the instantaneous line of suspension. But the virtual displacement, as defined in this article, always remains perpendicular to the instantaneous line of support.

C. Motion along a stationary inclined plane

Let us consider a particle sliding along a stationary inclined plane as shown in FIG. 6. The constraint here is more conveniently expressed in polar coordinates. The constraint equation is,

\[
f(r, \theta) = \theta - \theta_0 = 0
\]

where \(\theta_0\) is the angle of the slope. Hence the constraint equation for allowed velocities, Eq. (5), gives,

\[
\left(\frac{\partial f}{\partial r}\right) \cdot v + \frac{\partial f}{\partial \theta} v_\theta + \frac{\partial f}{\partial \theta} v_\theta + \frac{\partial f}{\partial v_\theta} v_\theta = 0 \cdot \dot{r} + 1 \cdot (r \dot{\theta}) + 0 = 0
\]

Hence \(\dot{\theta} = 0\), implying that the allowed velocities are along the constant \(\theta\) plane. Allowed velocity, allowed and virtual displacements are,

\[
v = \dot{r} \hat{r}, \quad dr = \dot{r} \hat{r} dt,
\]
\[
v' = r' \hat{r}, \quad dr' = r' \hat{r} dt,
\]
\[
\delta r = (v - v')dt = (\dot{r} - r') \hat{r} dt.
\]

where \(\hat{r}\) is a unit vector along the slope.

D. Motion along a moving inclined plane

For an inclined plane moving along the horizontal side (FIG. 7), the constraint is given by,

\[
\frac{x - ut}{y} = \cot(\theta_0) = 0,
\]

\[
f(x, y) = (x - ut) - \cot(\theta_0) y = 0.
\]

Whence the constraint for allowed velocities Eq. (5) becomes,

\[
(x - u) - \cot(\theta_0) y = 0.
\]
For the moving frictionless slope, the constraint force remains zero. Hence, the work done by the constraint force on virtual displacement is equal to the velocity of the plane itself \((u, 0)\).

\[
\mathbf{v}(t) = \mathbf{v}_\parallel(t) + \mathbf{u}.
\]

Allowed displacements are vectors along the allowed velocities, however the virtual displacement is still a vector along the instantaneous position of the plane.

\[
d\mathbf{r} = (\mathbf{v}_\parallel(t) + \mathbf{u})dt, \quad d\mathbf{r}' = (\mathbf{v}_\parallel'(t) + \mathbf{u})dt,
\]

\[
\delta \mathbf{r} = (\mathbf{v}(t) - \mathbf{v}'(t))dt = (\mathbf{v}_\parallel(t) - \mathbf{v}_\parallel'(t))dt.
\]

For the moving frictionless slope, the constraint force provided by the surface is perpendicular to the plane. Hence, the work done by the constraint force on virtual displacement remains zero.

\[
\mathbf{N} \cdot d\mathbf{r} \neq 0, \quad \mathbf{N} \cdot \delta \mathbf{r} = 0.
\]

**IV. LAGRANGE’S METHOD OF UNDETERMINED MULTIPLIERS**

A constrained system of particles obey the equations of motion given by,

\[
m_k \mathbf{a}_k = \mathbf{F}_k + \mathbf{R}_k, \quad k = 1, 2, \ldots, N
\]

where \(m_k\) is the mass of the \(k\)th particle, \(\mathbf{a}_k\) is its acceleration, \(\mathbf{F}_k\) and \(\mathbf{R}_k\) are the total external force and force of constraint on the \(k\)th particle. If the constraints are ideal, we can write,

\[
\sum_{k=1}^{N} \mathbf{R}_k \cdot \delta \mathbf{r}_k = 0, \quad (22)
\]

whence we obtain,

\[
\sum_{k=1}^{N} (m_k \mathbf{a}_k - \mathbf{F}_k) \cdot \delta \mathbf{r}_k = 0. \quad (23)
\]

If the components of \(\delta \mathbf{r}_k\) were independent, we could recover Newton’s Law for unconstrained system from this equation. However for a constrained system \(\delta \mathbf{r}_k\) are dependent through the constraint equations, Eq. (14) and Eq. (15), for holonomic and non-holonomic systems respectively.

\[
\sum_{k=1}^{N} \frac{\partial f_i}{\partial \mathbf{r}_k} \delta \mathbf{r}_k = 0, \quad i = 1, 2, \ldots, s \quad (14)
\]

\[
\sum_{k=1}^{N} \mathbf{A}_{jk} \cdot \delta \mathbf{r}_k = 0, \quad j = 1, 2, \ldots, m \quad (15)
\]

