Abstract

Well-posedness is proved for the stochastic viscous Cahn-Hilliard equation with homogeneous Neumann boundary conditions and Wiener multiplicative noise. The double-well potential is allowed to have any growth at infinity (in particular, also super-polynomial) provided that it is everywhere defined on the real line. A vanishing viscosity argument is carried out and the convergence of the solutions to the ones of the pure Cahn-Hilliard equation is shown. Some refined regularity results are also deduced for both the viscous and the non-viscous case.

AMS Subject Classification: 35K25, 35R60, 60H15, 80A22.

Key words and phrases: stochastic viscous Cahn-Hilliard equation, singular potential, well-posedness, regularity, vanishing viscosity, variational approach.

1 Introduction

The deterministic Cahn-Hilliard equation was first proposed in [6] to describe the spinodal decomposition phenomenon occurring during the phase separation in a binary metallic alloy. In order to model the dynamics of viscous phase-transitions, Novik-Cohen introduced in [54] the viscous regularization of the equation (see also [28, 29]).

The pure and viscous Cahn-Hilliard equations can be written in a unified form as

$$
\partial_t u - \Delta w = 0, \quad \bar{w} \in \varepsilon \partial_t u - \Delta u + \beta(u) + \pi(u) - g \quad \text{in} \ (0, T) \times D,
$$

where $D$ is a smooth bounded domain in $\mathbb{R}^N$ ($N = 2, 3$), $T > 0$ is a fixed finite time, $\Delta$ is the Laplace operator, $g$ is a prescribed source term and $\varepsilon$ is a nonnegative parameter: the case $\varepsilon = 0$ corresponds to the pure case, while $\varepsilon > 0$ corresponds to the viscous case. The unknowns of the equation are the order parameter $u$ and the chemical potential $\bar{w}$. As usual, $\beta$ is a maximal monotone operator and $\pi$ is a Lipschitz-continuous function on $\mathbb{R}$, so that the term $\beta + \pi$ can be interpreted as the (sub)differential of a so-called double-well potential. This can be seen as a sum $\hat{\beta} + \hat{\pi}$, where $\hat{\beta}$ is the convex part and $\hat{\pi}$ the concave perturbation: in this setting, we have $\beta = \partial \hat{\beta}$ and $\pi = \hat{\pi}'$. We refer to [17] for some concrete example of double-well potentials. Usually, the equation is complemented with homogeneous Neumann boundary conditions for both $u$ and $\bar{w}$, ensuring thus the conservation of the mean of $u$ on $D$ (as it follows directly integrating the first equation), and a given initial datum:

$$\partial_n u = \partial_n \bar{w} = 0 \quad \text{on } (0, T) \times \partial D , \quad u(0) = u_0 \quad \text{in } D ,$$

where $n$ stands for the outward normal unit vector on $\partial D$.

In the last decades, the mathematical literature on deterministic Cahn-Hilliard equations has been widely developed. Existence of solutions, continuous dependence on the data and regularity have been studied for example in [7–9, 11, 12, 17, 36] also under refined frameworks such as the dynamic boundary conditions for $u$ or $\bar{w}$. Asymptotic behaviour of the solutions have also been analyzed in [13, 20, 37]. More recently, some existence and uniqueness have been obtained when the dependence of $\bar{w}$ on the viscosity term is of nonlinear type: we mention in this direction the works [4, 53, 60]. Alongside the analysis of well-posedness for the equation, several results have also been achieved in the context of optimal control problems: we point out for example the contributions [10, 18, 19, 43].

It is well-known, however, that the deterministic model fails in taking into account the effects due to the random microscopic movements, which be of configurational, vibrational, electronic and magnetic type (see for example [21]). In order to capture the randomness of the phenomenon in the model, the most natural way is to add a cylindrical Wiener process in the first equation (see [46]), and obtain a stochastic partial differential equation in $u$. While the stochastic formulation of the problem is straightforward for the pure Cahn-Hilliard equation, due to the viscosity term we have to rearrange the system in a different way. To this end, note that if we formally substitute the second equation in the first one, the system can be written as

$$\partial_t (u - \varepsilon \Delta u) - \Delta w = 0 , \quad w \in -\Delta u + \beta(u) + \pi(u) - g ,$$

with Neumann boundary conditions for $u$ and $w$. Consequently, the stochastic formulation of the system is given by

$$d(u - \varepsilon \Delta u) - \Delta w \, dt = B(t, u) \, dW , \quad w \in -\Delta u + \beta(u) + \pi(u) - g ,$$

where $W$ is a cylindrical Wiener process on a certain Hilbert space $U$ and $B$ is a suitable operator integrable with respect to $W$.

The main motivation behind the mathematical analysis of stochastic Cahn-Hilliard equations is to provide a theoretical starting point to study further models with stochastic perturbations which are relevant in terms of applications. Among all, in the last years
there has been a growing interest in the study of phase field models for tumor growth, for example, which aim at describing the evolution of a tumoral mass within a healthy tissue according to several factors such as proliferation, apoptosis, nutrient consumption, etc. Such models usually couple a Cahn-Hilliard equation for the tumoral fraction with a reaction-diffusion equation for the nutrient: see for example [23,35,41,42,55] for the model derivation and [14,16,31,34] (and the references therein) for studies on well-posedness and optimal control. While in the deterministic setting such models have received much attention, we are not aware of any contribution dealing also with possible stochastic perturbations. In particular, any mathematical analysis of the stochastic counterpart would require first some solid well-posedness and regularity results for the stochastic Cahn-Hilliard equation itself, which is currently not very developed in literature. In this direction, this paper provides a starting point in terms of well-posedness and regularity for possible future studies of stochastic models involving Cahn-Hilliard equations. A joint work with C. Orrieri and E. Rocca on a stochastic version of a phase-field model for tumor growth is in preparation.

From the mathematical perspective, the stochastic Cahn-Hilliard has been studied so far mainly in the pure case $\varepsilon = 0$. Existence, uniqueness and regularity have been investigated in the works [22,24,27] for the stochastic pure Cahn-Hilliard equation with a polynomial double-well potential, and in [61] for the pure case with a possibly singular double-well potential. The reader can also refer to [1] for a study of a stochastic Cahn-Hilliard equation with unbounded noise and [25,26,38] dealing with stochastic Cahn-Hilliard equations with reflections. To the best of our knowledge, the only available results dealing with the stochastic viscous Cahn-Hilliard equation seem to be [40,44]: here, the authors prove existence of mild solution and attractors under the classical case of a polynomial double-well potential. Let us also mention, for completeness, the contributions [3] dealing with a stochastic Allen-Cahn equation with constraints, and [30] for a study of a diffuse interface model with thermal fluctuations.

The aim and novelty of this paper is to carry out a unifying and self-contained mathematical analysis of the stochastic viscous Cahn-Hilliard system, under no growth nor smoothness assumptions on the double-well potential. This is motivated by the fact that, in applications to phase-transitions, degenerate potentials (possibly defined on bounded domains) play an important role (see again [17]): consequently, from the mathematical point of view, it is worth trying to give sense to the equation with as less constraints as possible on the growth of $\beta$. In this direction, our previous contribution [61] analyzed the pure case with no growth restriction on the potential. A corresponding analysis for the viscous case is not available yet, and is performed here. More specifically, we prove well-posedness for the viscous equation under no growth nor smoothness conditions on $\beta$. The only requirement is that $\beta$ is everywhere defined on the real line: while this hypothesis is not needed in the deterministic theory, it seems to be essential in the stochastic case. Nevertheless, any order of growth for $\beta$ at infinity (even super-exponential for example) is included in our treatment. The techniques that we use are based on a generalized variational approach, which has been also employed in order to analyse singular semilinear equations (see [47,50,51]), divergence-form equations (see [48,49,52,59]), Allen-Cahn equations with dynamic boundary conditions (see [56]) and porous media equations (see [2]). The second main novelty of this paper is that we prove the convergence of solutions to the viscous Cahn-Hilliard equation to the ones of the pure equation, as the viscosity
The stochastic viscous Cahn-Hilliard equation coefficient goes to $0$. Such a convergence result is very relevant for many applications: indeed, the solutions to the viscous Cahn-Hilliard equation are much more regular and easier to handle, hence the possibility of approximating the (less regular) solutions to the pure equation can be used in practice for example in regularity problems. As an direct application of the vanishing viscosity limit, we prove some refined regularity results for the both the viscous and the pure case.

We are thus interested in studying the stochastic viscous Cahn-Hilliard equation with homogeneous Neumann boundary conditions in the following form:

\begin{align}
  d(u - \varepsilon \Delta u)(t) - \Delta w(t) \, dt &= B(t, u(t)) \, dW(t) \quad \text{in } (0, T) \times D, \quad (1.1) \\
  w \in -\Delta u + \beta(u) + \pi(u) - g \quad &\text{in } (0, T) \times D, \quad (1.2) \\
  \partial_n u = \partial_n w &= 0 \quad \text{in } (0, T) \times \partial D, \quad (1.3) \\
  u(0) &= u_0 \quad \text{in } D. \quad (1.4)
\end{align}

Let us briefly summarize the contents of the work. Section 2 contains the main hypotheses of the paper and the statement of the main results: the well-posedness of the system with both additive and multiplicative noise, the vanishing viscosity limit and the regularity results. Section 3 deals with the proof of well-posedness. The main idea is to start considering the problem with additive noise, where $\beta$ and $B$ are regularized considering the Yosida approximation and an elliptic-type approximation in space, respectively. This is solved using the classical variational approach in a Hilbert triple, with a suitable dualization chosen ad hoc. Then uniform estimates on the approximated solutions, both pathwise and in expectation, together with compactness and monotonicity arguments, provide existence of solutions to the original problem. In particular, a crucial point is to prove a generalized Itô’s formula on a certain dual space, from which a very natural continuous dependence on the initial datum follows. The generalization to the case of multiplicative noise is carried out combining a Lipschitz-type assumption on $B$ and a fixed point argument, and using a classical patching argument in time. In Section 4 we prove the asymptotic behaviour of the solutions as the viscosity coefficient goes to $0$. Again, this is carried out proving uniform estimates independent of the parameter $\varepsilon$, and the passage to the limit is performed through monotonicity techniques. Finally, Section 5 contains the proof of the regularity results: in the first one we show that additional requirements on the momentum of the data yield, in the case of the classical double-well potential, additional space-time estimates on the chemical potential and on the nonlinearity. The proof is based strongly on the Sobolev embeddings theorems and a generalized Itô’s formula for the problem. Finally, in the second regularity result the main idea is that if the data of the problem are more regular, then we are able to give appropriate sense to an Itô-type formula (better said, inequality) for the Ginzburg-Landau free-energy functional associated to the system. Starting with the viscous case, we show further uniform estimates on the solutions yielding the desired regularity result. Furthermore, passing to the limit as $\varepsilon \searrow 0$ in the estimates which are independent of the viscosity parameter yields some refined regularity properties also for the pure case thanks to the asymptotic result already proved. As a main consequence, we are able to give sufficient conditions yielding $H^3$-regularity in space for the solution.
2 General setting and main results

Let $D \subseteq \mathbb{R}^N$ ($N = 2, 3$) be a smooth bounded domain, $T > 0$ a fixed final time and set $Q := (0, T) \times D$. We shall work on an underlying filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \in [0, T]}, \mathbb{P})$ satisfying the usual conditions, i.e. the filtration is saturated and right-continuous. Moreover, $U$ is a separable Hilbert space and $W$ is a cylindrical Wiener process on $U$.

