MicroRNA (miRNA)-guided messenger RNA (mRNA) translational repression is believed to be mediated by effector miRNA-containing ribonucleoprotein (miRNP) complexes harboring fragile X mental retardation protein (FMRP). Recent studies documented the nucleic acid chaperone properties of FMRP and characterized its role and importance in RNA silencing in mammalian cells. We propose a model in which FMRP could facilitate miRNA assembly on target mRNAs in a process involving recognition of G quartet structures. Functioning within a duplex miRNP, FMRP may also mediate mRNA targeting through a strand exchange mechanism, in which the miRNA∗ of the duplex is swapped for the mRNA. Furthermore, FMRP may contribute to the relief of miRNA-guided mRNA repression through a reverse strand exchange reaction, possibly initiated by a specific cellular signal, that would liberate the mRNA for translation. Suboptimal utilization of miRNAs may thus account for some of the molecular defects in patients with the fragile X syndrome.

THE miRNA-GUIDED RNA SILENCING MACHINERY AND DISEASES

MicroRNAs (miRNAs) are small ~21- to 24-nucleotide (nt) RNAs that mediate messenger RNA (mRNA) translational repression through recognition of specific partially complementary binding sites usually located in the 3’ nontranslated region (NTR). They are generated by successive processing of stem-loop structured primary miRNAs (pri-miRNAs) and miRNA precursors (pre-miRNAs) by the ribonucleases (RNases) III Drosha [1] and Dicer [2–4], respectively, as reviewed in this issue by Ouellet et al [5]. Encoded by 1–5% of the genome in eukaryotes, miRNAs may regulate more than 30% of the genes in humans [6, 7]!

Unveiling the complexity of the process, recent studies have identified new protein components involved in miRNA-guided RNA silencing, such as DiGeorge syndrome critical region 8 (DGCR8) [8–11], transactivating response (TAR) RNA-binding protein (TRBP) [12–15], and fragile X mental retardation protein (FMRP) [16, 17]. Intriguingly, these accessory proteins, which are required for optimal functioning of the pathway, are related to specific human diseases.

Thus, in addition to the emerging causal links between defective miRNAs and human diseases, as reviewed in Ouellet et al [5] and Perron et al [18], some genetic disorders might also be related to malfunctioning of the machinery involved in miRNA biogenesis and function.

DGCR8 was identified in Drosha immunoprecipitates and found to be required for optimal pri-miRNA processing [10]. Both acting within the Microprocessor complex [10], DGCR8 has been proposed to guide Drosha in substrate recognition [11]. Clinically, patients carrying a common monoallelic deletion affecting the DGCR8 gene display phenotypes defined as the DiGeorge syndrome, with manifestations such as congenital heart defects, characteristic facial appearance, immunodeficiency, and behavioral problems [19, 20]. The possibility that the DiGeorge syndrome is caused by a perturbed Drosha function and/or pri-miRNA processing is attractive, but remains to be established.

As for TRBP, it was identified by proteomic analysis of Dicer immunoprecipitates and reported to assist Dicer function within a pre-miRNA processing complex [12, 13]. Initially identified in 1991, TRBP was characterized as a cellular factor acting in synergy with the viral Tat protein in the
transactivation of the long terminal repeat of human immunodeficiency virus type 1 (HIV-1), leading to viral gene transcription [21]. TRBP may thus play a dual role in HIV-1 pathogenesis and RNA silencing, as recently discussed [22].

Two independent groups simultaneously reported a possible relationship between the Drosophila FMRP ortholog (dFMR1) and RNA interference (RNAi). dFMR1 was found to be associated with the effector RNA-induced silencing complex (RISC) as well as miRNAs in Drosophila S2 cells [16, 17]. In mammalian cells, FMRP was reported to be part of a ribonucleoprotein (RNP) complex with Argonaute 2 (Ago2) and miRNAs [23]. These findings suggest a possible link between the loss of FMRP function in miRNA-guided RNA silencing and the fragile X syndrome.