We multiply Eq. (14) successively by \((s)\) scalar multipliers \(\{\lambda_1, \lambda_2, \ldots, \lambda_s\}\), Eq. (15) successively by \((m)\) scalar multipliers \(\{\mu_1, \mu_2, \ldots, \mu_m\}\) and then subtract them from the zero virtual work equation, namely Eq. (22).

\[
\sum_{k=1}^{N} \left( \mathbf{R}_k - \sum_{i=1}^{s} \lambda_i \frac{\partial f_i}{\partial \mathbf{r}_k} - \sum_{j=1}^{m} \mu_j \mathbf{A}_{jk} \right) \delta \mathbf{r}_k = 0. \quad (24)
\]

These multipliers \(\{\lambda_i\}\) and \(\{\mu_j\}\) are called the Lagrange’s multipliers. Explicitly in terms of components,

\[
\sum_{k=1}^{N} \left[ R_{k,x} - \sum_{i=1}^{s} \lambda_i \frac{\partial f_i}{\partial x_k} - \sum_{j=1}^{m} \mu_j (\mathbf{A}_{jk})_x \right] \delta x_k
\]

\[
+ \sum_{k=1}^{N} [Y]_k \delta y_k + \sum_{k=1}^{N} [Z]_k \delta z_k = 0, \quad (25)
\]

where \([Y]_k\) and \([Z]_k\) denote the coefficients of \(\delta y_k\) and \(\delta z_k\) respectively.

The constraint equations, Eq. (14) and Eq. (15), allow us to write the \((s+m)\) dependent virtual displacements in terms of the remaining \(n = (3N - s - m)\) independent ones. We choose \((s+m)\) multipliers \(\{\lambda_1, \lambda_2, \ldots, \lambda_s\}\) and \(\{\mu_1, \mu_2, \ldots, \mu_m\}\), such that the coefficients of \((s+m)\) dependent components of virtual displacement vanish. The remaining virtual displacements being independent, their coefficients must vanish as well. Thus it is possible to choose \(\{\lambda_1, \lambda_2, \ldots, \lambda_s\}\) and \(\{\mu_1, \mu_2, \ldots, \mu_m\}\) such that all coefficients \([X]_k, [Y]_k, [Z]_k\) of virtual displacements \(\{\delta x_k, \delta y_k, \delta z_k\}\) in Eq. (25) vanish. Hence we can express the forces of constraint in terms of the Lagrange’s multipliers.

\[
\mathbf{R}_k = \sum_{i=1}^{s} \lambda_i \frac{\partial f_i}{\partial \mathbf{r}_k} + \sum_{j=1}^{m} \mu_j \mathbf{A}_{jk}, \quad k = 1, 2, \ldots, N \quad (26)
\]

Thus the problem reduces to finding a solution for the equations,

\[
m_k \mathbf{a}_k = \mathbf{F}_k + \sum_{i=1}^{s} \lambda_i \frac{\partial f_i}{\partial \mathbf{r}_k} + \sum_{j=1}^{m} \mu_j \mathbf{A}_{jk}, k = 1, 2, \ldots, N \quad (27)
\]

together with the equations of constraint,

\[
f_i(\mathbf{r}_1, \mathbf{r}_2, \ldots, \mathbf{r}_N, t) = 0, \quad i = 1, 2, \ldots, s \quad (6)
\]
FIG. 8: Lagrange's method of undetermined multipliers: solvability

\[ \sum_{k=1}^{N} (m_{k} \ddot{r}_{k} - F_{k}) = 0 \]
\[ \sum_{k=1}^{N} \frac{\partial f_{i}}{\partial r_{k}} \delta r_{k} = 0, \quad i = 1, 2, \ldots, s \]
\[ \sum_{k=1}^{N} A_{ik} \cdot \delta r_{k} = 0, \quad i = 1, 2, \ldots, m \]

Lagrange's equations (method of undetermined multipliers)

\[ m_{k} \ddot{r}_{k} = F_{k} + \sum_{i=1}^{s} \lambda_{i} \frac{\partial f_{i}}{\partial r_{k}} + \sum_{j=1}^{m} \mu_{j} A_{ij}, \quad k = 1, 2, \ldots, N \]
\[ f_{i}(r_{1}, r_{2}, \ldots, r_{N}, t) = 0, \quad i = 1, 2, \ldots, s \]
\[ \sum_{k=1}^{N} A_{ik} \cdot \dot{v}_{k} + A_{i0} = 0, \quad i = 1, 2, \ldots, m \]