Throughout the work, the spaces of Bochner-integrable functions shall be denoted by the classical symbols $L^p(0, T; E)$ and $L^p(\Omega; E)$, where $E$ can be an arbitrary Banach space. The spaces of bounded linear operators and Hilbert-Schmidt operators are indicated by $\mathcal{L}(E_1, E_2)$ and $\mathcal{L}^2(E_1, E_2)$, respectively, where $E_1$ and $E_2$ are Hilbert spaces. Moreover, we shall denote duality pairings, scalar products and norms in Banach and Hilbert spaces with the symbols $\langle \cdot, \cdot \rangle$, $(\cdot, \cdot)$ and $\| \cdot \|$, respectively, specifying the space in consideration through a subscript.

We shall use the following definitions:

$$
H := L^2(D), \quad V_s := \begin{cases} H^s(D) \\ \{v \in H^s(D) : \partial_n v = 0 \text{ on } \partial D\} \end{cases} \quad \text{if } s \in [1, 2),
$$

$$
H := L^2(D), \quad V_s := \begin{cases} H^s(D) \\ \{v \in H^s(D) : \partial_n v = 0 \text{ on } \partial D\} \end{cases} \quad \text{if } s \geq 2.
$$

For every element $v \in V_1^*$, the mean of $v$ on $D$ is denoted by $v_D := \frac{1}{|D|} \langle v, 1 \rangle_{V_1}$, and we set

$$
V_{1,0} := \{v \in V_1^* : v_D = 0\}, \quad H_0 := \{v \in H : v_D = 0\}, \quad V_{1,0} := V_1 \cap H_0
$$

for the subspaces of $V_1^*$, $H$ and $V_1$ formed of the null-mean elements. Let us recall also that thanks to the classical elliptic regularity results for the Laplace operator and the Poincaré inequality, two equivalent norms on $V_1$ and $V_2$ are given by, respectively,

$$
\|v\|_1 := \sqrt{|v_D|^2 + \|\nabla v\|^2_H}, \quad v \in V_1, \quad \|v\|_2 := \sqrt{\|v\|^2_H + \|\Delta v\|^2_H}, \quad v \in V_2.
$$

The Laplace operator with homogeneous Neumann boundary conditions is defined as

$$
-\Delta : V_1 \to V_1^*, \quad \langle -\Delta v, \varphi \rangle_{V_1} := \int_D \nabla v \cdot \nabla \varphi, \quad v, \varphi \in V_1.
$$

We recall that, since $\|\cdot\|_1$ is equivalent to the usual norm in $V_1$, the restriction of $-\Delta$ to $V_{1,0}$ is an isomorphism between $V_{1,0}$ and $V_{1,0}^*$. In particular, it is well defined its inverse

$$
\mathcal{N} : V_{1,0}^* \to V_{1,0},
$$

where for every $v \in V_{1,0}^*$, the element $\mathcal{N}v \in V_{1,0}$ is the unique solution with null mean to the generalized Neumann problem

$$
\int_D \nabla \mathcal{N}v \cdot \nabla \varphi = \langle v, \varphi \rangle_{V_1} \quad \forall \varphi \in V_1, \quad (\mathcal{N}v)_D = 0.
$$

It is clear that $\mathcal{N}$ is an isomorphism between $V_{1,0}^*$ and $V_{1,0}$ satisfying

$$
\langle v_1, \mathcal{N}v_2 \rangle_{V_1} = \langle v_2, \mathcal{N}v_1 \rangle_{V_1} = \int_D \nabla \mathcal{N}v_1 \cdot \nabla \mathcal{N}v_2 \quad \forall v_1, v_2 \in V_{1,0}^*.
$$
Moreover, we also recall that an equivalent norm on $V_1^*$ is given by
$$
\|v\|_* := \sqrt{\|\nabla \mathcal{N}(v - v_D)\|_H^2 + |v_D|^2}, \quad v \in V_1^*,
$$
and that for every $\eta > 0$ there exists $C_\eta > 0$ such that
$$
\|v\|_H^2 \leq \eta \|\nabla v\|_H^2 + C_\eta \|v\|_*^2 \quad \forall v \in V_1.
$$
Finally, for every $v \in H^1(0, T; V_1^*)$ we have
$$
\langle \partial_t v(t), \mathcal{N} v(t) \rangle_{V_1} = \frac{1}{2} \frac{d}{dt} \|\nabla \mathcal{N} v(t)\|_H^2 \quad \text{for a.e. } t \in (0, T).
$$
For any further detail, the reader can refer to [17, pp. 979-980].

For every $\varepsilon \geq 0$, it will be useful to introduce also the space
$$
\bar{V}_{1, \varepsilon} := \begin{cases}
H & \text{if } \varepsilon = 0, \\
V_1 & \text{if } \varepsilon > 0,
\end{cases}
$$
and that for every $\eta > 0$ there exists $C_\eta > 0$ such that
$$
\|v\|_H^2 \leq \eta \|\nabla v\|_H^2 + C_\eta \|v\|_*^2 \quad \forall v \in V_1.
$$
Finally, for every $v \in H^1(0, T; V_1^*)$ we have
$$
\langle \partial_t v(t), \mathcal{N} v(t) \rangle_{V_1} = \frac{1}{2} \frac{d}{dt} \|\nabla \mathcal{N} v(t)\|_H^2 \quad \text{for a.e. } t \in (0, T).
$$
For any further detail, the reader can refer to [17, pp. 979-980].

The following hypotheses will be in order throughout the paper:

(H1) $\beta : \mathbb{R} \to 2^\mathbb{R}$ is a maximal monotone graph, with $0 \in \beta(0)$ and $D(\beta) = \mathbb{R}$. This implies in particular that $\beta$ is the subdifferential of a continuous convex function $\hat{\beta} : \mathbb{R} \to [0, +\infty)$ such that $\hat{\beta}(0) = 0$. We shall also assume a symmetry-like condition on $\hat{\beta}$ of the form
$$
\limsup_{|r| \to +\infty} \frac{\hat{\beta}(r)}{\hat{\beta}(-r)} < +\infty,
$$
which is trivially satisfied if $\hat{\beta}$ is an even function for example. If we denote by $\hat{\beta}^{-1}$ the convex conjugate of $\hat{\beta}$, i.e.
$$
\hat{\beta}^{-1} : \mathbb{R} \to [0, +\infty], \quad \hat{\beta}^{-1}(r) := \sup_{s \in \mathbb{R}} \{sr - \hat{\beta}(s)\}, \quad r \in \mathbb{R},
$$
then it is well-known that $\partial \hat{\beta}^{-1} = \beta^{-1}$, and the fact that $\beta$ is everywhere defined on $\mathbb{R}$ implies that $\hat{\beta}^{-1}$ is superlinear at infinity, i.e.
$$
\lim_{|r| \to +\infty} \frac{\hat{\beta}^{-1}(r)}{r} = +\infty.
$$

(H2) $\pi : \mathbb{R} \to \mathbb{R}$ is a Lipschitz-continuous function such that $\pi(0) = 0$. We shall denote the Lipschitz constant of $\pi$ by $C_\pi$ and we define $\hat{\pi} : \mathbb{R} \to \mathbb{R}$ as $\hat{\pi}(r) := \int_0^r \pi(s) \, ds$.

(H3) $g : \Omega \times [0, T] \to H$ is progressively measurable and $g \in L^2(\Omega \times (0, T); H)$. 
(H4) \( u_0 \in L^2(\Omega, \mathcal{F}_0, \mathbb{P}; H) \), \( \varepsilon u_0 \in L^2(\Omega, \mathcal{F}_0, \mathbb{P}; V_1) \) and \( \hat{\beta}(\alpha(u_0)_D) \in L^1(\Omega) \) for all \( \alpha > 0 \).

Note that the last requirement on \( u_0 \) can be reformulated by saying that the mean of \( u_0 \) on \( D \) must belong to the small Orlicz space generated by \( \hat{\beta} \) on \( \Omega \): the formulation with an arbitrary positive parameter \( \alpha \) is crucial since the potential \( \hat{\beta} \) is allowed to be super-homogeneous as well. Such assumption is not restrictive and is satisfied for example when \( (u_0)_D \) is non-random. If \( \hat{\beta} \) is a polynomial, then the last requirement amounts to saying that \( (u_0)_D \) has finite moment of a certain order.

We are now ready to give the definition of strong solution for the problem. Fix \( \varepsilon > 0 \): recall that we want to study the problem

\[
d(u - \varepsilon \Delta u) - \Delta w \, dt = B(u) \, dW, \quad w \in -\Delta u + \beta(u) + \pi(u) - g,
\]

with homogeneous Neumann conditions on \( u \) and \( w \). In order to understand what a reasonable weak formulation of the problem can be, we argue formally in the first place. Assume that \( (u, \xi) \) is a sufficiently regular solution to our problem: this means that

\[
u - \varepsilon \Delta u - \int_0^t \Delta w(s) \, ds = u_0 - \varepsilon \Delta u_0 + B(\cdot, u) \cdot W, \quad w = -\Delta u + \xi + \pi(u) - g, \quad \xi \in \beta(u).
\]

A weak formulation of the problem can be obtained by multiplying by a suitable test function \( \varphi \) and integrating by parts on \( D \). In particular, taking into account the boundary conditions of \( u \) and \( w \), we see that if \( \partial_n \varphi = 0 \), then

\[
\int_D u \varphi + \varepsilon \int_D \nabla u \cdot \nabla \varphi - \int_0^t \int_D w(s) \Delta \varphi \, ds = \int_D u_0 \varphi + \varepsilon \int_D \nabla u_0 \cdot \nabla \varphi + \int_D (B \cdot W) \varphi.
\]

Due to the singularity of \( \beta \), we cannot expect \( \xi \) (hence also \( w \)) to be \( H \)-valued, but only \( L^1(D) \)-valued. Consequently, the choice of the space of test functions should also guarantee at least that \( \Delta \varphi \in L^\infty(D) \). For example, we can take \( \varphi \in V_4 \), which ensures both that \( \partial_n \varphi = 0 \) and, thanks to the Sobolev embeddings, that \( \Delta \varphi \in H^2(D) \hookrightarrow L^\infty(D) \).

Let us now state the definition of strong solution for the problem in a rigorous way.

