Figure S1. The choice of the relative weight ratio of GPS relative to InSAR datasets. The RMSEs of GPS horizontal (red), GPS vertical (green), and InSAR LOS displacements vary with the relative weight ratios. The gray bar shows an equivalent weight of two datasets used in the inversion.
Figure S2. The smoothing factor $\kappa$ determination using (a) the trade-off curve between the root mean square error (RMSE) and the roughness of the slip distribution model, (b) curve of the $jR_i$ values versus model roughness. The red cross corresponding to $\kappa = 2$ is the preferred smoothing factor chosen for the slip inversion.

Figure S3. Comparison of the RMSE and $jR_i$ values for the southeast dipping fault F1 and the northwest dipping fault F1.
Figure S4. Predicted vertical displacements from our preferred model and previous source models available. The white contours outline the asperities with a slip amplitude of over 2 m. The red lines denote the active faults.

Figure S5. Sensitivity test of Coulomb stress changes to effective coefficients of friction ($\mu' = 0.2, 0.4, 0.6, 0.8$) at different depths. The receiver fault is approximately paralleled to the seismogenic fault of the mainshock, with (strike, dip and rake) of (220°, 68°, -165°). Aftershocks with Mw>3.0 and hypocenter depths ranging $d \pm 2.5$ km are denoted by green circles in each panel.
Figure S6. Sensitivity test of Coulomb stress changes to receiver faults at different depths, calculated from the preferred model with $\mu' = 0.4$. Four scenarios of receiver fault parameters with $220^\circ/68^\circ/-165^\circ$ from our study, $226^\circ/84^\circ/-142^\circ$ from NIED, $222^\circ/77^\circ/-163^\circ$ from GCMT, and $224^\circ/66^\circ/-152^\circ$ from USGS W-phase are used. Aftershocks with Mw>3.0 and hypocenter depths ranging $d \pm 2.5$ km are denoted by green circles in each panel.

Figure S7. Sensitivity test of Coulomb stress changes to source models at different depths, resolved onto the receiver fault with $220^\circ/68^\circ/-165^\circ$ with $\mu' = 0.4$. Five available source models of the 2016 Kumamoto earthquake are used. Aftershocks with Mw>3.0 and hypocenter depths ranging $d \pm 2.5$ km are denoted by green circles in each panel. The white contours highlight the asperities with a slip amplitude of over 2 m.
Figure S8. Checkerboard test for resolution of the joint or individual inversion of InSAR and GPS data. The synthetic model has a slip amplitude of either 0 or 2 m at intervals.

Figure S9. Jackknife test results of a. the mean slip, b. the standard derivation (Std.) and c, the coefficient of variation (CV) of slip.
Table S1. Source parameters of the 2016 Kumamoto earthquake from inversion of various datasets.

| Source                        | Datasets                                                                 | Segment                  | Strike (°) | Dip (°) | Rake (°) | Max slip (m) | Moment (Nm) | Mw*  |
|-------------------------------|-------------------------------------------------------------------------|--------------------------|------------|---------|----------|--------------|-------------|------|