No. of unknowns = No. of Eq.s

Unknown quantities No. of scalar components
\( r_{i} \) \( 3N \)
\( \lambda_{i} \) \( s \)
\( \mu_{j} \) \( m \)

Here we have to solve \((3N + s + m)\) scalar equations involving \((3N + s + m)\) unknown scalar quantities, namely \(\{x_{k}, y_{k}, z_{k}, \lambda_{i}, \mu_{j}\}\) (see FIG. 5). After solving this system of equations for \(\{x_{k}, y_{k}, z_{k}, \lambda_{i}, \mu_{j}\}\), one can obtain the forces of constraint \(\{R_{k}\}\) using Eq. (26).

**V. LAGRANGE’S EQUATIONS IN GENERALIZED COORDINATES**

For the sake of completeness we discuss very briefly Lagrange’s equations in generalized coordinates. A more complete discussion can be found in most texts [1,2,3,4,5,6,7,8,9,10,11,12,13,14]. Consider a system of \(N\) particles under \((s)\) holonomic and \((m)\) non-holonomic constraints. In certain suitable cases, one can express \((s + m)\) dependent coordinates in terms of the remaining \((3N - s - m)\) independent ones. It may be noted that such a complete reduction is not possible for general cases of non-holonomic and time dependent constraints [7,14]. If we restrict our discussion to cases where this reduction is possible, one may express all the \(3N\) scalar components of position \(\{r_{1}, r_{2}, \ldots, r_{N}\}\) in terms of \((3N - s - m)\) independent parameters \(\{q_{1}, q_{2}, \ldots, q_{n}\}\) and time \((t)\).

\[ r_{k} = r_{k}(q_{1}, q_{2}, \ldots, q_{n}, t), \quad k = 1, 2, \ldots, N \]

The allowed and virtual displacements are given by,

\[ dr_{k} = \sum_{j=1}^{n} \frac{\partial r_{k}}{\partial q_{j}} dq_{j} + \frac{\partial r_{k}}{\partial t} dt, \quad k = 1, 2, \ldots, N \]
\[ \delta r_{k} = \sum_{j=1}^{n} \frac{\partial r_{k}}{\partial q_{j}} \delta q_{j}, \quad k = 1, 2, \ldots, N. \]

From Eq. (26) we obtain,

\[ \sum_{k=1}^{N} m_{k} \frac{d}{dt} \left( \sum_{j=1}^{n} \frac{\partial r_{k}}{\partial q_{j}} \frac{\partial r_{k}}{\partial q_{j}} \right) - \sum_{k=1}^{N} F_{k} \left( \sum_{j=1}^{n} \frac{\partial r_{k}}{\partial q_{j}} \delta q_{j} \right) = 0 \]

Introduce the expression of kinetic energy,

\[ T = \frac{1}{2} \sum_{k=1}^{N} m_{k} \dot{v}_{k}^{2} \]

and that of the generalized force,

\[ Q_{j} = \sum_{k=1}^{N} F_{k} \frac{\partial r_{k}}{\partial q_{j}}, \quad j = 1, 2, \ldots, n. \]

After some simple algebra one finds,

\[ \sum_{j=1}^{n} \left( \frac{d}{dt} \frac{\partial T}{\partial \dot{q}_{j}} - \frac{\partial T}{\partial q_{j}} - Q_{j} \right) \delta q_{j} = 0. \]

As \(\{q_{1}, q_{2}, \ldots, q_{n}\}\) are independent coordinates, coefficient of each \(\delta q_{j}\) must be zero separately. Hence (see FIG. 6),

\[ \frac{d}{dt} \frac{\partial T}{\partial \dot{q}_{j}} - \frac{\partial T}{\partial q_{j}} = Q_{j}, \quad j = 1, 2, \ldots, n. \]

These are called Lagrange’s equations in generalized coordinates. To proceed further one has to impose additional conditions on the nature of forces \(\{F_{k}\}\) or \(\{Q_{j}\}\).