**Definition 2.1** (Strong solution). Let \( \varepsilon \geq 0 \). A strong solution to \((1.1) - (1.4)\) is a triplet \((u, w, \xi)\), where \( u \) is an \( H \)-valued process, \( w \) is a \( L^1(D) \)-valued adapted process and \( \xi \) is a \( L^1(D) \)-valued predictable process, such that

\[
u \in L^2(\Omega; C^0([0, T]; V_1^*)) \cap L^2(\Omega; L^\infty(0, T; H)) \cap L^2(\Omega; L^2(0, T; V_2)), \quad \varepsilon u \in L^2(\Omega; C^0([0, T]; H)) \cap L^2(\Omega; L^\infty(0, T; V_1)), \quad w, \xi \in L^1(\Omega \times (0, T) \times D),
\]

\[
\hat{\beta}(u) + \hat{\beta}^{-1}(\xi) \in L^1(\Omega \times (0, T) \times D), \quad \xi \in \beta(u) \quad \text{a.e. in } \Omega \times (0, T) \times D,
\]

\[
w = -\Delta u + \xi + \pi(u) - g
\]

and, for every \( t \in [0, T] \), \( \mathbb{P} \)-almost surely,

\[
\int_D u(t) \varphi + \varepsilon \int_D \nabla u(t) \cdot \nabla \varphi - \int_0^t \int_D w(s) \Delta \varphi \, ds = \int_D u_0 \varphi + \varepsilon \int_D \nabla u_0 \cdot \nabla \varphi + \left\langle \int_0^t B(s, u(s)) \, dW(s), \varphi \right\rangle_{V_1}, \quad \forall \varphi \in V_4.
\]
We collect now the main results of the paper. The first two results deal with the well-posedness of the problem in the case of additive and multiplicative noise. We prefer to separate the two cases since with additive noise the stochastic integral is allowed to be more general, while with multiplicative noise it is forced to take values in the space of mean-null elements (see also Remark 2.3). The pure and viscous cases are analyzed simultaneously by considering $\varepsilon \geq 0$.

**Theorem 2.2** (Well-posedness, additive noise). Let $\varepsilon \geq 0$, $(u_0, g)$ satisfy (H1)–(H4) and

$$B \in L^2(\Omega \times (0, T); \mathcal{L}^2(U, V_{1,\varepsilon})) \text{ progressively measurable},$$

$$\tilde{\beta}(\alpha(B \cdot W)_D) \in L^1(\Omega \times (0, T)) \quad \forall \alpha > 0.$$  \hspace{1cm} (2.1)

Then the problem (1.1)–(1.3) admits a strong solution. Furthermore, for every $p \in [1, 2]$ there exists a constant $K > 0$, independent of $\varepsilon$, such that if $(u_1, g_1, B_1)$ and $(u_0, g_2, B_2)$ satisfy (H1)–(H4), (2.1)–(2.2) and

$$(u_0)_D + (B_1 \cdot W)_D = (u_0^2)_D + (B_2 \cdot W)_D,$$  \hspace{1cm} (2.3)

then, for any respective strong solutions $(u_1, w_1, \xi_1)$ and $(u_2, w_2, \xi_2)$ to (1.1)–(1.3),

$$\|u_1 - u_2\|_{L^p(\Omega; C^{0,\alpha}(0, T); V_{1,\varepsilon}^*)} + \varepsilon^{p/2} \|u_1 - u_2\|_{L^p(\Omega; C^{0,\alpha}(0, T); H)} + \|\nabla(u_1 - u_2)\|_{L^p(\Omega; L^2(0, T; H))} \leq K \left(\|u_0 - u_0^2\|_{L^p(\Omega; V_{1,\varepsilon}^*)} + \|g_1 - g_2\|_{L^p(\Omega; L^2(0, T; V_{1,\varepsilon}^*))} + \|B_1 - B_2\|_{L^p(\Omega; L^2(0, T; \mathcal{L}^2(U, V_{1,\varepsilon}^*))}\right).$$

In particular, (2.3) is true if $B_1$ and $B_2$ take values in $\mathcal{L}^2(U, V_{1,0}^*)$ and $(u_0)_D = (u_0^2)_D$.

**Remark 2.3.** Note that the assumptions (2.1)–(2.2) allow the operator $B$ to take values in the larger space $\mathcal{L}^2(U, V_{1,\varepsilon}^*)$, which has to be interpreted as $\mathcal{L}^2(U, H)$ if $\varepsilon = 0$ and $\mathcal{L}^2(U, V_1^*)$ if $\varepsilon > 0$. This is a generalization with respect to the classical results dealing with the stochastic Cahn-Hilliard equation, which usually require that $B$ takes values in $\mathcal{L}^2(U, H_0)$ instead: see for example [24][61]. This is usually done in order to ensure the conservation of the mean of $u$ in the system: in this work, we show however that in case of additive noise this is not necessary, provided that a suitable control on the $\tilde{\beta}$-moment of $(B \cdot W)_D$ holds. Of course, if $B$ is $\mathcal{L}^2(U, V_{1,\varepsilon}^* \cap V_{1,0}^*)$-valued, hypothesis (2.2) is clearly satisfied. Furthermore, note that if $\tilde{\beta}$ is controlled by a polynomial of order $p$, then by homogeneity it is not restrictive to consider only the case $\alpha = 1$, and it is readily seen that (2.2) is true if

$$\|B \cdot W\|_{C^{0,\alpha}(0, T); V_{1,\varepsilon}^*} \in L^p(\Omega),$$

which can be easily checked in turn through the Jensen and Burkholder-Davis-Gundy inequalities for example.

**Theorem 2.4** (Well-posedness, multiplicative noise). Let $\varepsilon \geq 0$ and $(u_0, g)$ satisfy (H1)–(H4). Let also $B : \Omega \times [0, T] \times V_1 \rightarrow \mathcal{L}^2(U, V_{1,\varepsilon}^* \cap V_{1,0}^*)$ be progressively measurable, and assume that there exists a constant $N_B > 0$ and an adapted process $f \in L^1(\Omega \times (0, T))$ such that, for every $(\omega, t) \in \Omega \times [0, T],

$$\|B(\omega, t, v_1) - B(\omega, t, v_2)\|_{\mathcal{L}^2(U, V_{1,\varepsilon}^*)} \leq N_B \|u - v\|_{V_{1,\varepsilon}^*}^2 \quad \forall v_1, v_2 \in V_2,$$  \hspace{1cm} (2.4)

$$\|B(\omega, t, v)\|_{\mathcal{L}^2(U, V_{1,\varepsilon}^*)} \leq f(\omega, t) + N_B \|v\|_{V_{1,\varepsilon}^*}^2 \quad \forall v \in V_1.$$  \hspace{1cm} (2.5)
Then the problem \((1.1) - (1.4)\) admits a strong solution. Furthermore, for every \(p \in [1, 2]\) there exists a constant \(K > 0\), independent of \(\varepsilon\), such that if \((u_0^1, g_1)\) and \((u_0^2, g_2)\) satisfy \((H1) - (H4)\) and

\[
(u_0^1)_D = (u_0^2)_D, \quad (2.6)
\]
then, for any respective strong solutions \((u_1, w_1, \xi_1)\) and \((u_2, w_2, \xi_2)\) to \((1.1) - (1.4)\),

\[
\|u_1 - u_2\|_{L^p(\Omega; C^0([0,T]; V^*_1))} + \varepsilon^{p/2} \|u_1 - u_2\|_{L^p(\Omega; C^0([0,T]; H))} + \|\nabla (u_1 - u_2)\|_{L^p(\Omega; L^2(0,T; H))} \\
\leq K \left( \|u_0^1 - u_0^2\|_{L^p(\Omega; V^*_1)} + g_1 - g_2\right)_{L^p(\Omega; L^2(0,T; V^*_1))}.
\]

**Remark 2.5.** Let us mention that the well-posedness result implies that the solution map associating the data \((u_0, g)\) to the (unique) solution component \(u\) can be extended to the spaces

\[
L^2(\Omega; V^*_1) \times L^2(\Omega \times (0,T); V^*_1) \to L^2(\Omega; C^0([0,T]; V^*_1)) \cap L^2(\Omega \times (0,T); V_1),
\]
so that one could possibly define an even weaker concept of solution by performing classical density arguments. This basically corresponds to considering the evolution system exclusively on the dual space \(V^*_1\), with no further regularity a priori.

The next two results concern the vanishing viscosity limit of the problem as \(\varepsilon \searrow 0\), in the case of both additive and multiplicative noise. In particular, we prove that any strong solution to the viscous problem converges in suitable topologies to a strong solution of the pure equation as the viscosity coefficient \(\varepsilon\) goes to 0.

**Theorem 2.6 (Asymptotics as \(\varepsilon \searrow 0\), additive noise).** Assume \((H1) - (H3)\), and let \(u_0 \in L^2(\Omega, \mathcal{F}_0, \mathbb{P}; H)\) and \(B \in L^2(\Omega \times (0,T); \mathcal{L}^2(U, H))\) be progressively measurable. Suppose also that

\[
(u_0^\varepsilon)_{\varepsilon > 0} \subset L^2(\Omega, \mathcal{F}_0, \mathbb{P}; V_1), \quad (g^\varepsilon)_{\varepsilon} \subset L^2(\Omega \times (0,T); H),
\]

\[
(B^\varepsilon)_{\varepsilon > 0} \subset L^2(\Omega \times (0,T); \mathcal{L}^2(U, H)) \quad \text{progressively measurable}
\]
are such that

\[
u_0^\varepsilon \to u_0 \quad \text{in} \quad L^2(\Omega; H), \quad (\varepsilon^{1/2} u_0^\varepsilon)_{\varepsilon > 0} \quad \text{is bounded in} \quad L^2(\Omega; V_1), \quad (2.7)
\]

\[
g^\varepsilon \to g \quad \text{in} \quad L^2(\Omega \times (0,T); H), \quad (2.8)
\]

\[
B^\varepsilon \to B \quad \text{in} \quad L^2(\Omega \times (0,T); \mathcal{L}^2(U, H)), \quad (2.9)
\]

\[
(u_0^\varepsilon)_D + (B^\varepsilon \cdot W)_D = (u_0)_D + (B \cdot W)_D \quad \forall \varepsilon > 0. \quad (2.10)
\]

For any \(\varepsilon > 0\), let \((u^\varepsilon, w^\varepsilon, \xi^\varepsilon)\) be any strong solutions to problem \((1.1) - (1.4)\) with data \((u_0^\varepsilon, g^\varepsilon, B^\varepsilon)\). Then there exists a strong solution \((u, w, \xi)\) to \((1.1) - (1.4)\) with data \((u_0, g, B)\) in the case \(\varepsilon = 0\) such that, as \(\varepsilon \searrow 0\):

\[
u^\varepsilon \to u \quad \text{in} \quad L^p(\Omega; L^2(0,T; V_1)) \quad \forall p \in [1, 2), \quad (2.11)
\]

\[
u^\varepsilon \to u \quad \text{in} \quad L^2(\Omega; L^2(0,T; V_2)) \quad \text{with} \quad \varepsilon u^\varepsilon \to 0 \quad \text{in} \quad L^\infty(0,T; L^2(\Omega; H)), \quad (2.12)
\]

\[
wp^\varepsilon \to w \quad \text{in} \quad L^1(\Omega \times (0,T) \times D), \quad \xi^\varepsilon \to \xi \quad \text{in} \quad L^1(\Omega \times (0,T) \times D). \quad (2.13)
\]
**Theorem 2.7** (Asymptotics as \( \varepsilon \nearrow 0 \), multiplicative noise). Assume \((H1)-(H3)\) and let 
\( u_0 \in L^2(\Omega, \mathcal{F}_0, \mathbb{P}; H) \) and \( B : \Omega \times [0, T] \times V_1 \rightarrow \mathcal{L}^2(U, H_0) \) progressively measurable satisfying \((2.1) - (2.3)\) (with the choice \( \varepsilon = 0 \)). Let also \((u_0, g) \) and \((g_\varepsilon) \) satisfy conditions \((2.7) - (2.8)\) and

\[
(u_0)_D = (u_0)_D \quad \forall \varepsilon > 0.
\]

For any \( \varepsilon > 0 \), let \((u_\varepsilon, w_\varepsilon, \xi_\varepsilon)\) be any strong solutions to problem \((1.1) - (1.4)\) with multiplicative noise \( B \) and data \((u_0, g)\). Then there exists a strong solution \((u, w, \xi)\) to \((1.1) - (1.4)\) with multiplicative noise \( B \) and data \((u_0, g)\) in the case \( \varepsilon = 0 \) such that, as \( \varepsilon \nearrow 0 \), the convergences of Theorem 2.6 hold.