**FMRP AS A REGULATOR OF TRANSLATION**

In humans, the FMR1 (fragile mental retardation 1) gene, which spans ~38 kb in the q27.3 region located at the tip of the X chromosome long arm, encodes an mRNA of ~3.9 kb composed of a ~0.2 kb 5′NTR, a 1.9 kb coding region, and a 1.8 kb 3′NTR [24]. Loss of the FMR1 gene product FMRP is the etiologic factor of the fragile X syndrome, the most frequent cause of inherited mental retardation [25, 26]. It affects about 1 in 4000 males, who will develop in almost all cases moderate to severe mental retardation (IQ ≤ 50), and about 1 in 7000 females, who present in general a milder mental handicap [24].

FMRP has been detected in practically every tissue in humans and rodents, with high levels in the brain, testes, esophagus, lung, and kidney [27]. The ability of FMRP to bind RNA, which was first suggested by the presence of K-homology (KH) domains and an RGG box found in various RNA-binding proteins, was later confirmed experimentally [28, 29]. FMRP is associated with translating polyribosomes in neuronal cells [30, 31] and acts, at high levels, as a negative regulator of translation in vitro and in vivo [32–34].

Experimental studies have documented the involvement of FMRP in translational control. When preincubated with mRNAs, FMRP leads to inhibition of translational inhibition both in vitro in the rabbit reticulocyte lysate system and in vivo after microinjection in the Xenopus oocytes [32, 33]. In Drosophila, the dFMR1 protein was reported to down-regulate expression of the futsch protein [35]. Expression of high levels of FMRP results in repression of reporter genes in transfected cultured mammalian cells [34]. Although FMRP has been shown to interact with mRNAs and to inhibit translation, its exact role and function are unclear.

More recently, using the recombinant protein, Gabus et al [36] have shown that FMRP possesses nucleic acid chaperone properties, shedding new light on the principal mechanism by which FMRP could regulate gene expression. They observed that FMRP could either anneal or transfer DNA strands of TAR that are perfectly complementary in vitro. Examining these activities in a hammerhead ribozyme model system, the authors noted that FMRP enhanced ribozyme cleavage of an RNA substrate. The KH motifs and RGG box were found to be important for optimal chaperone activity [36]. These findings suggest that FMRP may regulate translation by acting on the structural status of mRNAs.

Are these nucleic acid chaperone properties of FMRP compatible with, and relevant to, a specific cellular context or regulatory process, such as miRNA-guided RNA silencing?

**A ROLE FOR FMRP IN miRNA-GUIDED RNA SILENCING?**

In Drosophila S2 cells, mRNA-cleaving RNP complexes have been found to contain dFMR1 [16, 17] as well as a single siRNA strand [37, 38]. Independent groups have shown that target cleavage directed by single-stranded (ss) siRNAs is supported in extracts of HeLa cells [39, 40], from which a human RISC containing ss siRNAs was characterized [40]. In mammalian cells, FMRP was reported to be part of an miRNA-containing RNP (miRNP) complex containing Ago2 [23]. Thus, although the mammalian and fly RNA-silencing machineries differ substantially, they may share two features in common: an RNP complex containing an ssRNA species and a member of the fragile X family of proteins.

How miRNAs and ss siRNAs are used by the effector RNP complexes for recognition and targeting of regulatable mRNAs remains poorly understood. However, rather than being the result of a passive hybridization reaction, formation of an miRNA:mRNA or ss siRNA:mRNA transition complex is more likely to be facilitated by a component of the miRNP or siRNP complexes. Capable of promoting RNA folding and hybridization, FMRP represents the most interesting and valuable protein candidate.

**FMRP FACILITATES miRNA ASSEMBLY ON TARGET mRNA**

We verified this possibility and showed that human FMRP can act as an miRNA acceptor protein for Dicer and facilitate assembly of miRNAs on specific target RNA sequences (see Figures 1 and 2) [41]. In these assays, FMRP exhibited a preference for assembling imperfectly paired miRNA:mRNA duplexes, which is the most prevalent situation encountered in mammals. The miRNA assembler property of FMRP was
abrogated upon deletion of its RNA-binding KH domains [41]. In line with these findings, reporter gene silencing assays supported the involvement of FMRP in an ss siRNA-containing RNP (siRNP) effector complex and revealed its requirement for optimal RNAi in cultured mammalian cells [41]. These data suggest that FMRP may function as the miRNA assembler in RNA silencing.