In problems where forces \(\{F_{k}\}\) are derivable from a scalar potential \(V(r_{1}, r_{2}, \ldots, r_{N})\),

\[ F_{k} = -\nabla k \tilde{V}(r_{1}, r_{2}, \ldots, r_{N}), \quad k = 1, 2, \ldots, N. \]

One can obtain the generalized force as,

\[ Q_{j} = -\nabla k \tilde{V} \cdot \frac{\partial r_{k}}{\partial q_{j}} = -\frac{\partial V}{\partial q_{j}}, \quad j = 1, 2, \ldots, n. \]
At this stage one introduces d’Alembert’s principle of zero virtual work. Bernouilli (1717) and d’Alembert (1743) originally proposed this principle for a system in static equilibrium. The principle states that the forces of constraint do zero work on virtual displacement. For systems in static equilibrium, virtual displacement meant an imaginary displacement of the system that keeps its statical equilibrium unchanged. Lagrange generalized this principle to a constrained system of particles in motion. This principle is crucial in arriving at Lagrange’s equation. However, most texts do not clearly address the questions, (i) why one needs to extend d’Alembert’s principle to particles in motion, and (ii) why the work done by constraint forces on virtual displacements, and not on allowed displacements, is zero?

In the present article the allowed infinitesimal displacements are defined as ones that satisfy the infinitesimal form of the constraint equations. They are the displacements that could have been possible if only the constraints were present. Actual dynamics, under the given external forces, would choose one of these various sets of displacements as actual displacement of the system. The definition of virtual displacement as difference of two unequal allowed displacements over the same infinitesimal time interval \((t, t + dt)\), gives a unified definition of virtual displacement. This definition of virtual displacement satisfies the appropriate equations found in the literature, for both holonomic and non-holonomic systems.

It is shown that Newton’s equation of motion with external forces alone, is inconsistent with equations of constraint. Hence the forces of constraint are introduced. Now there are 3\(N\) equations of motion and \((s + m)\) equations of constraint involving 6\(N\) unknown scalars \(\{r_k(t), R_k\}\). Without additional condition (d’Alembert principle), the problem is underspecified and unsolvable.

It is verified that for simple physical systems, the virtual displacements, as defined in this article, satisfy d’Alembert principle for particles in motion. The rheonomous examples discussed in Sec.III show why the forces of constraint do zero work on virtual displacements and not on allowed displacements. The additional equations introduced by d’Alembert principle make the problem solvable. These justify (i) the peculiar definition of virtual displacements and the equations they satisfy, (ii) Lagrange’s extension of d’Alembert’s principle to particles in motion, (iii) why the zero work principle is related to virtual displacement and not to allowed displacement. Once the system is solvable, two methods, originally proposed by Lagrange can be used, and are demonstrated. For Lagrange’s method of undetermined multipliers, one solves \((3N - s)\) equations to obtain the time evolution of the generalized coordinates \(\{q_j = q_j(t), j = 1, \ldots, 3N - s\}\). This gives the complete description of

\[
\sum_{k=1}^{N} \left( m_k \ddot{r}_k - F_k \right), \delta r_k = 0
\]

\[
\sum_{k=1}^{N} \frac{\partial f}{\partial r_k} \delta r_k = 0, \quad i = 1, 2, \ldots, s
\]
the motion \( \{ \mathbf{r}_k = r_k(q_1, q_2, \ldots, q_n, t), k = 1, \ldots, N \} \), ignoring the calculation of the constraint forces. It may be noted that about a century later Appell’s equations were introduced for efficiently solving non-holonomic systems.

It is interesting to note that both the above mentioned methods require the principle of zero virtual work by constraint forces as a crucial starting point. In the case of Lagrange’s method of undetermined multipliers we start with the ideal constraint condition Eq. (22). From there we obtain Eq. (23)-Eq. (24). Eq. (24) expresses the constraint forces in terms of Lagrange’s multipliers. For Lagrange’s equations in generalized coordinates, we start with the ideal constraint, Eq. (22). We work our way through Eq. (25), Eq. (30), Eq. (32) and finally obtain Lagrange’s equations in generalized coordinates, Eq. (35) and Eq. (37). The last figure, FIG. 10, gives the complete logical flow of this article.

Acknowledgment

Authors wish to thank Professor John D. Jackson and Professor Leon A. Takhtajan for their remarks and suggestions. They also thank Professor Sidney Drell, Professor Donald T. Greenwood and Professor Alfred S. Goldhaber for their valuable communications.

The authors gratefully acknowledge the encouragement received from Professor Max Dresden at Stony Brook. Authors have greatly benefited from the books mentioned in this article, particularly those of Arnold, Goldstein, Greenwood, Pars and Sommerfeld.

The material presented in this article was used as part of Classical Mechanics courses at Jadavpur University during 2000-2003. SR would like to thank his students A. Chakraborty and B. Mal for meaningful discussions.