**Remark 2.8.** Let us comment on the compatibility assumptions \((2.10)\) and \((2.11)\), which require the approximating families \((u_0, g)\) and \((B_\varepsilon)\) to preserve the mean. Note that this is trivially satisfied for example in the classical case of elliptic-type approximations of the data: for instance, the choices \( u_0 := (I - \varepsilon \Delta)^{-1} u_0 \) and \( B_\varepsilon := (I - \varepsilon \Delta)^{-1} B \) easily fulfil the assumptions above.

The last results of this paper concern the regularity of the system. In the first regularity result that we present, we show how additional requirements on the moments of the data \((u_0, g, B)\) improve the corresponding regularity of the solutions in the classical case of a polynomial double-well potential of degree 4. This yields, in the viscous case, some \( L^2 \)-estimates (in space and time) on \( w \) and on \( \xi \).

**Theorem 2.9** (Regularity 1). Let \( \varepsilon \geq 0 \), \( p \geq 2 \). Assume \((H1)-(H4)\), \((2.1) - (2.2)\) and

\[
\begin{align*}
  u_0 &\in L^p(\Omega; H), \quad \varepsilon u_0 \in L^p(\Omega; V_1), \\
  g &\in L^p(\Omega; L^2(0, T; H)), \quad B \in L^p(\Omega; L^2(0, T; \mathcal{L}^2(U, V_{1,\varepsilon}))), \\
  \end{align*}
\]

Then the unique strong solution \((u, w, \xi)\) to \((1.1) - (1.4)\) also satisfies

\[
\begin{align*}
  u &\in L^p(\Omega; L^\infty(0, T; H)) \cap L^p(\Omega; L^2(0, T; V_2)), \\
  \varepsilon u &\in L^p(\Omega; L^\infty(0, T; V_1)).
\end{align*}
\]

Furthermore, if also

\[
\beta : \mathbb{R} \rightarrow \mathbb{R} \text{ is single-valued}, \quad \exists R > 0 : \quad |\beta(x)| \leq R \left( 1 + |x|^3 \right) \quad \forall x \in \mathbb{R},
\]

then

\[
\varepsilon w \in L^{p/3}(\Omega; L^2(0, T; H)), \quad \varepsilon \xi \in L^{p/3}(\Omega; L^2(0, T; H));
\]

if also

\[
\beta \in W^{1,\infty}_{\text{loc}}(\mathbb{R}), \quad \exists R > 0 : \quad \beta'(x) \leq R \left( 1 + |x|^2 \right) \text{ for a.e. } x \in \mathbb{R},
\]

then

\[
\varepsilon \xi \in L^{p/3}(\Omega; L^2(0, T; V_1)).
\]

We are now ready to present the second regularity result. Note that in the Definition 2.1 of strong solution the component \( w \) of the chemical potential is only \( L^1 \) globally. However, this forces to have a variational formulation of the problem where all the spatial derivatives are shifted on the test function, whereas the most natural and classical formulation in the context of Cahn-Hilliard equations involves the gradient of the chemical
potential \( w \). Such a formulation is much more natural and effective both in terms of applications and from a mathematical point of view: indeed, it provides better estimates on the solutions, which are used in turn in a wide variety of concrete situations, such as, among all, optimal control problems. The possibility of writing a more natural variational formulation of the system, hence to give sense in a suitable way to \( \nabla w \), is strictly connected to the possibility of writing a \( \text{Itô-type} \) formula, or, better said, inequality, to the so-called free-energy functional of the system, defined as

\[
\mathcal{E}(u) := \frac{1}{2} \int_D |\nabla u|^2 + \int_D \hat{\beta}(u) + \int_D \hat{\pi}(u).
\]

In order to achieve so, further assumptions on the data are needed. We collect such a regularity result here.

**Theorem 2.10** (Regularity II). Let \( \varepsilon \geq 0, \ q \geq 2 \). Assume (H1)–(H4), (2.1)–(2.2) and

\[
\beta : \mathbb{R} \to \mathbb{R} \quad \text{is single-valued,} \quad \beta \in W^{1,\infty}_{\text{loc}}(\mathbb{R}),
\]

\[
\exists R > 0 : \quad \beta(x) \leq R \left( 1 + \hat{\beta}(x) \right) \quad \forall x \in \mathbb{R},
\]

\[
g \in L^q(\Omega; L^2(0, T; V_1)),
\]

\[
u_0 \in L^q(\Omega, \mathcal{F}_0, \mathbb{P}; V_1), \quad \hat{\beta}(u_0) \in L^q(\Omega, \mathcal{F}_0, \mathbb{P}; L^1(D)),
\]

\[
(I - \varepsilon \Delta)^{-1} B \in L^q(\Omega; L^2(0, T; L^2(U, V_1))), \quad B \in L^q(\Omega; L^\infty(0, T; L^2(U, V^*_1))).
\]

Assume also one condition between (2.19)–(2.20) and one between (2.21)–(2.22), where

\[
B \in L^\infty(\Omega \times (0, T); L^2(U, V^*_1)),
\]

\[
B \in L^q(\Omega; L^\infty(0, T; L^2(U, V^*_{1, 0}))),
\]

and

\[
\begin{align*}
\exists R > 0 : \quad & \beta'(x) \leq R \left( 1 + |x|^2 \right) \quad \text{for a.e. } x \in \mathbb{R}, \\
(I - \varepsilon \Delta)^{-1} B \in L^\infty(\Omega \times (0, T); L^2(U, H)) + L^q(0, T; L^{\infty}(\Omega; L^2(U, V^*_{1, 0}))),
\end{align*}
\]

\[
\begin{cases}
\exists R > 0 : \quad & \beta'(x) \leq R \left( 1 + \hat{\beta}(x) \right) \quad \text{for a.e. } x \in \mathbb{R}, \\
\exists s > \frac{N}{2} : \quad & (I - \varepsilon \Delta)^{-1} B \in L^q(0, T; L^\infty(\Omega; L_2(U, V_s))).
\end{cases}
\]

Then the unique strong solution \((u, w, \xi)\) to (1.1)–(1.4) satisfies

\[
u \in L^q(\Omega; C^0([0, T]; H)) \cap L^q(\Omega; L^\infty(0, T; V_1)) \cap L^q(\Omega; L^2(0, T; V_2)),
\]

\[
w \in L^q(\Omega; L^2(0, T; V_1)), \quad \xi \in L^{q/2}(\Omega; L^2(0, T; H)) \cap L^{q/2}(\Omega; L^\infty(0, T; L^1(D))),
\]

\[
\hat{\beta}(u) \in L^{q/2}(\Omega; L^\infty(0, T; L^1(D))), \quad \hat{\beta}^{-1}(\xi) \in L^1(\Omega \times (0, T) \times D),
\]

and the following variational formulation of (1.1)–(1.4) holds:

\[
\int_D u(t) \varphi + \varepsilon \int_D \nabla u(t) \cdot \nabla \varphi + \int_{Q_1} \nabla w(t) \cdot \nabla \varphi = \int_D u_0 \varphi + \varepsilon \int_D \nabla u_0 \cdot \nabla \varphi + \int_D \left( \int_0^t B(s) \, dW(s) \right) \varphi \quad \forall \varphi \in V_1,
\]

\[
\int_D w(t) \varphi = \int_D \nabla u(t) \cdot \nabla \varphi + \int_D \xi(t) \varphi + \int_D \pi(u(t)) \varphi - \int_D g(t) \varphi \quad \forall \varphi \in V_1,
\]

\[
\int_D \pi(t) \varphi = \int_D \pi(t) \varphi - \int_D \pi(t) \varphi \quad \forall \varphi \in V_1.
\]
for every \( t \in [0, T] \) and almost every \( t \in (0, T) \), respectively, \( \mathbb{P} \)-almost surely. Furthermore if (2.21) is in order, it also holds that
\[
    u \in L^{q/3}(\Omega; L^2(0, T; V_3)), \quad \xi \in L^{q/2,q/3}(\Omega; L^2(0, T; V_1)).
\]

**Remark 2.11.** Let us stress that the regularity result obtained here allows to give a natural variational formulation to the problem which is more usable in practice in the context of Cahn-Hilliard-related problem (for example, optimal control problems). The variety of assumptions provided on \( \beta \) and \( B \) allow also to obtain such regularity properties also in the degenerate cases where \( B \) has not null-mean and \( \beta \) is not necessarily a polynomial function. We point out that the hypotheses on the operator \( B \) are satisfied, for example, when \( B \) is independent of \( \omega \) and \( t \), and takes values in the smoother spaces of the form \( \mathcal{L}^2(U, V_s) \) for a suitable \( s \). More specifically, the choice between (2.19)–(2.20) is motivated by the wish of giving an appropriate regularity result also in the more difficult case where \( B \) is not necessarily of null mean. On the other side, in (2.21)–(2.22) we are distinguishing between the possibly different growth of \( \beta \): the first case is the classical one corresponding to a polynomial double-well potential of degree 4, while in the second we only require \( \beta' \) to be controlled by \( \hat{\beta} \), allowing thus also first-order exponential growth for example.

Finally, the combination of Theorems 2.9, 2.10 yields as a direct consequence some refined regularity results for the solutions.