**FMRP CAN EXCHANGE miRNA*/mRNA STRANDS**

Recently, native gel electrophoresis unveiled different RNP complexes containing siRNA duplexes in *Drosophila* [37, 38], leading the authors to propose a siRNP assembly scheme compatible with conversion of double-stranded (ds) siRNP into ss siRNP. mRNA cleavage activity could only be correlated with the latter complex [37]. siRNA-induced mRNA cleavage and miRNA-guided translational repression may be mediated by different RNP complexes and differ mechanistically. If ss siRNPs induce mRNA cleavage, what about the complexes that mediate inhibition of translation? Do they contain ssRNA or dsRNA, such as miRNA duplexes? In fact, duplex RNA-containing RNPs may be more than precursors of ssRNA-containing RNPs. They may be functionally important in RNA silencing. Whether they are involved in miRNA-guided translational repression has not been addressed so far.

However, this would require resolution of the “three-strand” enigma, posed by targeting of an ssRNA by dsRNA species. In that context, formation of a specific miRNA:mRNA transition complex from a miRNA:miRNA* duplex and its target RNA would appear as obligatory. Interestingly, human FMRP can do just that! We observed that FMRP can accept and utilize miRNA:miRNA* duplexes, generated upon Dicer processing of pre-miRNAs, to favor miRNA:mRNA complex formation through an miRNA*/mRNA strand exchange reaction [41], as illustrated in Figure 1. Together, these observations suggest that FMRP could facilitate mRNA targeting by acting (i) as an miRNA assembler in ssRNA-containing RNPs, and (ii) as an miRNA*/mRNA strand exchanger in duplex RNA-containing RNP effector complexes.

**IS FMRP INVOLVED IN RELIEVING mRNA REPRESSION?**

Reversibility is a fundamental difference between siRNP-mediated mRNA cleavage or miRNP-guided translational repression. If mRNA structural and functional integrity is preserved, silenced mRNAs could be translated again,
whereas degraded mRNAs could not. In *Drosophila*, the RISC mediates cleavage of the mRNA target, and is presumably regenerated, allowing for repeated cycles of mRNA inactivation and amplification of the phenomenon [43]. In contrast to the most prevalent situation in flies and plants, mammalian mRNAs are mainly and primarily subjected to miRNP-induced translation repression prior to their relocalization to specific cytoplasmic foci, referred to as processing (P-) bodies [44, 45] or GW182-containing bodies (GW-bodies) [46], where mRNA degradation occurs. This sequence of events is supported by a recent study revealing that mRNAs containing partial miRNA complementary sites are eventually targeted for degradation in vivo, as exemplified by the let-7 miRNA/miRNA complex is cleaved by Ago2 in *Drosophila* embryo lysates. How- ever, the authors showed that passenger-strand cleavage is not important for the incorporation of miRNAs that derive from mismatched duplexes [48]. These observations raise the following question: do miRNAs play a significant role in RNA silencing?

The possibility that the miRNA* could be used by FMRP like a spare RNA for the mRNA to be relieved from the miRNA repression, as illustrated in Figure 2, is plausible and attractive. Characterized as a chaperone [36], FMRP could bind to one or more nucleic acid molecules and promote the formation of the most stable structure, upon which its continued binding is no longer required to maintain it [36, 49, 50]. The results of our previous study [41] suggest that the miRNA:miRNA complex is more stable than the miRNA:miRNA* duplex. We hypothesize that unknown cellular signals or factors may assist FMRP in executing a reverse strand exchange by lowering the required thermodynamic threshold. The miRNA* may further facilitate that process by providing an appropriate sequence-specific RNA template. The reaction would liberate the miRNA for translation and lead to reconstitution of a duplex miRNP, theoretically available for subsequent rounds of mRNA regulation events.