**Corollary 2.12** (Further regularity). Let \( \varepsilon \geq 0 \) and \( p, q \geq 2 \). Assume the hypotheses (H1)–(H4), (2.1)–(2.2), (2.13)–(2.18), (2.21), (2.12)–(2.13) and one condition between (2.19)–(2.20). Then the unique strong solution \( (u, w, \xi) \) to (1.1)–(1.4) satisfies
\[
    u \in L^{p,q}(\Omega; C^0([0, T]; H) \cap L^2(0, T; V_2)) \cap L^q(\Omega; L^\infty(0, T; V_1)) \cap L^{q/3}(\Omega; L^2(0, T; V_3)),
\]
\[
    u \in L^p(\Omega; L^\infty(0, T; V_1)) \cap L^{p/3,q/(3)}(\Omega; L^2(0, T; V_3)),
\]
\[
    w \in L^{q/2,q}(\Omega; L^2(0, T; V_1)), \quad \varepsilon w \in L^{p/(q/2),q}(\Omega; L^2(0, T; V_1)),
\]
\[
    \xi \in L^{q/2,q/3}(\Omega; L^2(0, T; V_1)) \cap L^{q/2}(\Omega; L^\infty(0, T; L^1(D))), \quad \varepsilon \xi \in L^{p/3}(\Omega; L^2(0, T; V_1)),
\]
\[
    \hat{\beta}(u) \in L^{q/2}(\Omega; L^{\infty}(0, T; L^1(D))), \quad \bar{\beta}^{-1}(\xi) \in L^1(\Omega \times (0, T) \times D).
\]

## 3 Well-posedness

This section is devoted to the proof of well-posedness in the viscous case \( \varepsilon > 0 \) (the pure case \( \varepsilon = 0 \) has been studied in [61]).

We shall consider first the additive noise case, i.e. when \( B \) is a \( \mathcal{L}^2(U, V_s^*) \)-valued progressively measurable process such that
\[
    B \in L^2(\Omega \times (0, T); \mathcal{L}^2(U, V_s^*)).
\]

The idea to prove existence of solutions is to use a double approximation on the data of the problem: the first one consists is smoothing the coefficient \( B \) is a suitable way, and the second is the natural Yosida approximation on the nonlinearity. In order to avoid
heavy notations, we proceed in the following way: we assume a further regularity on \( B \) is a first step, namely that
\[
B \in L^2(\Omega \times (0, T); \mathcal{L}^2(U, V_4))
\] (3.1)
and we prove well-posedness regularizing the nonlinearity \( \beta \) through its Yosida approximation. Finally, we remove the additional assumption (3.1) using a second approximation of elliptic type on the noise.

The generalization to multiplicative noise is carried out at the end of the section.

Let us work now under the additional assumption (3.1) and \( \varepsilon > 0 \) fixed.

### 3.1 The approximation

For any positive \( \lambda \), we denote by \( \beta_\lambda : \mathbb{R} \to \mathbb{R} \) and \( \hat{\beta}_\lambda : \mathbb{R} \to [0, +\infty) \) the Yosida approximation of \( \beta \) and the Moreau-Yosida regularization of \( \hat{\beta} \), respectively. The approximated problem is the following:

\[
d(u_\lambda - \varepsilon \Delta u_\lambda)(t) - \Delta w_\lambda(t) dt = B(t) dW(t)
\]
in \((0, T) \times D\),
\[
w_\lambda = - \Delta u_\lambda + \beta_\lambda(u_\lambda) + \pi(u_\lambda) - g
\]
in \((0, T) \times D\),
\[
\partial_n u_\lambda = 0, \quad \partial_n w_\lambda = 0
\]
in \((0, T) \times \partial D\),
\[
u_\lambda(0) = u_0
\]
in \(D\).

Bearing in mind Definition 2.1, a strong solution to the approximated problem is a couple \((u_\lambda, w_\lambda)\), where \( u_\lambda \) is a \( V_1 \)-valued adapted process, \( w_\lambda \) is an \( H \)-valued adapted process, such that
\[
\begin{align*}
u_\lambda & \in L^2(\Omega; C^0([0, T]; V_1)) \cap L^2(\Omega; L^2(0, T; V_2)), \\
w_\lambda & = - \Delta u_\lambda + \beta_\lambda(u_\lambda) + \pi(u_\lambda) - g \in L^2(\Omega; L^2(0, T; H))
\end{align*}
\]
and satisfying, for every \( t \in [0, T] \), \( \mathbb{P} \)-almost surely,

\[
\int_D u_\lambda(t) \varphi + \varepsilon \int_D \nabla u_\lambda(t) \cdot \nabla \varphi - \int_0^t \int_D w_\lambda(s) \Delta \varphi ds = \int_D u_0 \varphi + \varepsilon \int_D \nabla u_0 \cdot \nabla \varphi + \int_D \left( \int_0^t B(s, u(s)) dW(s) \right) \varphi \quad \forall \varphi \in V_2.
\]

First of all, since the bilinear form
\[
(v_1, v_2)_{1, \varepsilon} := V_1^* \langle v_1 - \varepsilon \Delta v_1, v_2 \rangle_{V_1} = \int_D v_1 v_2 + \varepsilon \int_D \nabla v_1 \cdot \nabla v_2,
\]
defines an equivalent scalar product on \( V_1 \), it is natural to identify the Hilbert space \( V_1 \) with its dual \( V_1^* \) through the isomorphism \( I - \varepsilon \Delta \). Secondly, since \( V_2 \hookrightarrow V_1 \) continuously and densely, then \( V_1^* \) is canonically embedded in \( V_2^* \) through the dualization given by \( I - \varepsilon \Delta \), namely
\[
V_2 \hookrightarrow V_1 \xrightarrow{I-\varepsilon \Delta} V_1^* \hookrightarrow V_2^*.
\]
where all inclusions are continuous and dense. This means that every \( v \in V_1 \) belongs also to \( V_2^* \) and the duality is given by
\[
v_2^* \langle v, \varphi \rangle_{V_2} = (v, \varphi)_{1,\varepsilon} \quad \forall \varphi \in V_2.
\]

Working on the Hilbert triplet \((V_2, V_1, V_2^*)\) with this given dualization of \(V_1\), we define the operator \(\mathcal{A}_\lambda : \Omega \times [0, T] \times V_2 \to V_2^*\) as
\[
v_2^* \langle \mathcal{A}_\lambda(\omega, t, v), \varphi \rangle_{V_2} := \int_D \Delta v \Delta \varphi - \int_D \beta_\lambda(v) \Delta \varphi - \int_D \pi(v) \Delta \varphi + \int_D g(\omega, t) \Delta \varphi,
\]
\((\omega, t) \in \Omega \times [0, T], \ v, \varphi \in V_2\).

With this notation, bearing in mind the definition of \((\cdot, \cdot)_{1,\varepsilon}\), the variational formulation of the approximated problem in the triplet \((V_2, V_1, V_2^*)\) is given by
\[
(u_\lambda(t), \varphi)_{1,\varepsilon} + \int_0^t v_2^* \langle \mathcal{A}_\lambda(s, u_\lambda(s)), \varphi \rangle_{V_2} \ ds = (u_0, \varphi)_{1,\varepsilon} + \left( \int_0^t (I - \varepsilon \Delta)^{-1} B(s) \ dW(s), \varphi \right)_{1,\varepsilon}
\]
for every \( \varphi \in V_2 \). Hence, in order to study existence and uniqueness of an approximated solution \(u_\lambda\), it is enough to check that the operator \(\mathcal{A}_\lambda\) satisfies the usual hypotheses of hemicontinuity, (weak) monotonicity, coercivity and boundedness of the classical variational theory in the triplet \((V_2, V_1, V_2^*)\) (see [45,57,58]).

**Remark 3.1.** Let us comment on the definition of the operator \(\mathcal{A}_\lambda\). In particular, we want to stress that \(\mathcal{A}_\lambda\) is not the weak realization of the operator \(-\Delta(-\Delta + \beta_\lambda + \pi - g)\). This is because we are not identifying \(H\) with \(H^*\) in the classical way, but the dualization is given on the “pivot” space \(V_1\) by the isomorphism \(I - \varepsilon \Delta\). In a formal way, but perhaps more explicative, we are applying the operator \((I - \varepsilon \Delta)^{-1}\) to the approximated equation \([3,2]\), in order to shift the evolution from \(V_1^*\) to \(V_1\): this explains why the stochastic integrand on the right-hand side is \((I - \varepsilon \Delta)^{-1} B\). Taking this remark into account, the operator \(\mathcal{A}_\lambda\) is the weak formulation of the (random and time-dependent) unbounded operator \(\mathcal{A}_\lambda\) on \(V_1\) defined as
\[
\mathcal{A}_\lambda(\omega, t, v) := -\Delta(I - \varepsilon \Delta)^{-1}(-\Delta v + \beta_\lambda(v) + \pi(v) - g(\omega, t)), \quad (\omega, t) \in \Omega \times [0, T],
\]
\(v \in D(\mathcal{A}_\lambda(\omega, t, \cdot)) := \{v \in V_1 : -\Delta v + \beta_\lambda(v) + \pi(v) - g(\omega, t) \in V_1\}\).

This can be checked also explicite in a direct way. Indeed, for every \((\omega, t) \in \Omega \times [0, T], v \in D(\mathcal{A}_\lambda(\omega, t, \cdot))\) and \(\varphi \in V_2\), we have \(\mathcal{A}_\lambda(\omega, t, v) \in V_1\): hence, recalling that \(V_1 \hookrightarrow V_2^*\) through the dualization given by \(I - \varepsilon \Delta\),
\[
v_2^* \langle \mathcal{A}_\lambda(\omega, t, v), \varphi \rangle_{V_2} = (\mathcal{A}_\lambda(\omega, t, v), \varphi)_{1,\varepsilon} = v_1^* \langle (I - \varepsilon \Delta) \mathcal{A}_\lambda(\omega, t, v), \varphi \rangle_{V_1}
\]
\(= v_1^* \langle -\Delta(-\Delta v + \beta_\lambda(v) + \pi(v) - g(\omega, t)), \varphi \rangle_{V_1}
\]
\(= -\int_D (-\Delta v + \beta_\lambda(v) + \pi(v) - g(\omega, t)) \Delta \varphi = v_2^* \langle \mathcal{A}_\lambda(\omega, t, v), \varphi \rangle_{V_2} \).

Hence, \(\mathcal{A}_\lambda\) extends continuously to the weak operator \(\mathcal{A}_\lambda\).

**Lemma 3.2.** For every \(\lambda > 0\), the operator \(\mathcal{A}_\lambda : \Omega \times [0, T] \times V_2 \to V_2^*\) is progressively measurable and satisfies the following conditions:
• **hemicontinuity**: the map \( r \mapsto v_2^*(A_\lambda(\omega, t, v_1 + rv_2), \varphi) \), \( r \in \mathbb{R} \), is continuous for every \((\omega, t) \in \Omega \times [0, T] \) and \( v_1, v_2, \varphi \in V_2 \);

• **weak monotonicity**: there exists \( c > 0 \) such that, for every \((\omega, t) \in \Omega \times [0, T] \),
\[
v_2^*(A_\lambda(\omega, t, v_1) - A_\lambda(\omega, t, v_2), v_1 - v_2) \geq -c\|v_1 - v_2\|^2_{V_1} \quad \forall v_1, v_2 \in V_2;
\]

• **weak coercivity**: there exist \( c_1, c'_1 > 0 \) and an adapted process \( f_1 \in L^1(\Omega \times (0, T)) \) such that, for every \((\omega, t) \in \Omega \times [0, T] \),
\[
v_2^*(A_\lambda(\omega, t), v) \geq c_1\|v\|^2_{V_1} - c'_1\|v\|^2_{V_1} - f_1(\omega, t) \quad \forall v \in V_2;
\]

• **weak boundedness**: there exists \( c_2 > 0 \) and an adapted process \( f_2 \in L^1(\Omega \times (0, T)) \) such that, for every \((\omega, t) \in \Omega \times [0, T] \),
\[
\|A_\lambda(\omega, t)\|^2_{V_2^*} \leq c_2\|v\|^2_{V_1} + f_2(\omega, t) \quad \forall v \in V_2.
\]

**Proof.** We refer to [61, Lemma 3.1]: the proof is based on the fact that \( V_1 \hookrightarrow H \) and the Lipschitz continuity of \( \beta_\lambda \) and \( \pi \).

Owing to the last lemma, we can infer that there exists a unique adapted process
\[
\lambda \in L^2(\Omega; C^0([0, T]; V_1)) \cap L^2(\Omega; L^2(0, T; V_2))
\]
such that
\[
u_\lambda(t) + \int_0^t A_\lambda(s, u_\lambda(s)) \, ds = u_0 + \int_0^t (I - \varepsilon \Delta)^{-1}B(s) \, dW_s \quad \forall t \in [0, T], \quad \mathbb{P}\text{-a.s.,}
\]
where the equality is intended in the Hilbert triplet \((V_2, V_1, V_2^*)\) with the dualization given by \( I - \varepsilon \Delta \). In other words, setting
\[
w_\lambda := -\Delta u_\lambda + \beta_\lambda(u_\lambda) + \pi(u_\lambda) - g \in L^2(\Omega; L^2(0, T; H)),
\]
we have, for every \( t \in [0, T] \), \( \mathbb{P}\)-almost surely,
\[
(u_\lambda(t), \varphi)_{1, \varepsilon} - \int_0^t \int_D w_\lambda(s) \Delta \varphi \, ds = (u_0, \varphi)_{1, \varepsilon} + \left\langle \int_0^t B(s) \, dW(s), \varphi \right\rangle_{V_1} \quad \forall \varphi \in V_2.
\]

**3.2 Pathwise estimates**

In this section we prove pathwise estimates on the approximated solutions, independently of the parameter \( \lambda \). The term “pathwise” refers here to the fact that \( \omega \) is fixed in a suitable set of probability 1 in \( \Omega \). To this end, we can rewrite the approximated equation as
\[
\partial_t(u_\lambda - (I - \varepsilon \Delta)^{-1}B \cdot W) + A_\lambda(\cdot, u_\lambda) = 0 \quad \text{in } V_2^*, \quad \text{a.e. in } (0, T), \quad \mathbb{P}\text{-a.s.} \quad (3.6)
\]
First of all, testing \((3.6)\) by \( \varphi = \frac{1}{|D|} \), since the operator \((I - \varepsilon \Delta)^{-1}\) preserves the mean we infer that
\[
u_\lambda(t)_D = m(t) := (u_0)_D + (B \cdot W(t))_D \quad \forall t \in [0, T],
\]
where \( m \in L^2(\Omega; C^0([0,T])) \) thanks to the properties of the stochastic integral. Similarly,
\[
(u_\lambda - (I - \varepsilon \Delta)^{-1}B \cdot W)_D = (u_\lambda - B \cdot W)_D = (u_0)_D,
\]
so that we can define \( m_\varepsilon := (u_0)_D + (I - \varepsilon \Delta)^{-1}B \cdot W \in L^2(\Omega; C^0([0,T]; V_1)) \). Taking these remarks into account, thanks to the assumptions \((H5)\) and \((3.1)\) on \( u_0 \) and \( B \), respectively, there is \( \Omega' \in \mathcal{F} \) (independent of both \( \lambda \) and \( \varepsilon \)) with \( \mathbb{P}(\Omega') = 1 \) such that, for every \( \omega \in \Omega' \),
\[
u_0(\omega) \in V_1, \quad \hat{\beta}(\alpha u_0(\omega)) < +\infty \quad \forall \alpha > 0, \quad B \cdot W(\omega) \in C^0([0,T]; V_1) \hookrightarrow L^\infty(Q), \quad m(\omega) \in C^0([0,T]), \quad m_\varepsilon(\omega) \in C^0([0,T]; V_1).
\]

Let us fix now \( \omega \in \Omega' \): in the sequel, we do not write the dependence on \( \omega \) explicitly.

We shall need the following lemma.

**Lemma 3.3.** The map
\[
\phi : V_1 \to V_1, \quad \phi(v) := \mathcal{N}(v - v_D), \quad v \in V_1,
\]
is linear, monotone and continuous (hence maximal monotone) on \( V_1 \). Moreover, if we identify \( V_1 \) with \( V_1^* \) through \( I - \varepsilon \Delta \), we have \( \phi = D\Phi_\varepsilon \) in the sense of Fréchet, where
\[
\Phi_\varepsilon : V_1 \to [0, +\infty), \quad \Phi_\varepsilon(v) := \frac{1}{2} \int_D |\nabla \mathcal{N}(v - v_D)|^2 + \frac{\varepsilon}{2} \int_D |v - v_D|^2, \quad v \in V_1.
\]

**Proof.** The map \( \phi \) is well defined by definition of \( \mathcal{N} \), and is trivially continuous and linear: hence, we only have to check monotonicity. For every \( v \in V_1 \), by definition of \( \mathcal{N} \) we have
\[
(\phi(v), v)_{1,\varepsilon} = \int_D \mathcal{N}(v - v_D)v + \varepsilon \int_D \nabla \mathcal{N}(v - v_D) \cdot \nabla v
= \int_D \mathcal{N}(v - v_D)(-\Delta \mathcal{N}(v - v_D) + v_D) + \varepsilon \int_D \nabla \mathcal{N}(v - v_D) \cdot \nabla (v - v_D)
= \int_D |\nabla \mathcal{N}(v - v_D)|^2 + v_D \int_D \mathcal{N}(v - v_D) + \varepsilon \int_D |v - v_D|^2
= \int_D |\nabla \mathcal{N}(v - v_D)|^2 + \varepsilon \int_D |v - v_D|^2 = 2\Phi_\varepsilon(v) \geq 0.
\]
Hence, \( \phi \) is maximal monotone and a similar computation shows that \( \phi = \partial \Phi_\varepsilon \). Since \( \phi \) is also linear and continuous, \( \Phi_\varepsilon \) is Fréchet differentiable and \( D\Phi_\varepsilon = \phi \).

We test \((3.6)\) by \( \phi(u_\lambda - B_\varepsilon \cdot W) \), where \( B_\varepsilon := (I - \varepsilon \Delta)^{-1}B \), and we obtain
\[
\Phi_\varepsilon(u_\lambda - B_\varepsilon \cdot W)(t) - \int_{Q_1} (-\Delta u_\lambda + \beta_\lambda(u_\lambda) + \pi(u_\lambda) - g) \Delta \phi(u_\lambda - B_\varepsilon \cdot W) = \Phi_\varepsilon(u_0).
\]

Now, note that
\[
u_\lambda - B_\varepsilon \cdot W - (u_\lambda - B_\varepsilon \cdot W)_D = u_\lambda - B_\varepsilon \cdot W - (u_0)_D = u_\lambda - m_\varepsilon,
\]
hence, rearranging the terms we have
\[
\|\nabla \mathcal{N}(u_\lambda - m_\varepsilon)(t)\|^2_H + \varepsilon \| (u_\lambda - m_\varepsilon)(t)\|^2_H \\
+ 2 \int_{Q_t} (-\Delta u_\lambda + \beta_\lambda(u_\lambda) + \pi(u_\lambda) - g)(u_\lambda - m_\varepsilon) \\
= \|\nabla \mathcal{N}(u_0 - (u_0)_D)\|^2_H + \varepsilon \| u_0 - (u_0)_D\|^2_H.
\]
Integrating by parts we infer that
\[
\int_{Q_t} \beta_\lambda(u_\lambda)u_\lambda = \int_{Q_t} \beta_\lambda(u_\lambda)(I + \lambda \beta)^{-1}u_\lambda + \lambda \int_{Q_t} |\beta_\lambda(u_\lambda)|^2 \\
\geq \int_{Q_t} \hat{\beta}((I + \lambda \beta)^{-1}u_\lambda) + \int_{Q_t} \hat{\beta}^{-1}(\beta_\lambda(u_\lambda))
\]
while the Young inequality on the right-hand side yields
\[
\int_{Q_t} \nabla u_\lambda \cdot \nabla m_\varepsilon \leq \frac{1}{4} \int_{Q_t} |\nabla u_\lambda|^2 + \int_Q |\nabla m_\varepsilon|^2,
\]
\[
\int_{Q_t} \beta_\lambda(u_\lambda)m_\varepsilon = \int_{Q_t} \frac{1}{2} \beta_\lambda(u_\lambda)(2m_\varepsilon) \leq \frac{1}{2} \int_{Q_t} \hat{\beta}^{-1}(\beta_\lambda(u_\lambda)) + \int_Q \hat{\beta}(2m_\varepsilon)
\]
Moreover, by the Lipschitz continuity of \(\pi\) and thanks to the properties of \(\|\cdot\|_*\) we have, for every \(\sigma > 0\),
\[
\int_{Q_t} (g - \pi(u_\lambda))(u_\lambda - m_\varepsilon) \leq \frac{1}{2} \int_{Q_t} |u_\lambda - m_\varepsilon|^2 + \int_Q |g|^2 + C^2_\pi \int_{Q_t} |u_\lambda|^2 \\
\leq \left(\frac{1}{2} + 2C^2_\pi\right) \int_{Q_t} |u_\lambda - m_\varepsilon|^2 + \int_Q |g|^2 + 2C^2_\pi \int_Q |m_\varepsilon|^2 \\
\leq \sigma \int_{Q_t} |\nabla (u_\lambda - m_\varepsilon)|^2 + C_\sigma \int_0^t \| (u_\lambda - m_\varepsilon)(s)\|^2_* ds + \int_Q |g|^2 + 2C^2_\pi \int_Q |m_\varepsilon|^2 \\
\leq 2\sigma \int_Q |\nabla u_\lambda|^2 + 2\sigma \int_Q |\nabla m_\varepsilon|^2 + C_\sigma \int_0^t \| (u_\lambda - m_\varepsilon)(s)\|^2_* ds + \int_Q |g|^2 + 2C^2_\pi \int_Q |m_\varepsilon|^2.
\]
Choosing \(\sigma > 0\) sufficiently small, using the Gronwall lemma and rearranging all the terms, we deduce that for every \(t \in [0, T]\)
\[
\|u_\lambda(t)\|^2_* + \varepsilon \|u_\lambda(t)\|^2_H \\
+ \int_{Q_t} |\nabla u_\lambda|^2 + \int_{Q_t} \left(\hat{\beta}((I + \lambda \beta)^{-1}u_\lambda) + \hat{\beta}^{-1}(\beta_\lambda(u_\lambda))\right) \\
\lesssim \|u_0\|^2_* + \varepsilon \|u_0\|^2_H + \|g\|_{L^2(Q)} + \|m_\varepsilon\|^2_{C^0([0,T]};V^*_1) + \varepsilon \|m_\varepsilon\|^2_{C^0([0,T];H)} \\
+ \|m_\varepsilon\|^2_{L^2(0,T;V^*_1)} + \int_Q \hat{\beta}(2m_\varepsilon),
\]
where the implicit constant is independent of both \( \lambda \) and \( \varepsilon \). Now note that the right-hand side is finite for every \( \omega \in \Omega' \); indeed, since \( m_\varepsilon = (u_0)_D + B_\varepsilon \cdot W \), by the contraction properties of \((I - \varepsilon \Delta)^{-1}\) on \( V_1^* \), \( H \) and \( V_1 \) we have
\[
\|m_\varepsilon\|_{C^0([0,T];V_1^*)} \leq \|u_0\|_{V_1^*} + \|B \cdot W\|_{C^0([0,T];V_1^*)},
\]
\[
\|m_\varepsilon\|_{C^0([0,T];H)} \leq \|u_0\|_H + \|B \cdot W\|_{C^0([0,T];H)},
\]
\[
\|\nabla m_\varepsilon\|_{L^2(0,T;H)} \leq \|\nabla B \cdot W\|_{L^2(0,T;H)},
\]
while the contraction property of \((I - \varepsilon \Delta)^{-1}\) on \( L^\infty(D) \) yield
\[
\int_Q \beta(2m_\varepsilon) = \int_Q \beta \left( \frac{1}{2} \|u_0\|_D + \frac{1}{2} \|B_\varepsilon \cdot W\| \right) \leq \frac{1}{2} \int_Q \beta(4\|u_0\|_D) + \frac{1}{2} \int_Q \beta(4\|B \cdot W\|_{L^\infty(Q)}).
\]
The right-hand sides are finite in \( \Omega' \) thanks to the assumptions on \( u_0 \) and \( B \). We deduce that for every \( \omega \in \Omega' \), there is \( M_\omega > 0 \), independent of \( \lambda \) and \( \varepsilon \), such that
\[
\|u_\lambda(\omega})\|_{C^0([0,T];V_1^*)} + \|\nabla u_\lambda(\omega})\|_{C^0([0,T];H)} \leq M_\omega,
\]
\[
\|\|\beta((I + \lambda \beta)^{-1} u_\lambda(\omega))\|_{L^1(Q)} + \|\beta^{-1}(\nabla u_\lambda(\omega))\|_{L^1(Q)} \leq M_\omega.
\]