**A ROLE FOR FMRP DEPHOSPHORYLATION IN RNA SILENCING?**

FMRP may function as a molecular device regulating mRNA translation by allowing optimal miRNA assembly or disassembly in response to specific cellular signals or factors. Posttranslational modifications, such as phosphorylation/dephosphorylation events, may regulate FMRP function in RNA silencing, allowing it, for example, to switch between the forward (on) and reverse (off) modes of RNA strand exchange. *Drosophila* FMRP1 is phosphorylated by caspase II at serine 406 (Ser406), which is highly conserved among fragile X family members from several species [51]. This residue is located in close proximity to the RGG box and corresponds to Ser499 [52] or Ser500 [51] (depending on amino acid numbering) in human FMRP, which was also found to be phosphorylated in vivo. Phosphorylation upregulated dFMR1 oligomerization, thereby enhancing the RNA-binding properties of the protein [51]. In contrast to the *Drosophila* ortholog, the phosphorylation status of mammalian FMRP did not influence its association with specific mRNAs in vivo [52]. The authors, however, found that unphosphorylated FMRP is associated with actively translating polyribosomes, while a fraction of phosphorylated FMRP is associated with apparently stalled polyribosomes [52]. These data suggest that the release of FMRP-induced translational suppression may involve a dephosphorylation signal [52].

**FMRP MAY BE A KEY DETERMINANT OF miRNA:mRNA SPECIFICITY**

The presence and importance of FMRP in effector miRNP complexes may explain why FMRP is found associated with several hundreds of different mRNAs [53]. It will be interesting to see what proportion of these mRNAs bound by FMRP [53, 54] is experimentally validated and physiologically
I. Plante and P. Provost

Figure 3: A potential role for suboptimal miRNA:mRNA assembly and/or disassembly in the etiology of the fragile X syndrome. (1) miRNA assembly on target mRNAs may be optimal when facilitated by FMRP, which may also be required for optimal relief of miRNA-guided translational repression. (2) In the absence of FMRP, suboptimal miRNA assembly on target mRNAs may lead to overexpression of specific proteins. (3) Whereas suboptimal disassembly of FMRP-deficient miRNPs from target mRNAs may result in a prolonged inhibition of translation. The resulting misbalanced expression of miRNA-regulated genes may alter downstream cellular processes and metabolic pathways (not depicted in this figure) and lead to the development of the fragile X syndrome.

relevant miRNA targets. Using a bioinformatic approach, John et al. [42] observed a strong enrichment of predicted targets in mRNAs associated with FMRP in mammals. FMRP may thus be a key determinant of miRNA:mRNA specificity. This is consistent with the hypothesis that miRNAs act as sequence-specific adaptors in the interaction of RNPs with translationally regulated mRNAs [42]. This interaction may be dictated, on the one hand, by the nucleotide sequence of the miRNA and, on the other hand, by the presence of G quartet structures [55] and/or kissing complex motifs [56] in the mRNA. Therefore, it may not be a coincidence that the FMR1 gene is highly conserved among vertebrates [27], where mRNAs are primarily subjected to miRNP-induced translation repression.

A MOLECULAR BASIS OF THE FRAGILE X SYNDROME?

The biochemical properties of FMRP make it a prime candidate for a role in mediating and relieving miRNA-guided translational repression. We hypothesize that the absence of FMRP expression may result in suboptimal miRNA assembly on, and/or disassembly from, their natural mRNA targets, leading to a perturbed protein expression profile (see Figure 3). This may be expected given the requirement of FMRP for efficient small RNA-guided gene regulation [41].

The FMRP paralog fragile X-related protein 1 (FXR1P) exhibited miRNA annealing and strand exchange properties similar to FMRP [41]. These data suggest a conserved function for fragile X proteins in RNA silencing and open the possibility that FXR1P may partly complement or compensate for the absence or loss of FMRP expression (see Figure 2).

The next challenge will be to ascertain the ability of FMRP to assemble and exchange miRNA strands in a cellular context. In fact, several additional issues need to be addressed in order to validate the proposed hypothesis. For instance, are these properties of FMRP preserved within miRNPs in vivo? What are the cellular proteins and/or cofactors assisting FMRP function in vivo? Is FMRP able to relieve miRNA-guided mRNA repression? If so, what is the mechanism of that process, that is, the sequence of events, nature of the components involved and/or signal(s) required? When and where in the cell do these events take place? Elucidation of the exact role and function of FMRP in miRNA-guided gene regulation may hold key to determining the molecular basis of the fragile X syndrome and establishing a causal link between dysfunction of the RNA-silencing machinery and a human genetic disease.