Let us perform the second estimate now. We test (3.6) by \( u_\lambda - B_\varepsilon \cdot W \):
\[
\frac{1}{2} \|u_\lambda(t) - B_\varepsilon \cdot W(t)\|_1^2 - \int_{Q_t} (-\Delta u_\lambda + \beta u_\lambda + \pi(u_\lambda) - g)\Delta(u_\lambda - B_\varepsilon \cdot W) = \frac{1}{2} \|u_0\|_{1,\varepsilon}^2.
\]
Now, rearranging the terms we have
\[
\|u_\lambda(t)\|_{H}^2 + \|\nabla u_\lambda(t)\|_{H}^2 + \int_{Q_t} |\Delta u_\lambda|^2 + \int_{Q_t} \beta'(u_\lambda) |\nabla u_\lambda|^2
\]
\[
\lesssim \|u_0\|_{H}^2 + \|\nabla u_0\|_{H}^2 + \|B_\varepsilon \cdot W(t)\|_{H}^2 + \|\nabla B_\varepsilon \cdot W(t)\|_{H}^2
\]
\[
+ \int_{Q_t} \Delta u_\lambda \Delta B_\varepsilon \cdot W - \int_{Q_t} \beta(u_\lambda) \Delta B_\varepsilon \cdot W + \int_{Q_t} (\pi(u_\lambda) - g)\Delta(u_\lambda - B_\varepsilon \cdot W),
\]
so that the Young inequality, the regularities of \( g \) and \( B \) and the fact that \((I - \varepsilon \Delta)^{-1}\) is non-expansive on \( H \), \( V_1 \) and \( V_2 \) yield
\[
\|u_\lambda(t)\|_{H}^2 + \|\nabla u_\lambda(t)\|_{H}^2 + \int_{Q_t} |\Delta u_\lambda|^2
\]
\[
\lesssim \|u_0\|_{H}^2 + \|\nabla u_0\|_{H}^2 + \|B \cdot W\|_{C^0([0,T];H)} + \|\nabla B \cdot W\|_{C^0([0,T];H)}
\]
\[
+ \|B \cdot W\|_{L^2(0,T;V_2)}^2 + \|g\|_{L^2(0,T;H)}^2 + C_\pi \int_{Q_t} |u_\lambda|^2 - \int_{Q_t} \beta(u_\lambda) \Delta B_\varepsilon \cdot W,
\]
where the implicit constants are independent of both \( \lambda \) and \( \varepsilon \). Noting that
\[
- \int_{Q_t} \beta(u_\lambda) \Delta B_\varepsilon \cdot W \leq \int_Q \beta^{-1}(\beta(u_\lambda)) + \int_Q \beta(\|\Delta B \cdot W\|_{L^\infty(Q)}),
\]
all the terms on the right-hand side are finite in \( \Omega' \). Hence, for every \( \omega \in \Omega' \) we also have
\[
\|u_\lambda(\omega})\|_{C^0([0,T];H)} + \|\nabla u_\lambda(\omega})\|_{C^0([0,T];H)} + \|u_\lambda(\omega})\|_{L^2(0,T;V_2)} \leq M_\omega.
\]
Furthermore, for every \( \varphi \in V_4 \) and a.e. \( t \in (0, T) \), since \( V_4 \hookrightarrow W^{2,\infty}(D) \) we have

\[
\langle A_\lambda(t, u_\lambda(t)), \varphi \rangle_{V_2} = -\int_D (-\Delta u_\lambda(t) + \beta_\lambda(u_\lambda(t))) + \pi(u_\lambda(t)) - g(t)) \Delta \varphi \\
\lesssim \left( \| \Delta u_\lambda(t) \|_H + \| \beta_\lambda(u_\lambda(t)) \|_{L^1(D)} + C_\pi \| u_\lambda(t) \|_H + \| g(t) \|_H \right) \| \varphi \|_{V_4},
\]

so that by (3.7)–(3.9) and by comparison in (3.6)

\[
\| \partial_t (u_\lambda - B_\varepsilon \cdot W)(\omega) \|_{L^1(0,T;V_4^*)} \leq M_\omega.
\]  

### 3.3 Estimates in expectation

We prove here estimates in expectations on the approximated solutions: the idea is to re-perform the same estimates of Section 3.2 using Itō’s formula instead of a path-by-path argument.

Bearing in mind Lemma 3.3 due to the linearity and continuity of \( \phi \), we have that \( \Phi_\varepsilon \in C^2(V_1) \). It is clear that \( \Phi \) and \( D\Phi_\varepsilon = \phi \) are bounded on bounded subsets of \( V_1 \), and the second Fréchet derivative of \( \Phi_\varepsilon \), i.e.

\[
D^2 \Phi_\varepsilon = D\phi : V_1 \to \mathcal{L}(V_1, V_1), \quad v \mapsto \phi, \quad v \in V_1,
\]

is constant in \( V_1 \). Moreover, the restriction of \( \phi \) to \( V_2 \) is linear and continuous from \( V_2 \) to itself. Hence, we can apply Itô’s formula to \( \Phi_\varepsilon(u_\lambda) \) in the variational framework (cf. [57, Thm. 4.2, p. 65]), which yields, for every \( t \in [0, T] \), \( \mathbb{P} \)-almost surely,

\[
\Phi_\varepsilon(u_\lambda(t)) + \int_0^t \langle A_\lambda(s, u_\lambda(s)), \phi(u_\lambda(s)) \rangle_{V_2} \, ds = \Phi_\varepsilon(u_0) + \frac{1}{2} \int_0^t \text{Tr} (B_\varepsilon^*(s) \phi B_\varepsilon(s)) \, ds + \int_0^t (\phi(u_\lambda(s)), B_\varepsilon(s) \, dW(s))_{1,\varepsilon}.
\]

Rearranging the terms and using the same computations based on the Young inequality and the Lipschitz continuity of \( \pi \) as in Section 3.2 we deduce that

\[
\|(u_\lambda - m)(t)\|_s^2 + \varepsilon \|(u_\lambda - m)(t)\|_H^2 \\
+ \int_{Q_t} |\nabla u_\lambda|^2 + \int_{Q_t} \beta((I + \lambda \beta)^{-1} u_\lambda) + \int_{Q_t} \beta^{-1}(\beta_\lambda(u_\lambda)) \\
\lesssim \|u_0\|_s^2 + \varepsilon \|u_0\|_H^2 + \int_Q |\nabla m|^2 + \int_Q \beta(2m) + \int_Q |g|^2 + \int_Q |m|^2 + \int_{Q_t} |u_\lambda - m|^2 \\
+ \int_0^t \text{Tr} (B_\varepsilon^*(s) \phi B_\varepsilon(s)) \, ds + \int_0^t (\phi(u_\lambda(s)), B_\varepsilon(s) \, dW(s))_{1,\varepsilon}.
\]

Now, by the properties of \( \| \cdot \|_s \) we have

\[
\int_{Q_t} |u_\lambda - m|^2 \leq \sigma \int_{Q_t} |\nabla (u_\lambda - m)|^2 + C_\sigma \int_0^t \|(u_\lambda - m)(s)\|_s^2 \, ds
\]
for every $\sigma > 0$. Moreover, if $(e_k)_k$ is a complete orthonormal system of $U$, we have

$$\text{Tr}(B^*_\varepsilon \phi B\varepsilon) = \sum_{k=0}^{\infty} (\phi B\varepsilon e_k, B\varepsilon e_k)_{1,\varepsilon} \leq \|\phi\|_{\mathcal{X}(V_1, V_1)} \sum_{k=0}^{\infty} \|B\varepsilon e_k\|_{1,\varepsilon} \leq \|B\|_{\mathcal{L}(U, V_1^*)}^2.$$ 

Taking supremum in time and expectations, we estimate the last term on the right-hand side using the Burkholder-Davis-Gundy and Young inequalities as

$$\mathbb{E} \sup_{t \in [0, T]} \int_0^t (\phi(u_\lambda)(s), B\varepsilon(s) dW(s))_{1,\varepsilon} \leq \mathbb{E} \left( \int_0^T \|\phi(u_\lambda(s))\|_{1,\varepsilon}^2 \|B\varepsilon(s)\|_{\mathcal{L}(U, V_1, \varepsilon)}^2 ds \right)^{1/2}$$

$$\leq \mathbb{E} \left( \sup_{t \in [0, T]} \|\phi(u_\lambda(t))\|_{1,\varepsilon} \int_0^T \|B\varepsilon(s)\|_{\mathcal{L}(U, V_1, \varepsilon)}^2 ds \right)$$

$$\leq \sigma \mathbb{E} \sup_{t \in [0, T]} \|\phi(u_\lambda(t))\|_{1,\varepsilon}^2 + C_\sigma \mathbb{E} \int_0^T \|B(s)\|_{\mathcal{L}(U, V_1^*)}^2 ds,$$

where, by definition of $\mathcal{N}$,

$$\|\phi(u_\lambda)\|_{1,\varepsilon}^2 = \|\mathcal{N}(u_\lambda - m)\|_H^2 + \varepsilon \|\nabla \mathcal{N}(u_\lambda - m)\|_H^2 \leq \|u_\lambda - m\|_H^2 + \varepsilon \|u_\lambda - m\|_H^2,$$

where all the implicit constants are independent of $\lambda$ and $\varepsilon$. Choosing $\sigma$ sufficiently small, rearranging the terms and using the Gronwall lemma yield

$$\|u_\lambda - m\|_{L^2(\Omega; C^0([0, T], V_1^*))} + \varepsilon \|u_\lambda - m\|_{L^2(\Omega; C^0([0, T]; H))} + \mathbb{E} \int_Q |\nabla u_\lambda|^2$$

$$+ \mathbb{E} \int_Q \tilde{\beta}((I + \lambda \beta)^{-1} u_\lambda) + \mathbb{E} \int_Q \tilde{\beta}^{-1}(\beta_\lambda(u_\lambda)) \lesssim \mathbb{E} \|u_0\|_H^2 + \varepsilon \mathbb{E} \|u_0\|_H^2$$

$$+ \|B\|_{L^2(\Omega; L^2(0, T; V_1^*))}^2 + \|m\|_{L^2(\Omega; L^2(0, T; V_1^*)})^2 + \left\|\tilde{\beta}(2m)\right\|_{L^2(\Omega \times Q)} + \|g\|_{L^2(\Omega \times Q)}.$$
By the Burkholder-Davis-Gundy and Young inequality we have
\[
\mathbb{E} \sup_{s \in [0,t]} \int_0^s (u_\lambda(s), B_\varepsilon(s))_{1,\varepsilon} \, dW(s) \lesssim \sigma \mathbb{E} \sup_{s \in [0,t]} \|u_\lambda(s)\|_{1,\varepsilon}^2 + C_\sigma \mathbb{E} \int_0^t \|B_\varepsilon(s)\|_{L^2(U,V_{1,\varepsilon})}^2 \, ds
\]
for every \( \sigma > 0 \): hence, recalling also that
\[
\|B_\varepsilon\|_{L^2(U,V_{1,\varepsilon})}^2 \leq \|B\|_{L^2(U,V_1)}^2,
\]
taking supremum in time and expectations, choosing \( \sigma > 0 \) sufficiently small, rearranging the terms thanks to the Young inequality and the Lipschitz-continuity of \( \pi \) yield
\[
\mathbb{E} \sup_{s \leq t} (\|u_\lambda(s)\|_H^2 + \varepsilon \|\nabla u_\lambda(s)\|_H^2) + \mathbb{E} \int_{Q_t} |\Delta u_\lambda|^2 
\lesssim \|u_0\|_{1,\varepsilon}^2 + \mathbb{E} \int_{Q_t} |g|^2 + C_\varepsilon \mathbb{E} \int_{Q_t} |u_\lambda|^2 + \|B\|_{L^2(\Omega;L^2(0,T;\mathbb{L}^2(U,V_1)))}^2.
\]

The Gronwall lemma implies that there exists \( M > 0 \), independent of \( \lambda \) and \( \varepsilon \), such that
\[
\|u_\lambda\|_{L^2(\Omega;C^0([0,T];H))}^2 + \varepsilon \|\nabla u_\lambda\|_{L^2(\Omega;C^0([0,T];H))}^2 + \|u_\lambda\|_{L^2(\Omega;L^2(0,T;V_2))}^2 \leq M.
\] (3.13)

### 3.4 The passage to the limit

Let us fix \( \omega \in \Omega' \). First of all, by the estimate (3.9) and the fact that \( B \cdot W(\omega) \in C^0([0,T]; V_2) \), we have that \( (u_\lambda - B_\varepsilon \cdot W)_\lambda \) is bounded in \( L^2(0,T; V_2) \). Hence, recalling also (3.10), since \( V_2 \hookrightarrow V_1 \) compactly, thanks to the classical compactness results by Aubin-Lions and Simon (see [62, Cor. 4, p. 85]) we infer that
\[
(u_\lambda(\omega))_\lambda \quad \text{is relatively compact in} \quad L^2(0,T;V_1).
\]

Secondly, since \( \beta^{-1} \) is superlinear, the estimate (3.9) yields that \( (\beta_\lambda(u_\lambda(\omega)))_\lambda \) is uniformly integrable in \( Q \), hence also weakly relatively compact in \( L^1(Q) \) by the Dunford-Pettis theorem.

Taking these remarks into account, by (3.7)–(3.10) we deduce that there are
\[
u_\omega \in L^\infty(0,T;H) \cap L^2(0,T;V_2), \quad \varepsilon u_\omega \in L^\infty(0,T;V_1), \quad \xi(\omega) \in L^1(Q)
\]
and a subsequence \( \lambda' = \lambda'(\omega) \) of \( \lambda \) such that, as \( \lambda' \searrow 0 \),
\[
u_\lambda' \xrightarrow{\ast} \nu_\omega \quad \text{in} \quad L^\infty(0,T;H),
\]
\[
\nu_\lambda \to \nu_\omega \quad \text{in} \quad L^2(0,T;V_2),
\]
\[
\varepsilon \nu_\lambda' \xrightarrow{\ast} \varepsilon u_\omega \quad \text{in} \quad L^\infty(0,T;V_1),
\]
\[
u_\lambda' \to \nu_\omega \quad \text{in} \quad L^2(0,T;V_1),
\]
\[
\beta_\lambda'(u_\lambda(\omega)) \to \xi(\omega) \quad \text{in} \quad L^1(Q).
\]

From the strong convergence (3.10) and the Lipschitz-continuity of \( \pi \) it easily follow that
\[
\pi(u_\lambda(\omega)) \to \pi(u(\omega)) \quad \text{in} \quad L^2(0,T;H).
\]
Moreover, owing to the result [5, Thm. 18, p. 126] by Brézis on the strong-weak closure of maximal monotone graphs, the strong convergence of \( u_\lambda(\omega) \) and the weak convergence of \( \beta_\lambda(u_\lambda(\omega)) \) ensure also that

\[
\xi(\omega) \in \beta(u(\omega)) \quad \text{a.e. in } Q.
\]

Furthermore, by definition of Yosida approximation and resolvent, since \( (\beta_\lambda(u_\lambda(\omega)))_\lambda \) is bounded in \( L^1(Q) \) and \( u_\lambda(\omega) \to u(\omega) \) in \( L^1(Q) \), we have

\[
\| (I + \lambda\beta)^{-1} u_\lambda(\omega) - u(\omega) \|_{L^1(Q)} \\
\leq \| (I + \lambda\beta)^{-1} u_\lambda(\omega) - u_\lambda(\omega) \|_{L^1(Q)} + \| u_\lambda(\omega) - u(\omega) \|_{L^1(Q)} \\
= \lambda \| \beta_\lambda(u_\lambda(\omega)) \|_{L^1(Q)} + \| u_\lambda(\omega) - u(\omega) \|_{L^1(Q)} \to 0.
\]

Hence, the estimate \( (5,8) \) together with the weak lower semicontinuity of the convex integrands yields

\[
\int_Q \left( \tilde{\beta}(u(\omega)) + \tilde{\beta}^{-1}(\xi(\omega)) \right) \leq \liminf_{\lambda \to 0} \int_Q \left( \tilde{\beta}((I + \lambda\beta)^{-1} u_\lambda(\omega)) + \tilde{\beta}^{-1}(\beta_\lambda(u_\lambda(\omega))) \right) \leq M_{\omega}
\]
so that \( \tilde{\beta}(u(\omega)) + \tilde{\beta}^{-1}(\xi(\omega)) \in L^1(Q) \).

Now, setting \( w := -\Delta u + \xi + \pi(u) - g \), we have that \( w(\omega) \in L^1(Q) \) and \( w_\lambda(\omega) \to w(\omega) \) in \( L^1(Q) \). Consequently, for every \( \varphi \in V_4 \), since \( \Delta \varphi \in V_2 \hookrightarrow L^\infty(D) \), we have

\[
\int_0^t \int_D w_\lambda(\omega, s) \Delta \varphi \, ds \to \int_0^t \int_D w(s) \Delta \varphi.
\]

By comparison in the approximated equation, we deduce that for every \( t \in [0, T] \)

\[
(u_\lambda(\omega, t), \varphi)_{1,\varepsilon} = (u_0, \varphi)_{1,\varepsilon} + \left\langle \int_0^t B(s) \, dW(s), \varphi \right\rangle_{V_1} + \int_{Q_t} w_\lambda \Delta \varphi \\
\to (u_0, \varphi)_{1,\varepsilon} + \left\langle \int_0^t B(s) \, dW(s), \varphi \right\rangle_{V_1} + \int_{Q_t} w \Delta \varphi = (u(\omega, t), \varphi)_{1,\varepsilon},
\]
so that \( u_\lambda(\omega, t) \xrightarrow{\ast} u(\omega, t) \) in \( V_4^* \). Since \( u_\lambda(\omega) \) is bounded in \( L^\infty(0, T; H) \) and \( \varepsilon u_\lambda(\omega) \) is bounded in \( L^\infty(0, T; V_1) \), we deduce that \( u_\lambda(\omega, t) \to u(\omega, t) \) in \( H \) and \( \varepsilon u_\lambda(\omega, t) \to \varepsilon u(\omega, t) \) in \( V_1 \) for every \( t \in [0, T] \). Letting \( \lambda \to 0 \) in the approximated equation and recalling that \( \omega \in \Omega' \) is arbitrary, we infer that, \( \mathbb{P} \)-almost surely,

\[
(u(\omega), \varphi)_{1,\varepsilon} - \int_0^t \int_D w(\omega, s) \Delta \varphi \, ds = (u_0, \varphi)_{1,\varepsilon} + \left\langle \int_0^t B(s) \, dW(s), \varphi \right\rangle_{V_1} \quad \forall \varphi \in V_4.
\]

By comparison in the limit equation together with the fact that \( u \in L^\infty(0, T; H) \) and \( \varepsilon u \in L^\infty(0, T; V_1) \; \mathbb{P} \)-almost surely, we infer that \( u \in C^0_w([0, T]; H) \hookrightarrow C^0([0, T]; V_1^*) \) and \( \varepsilon u \in C^0_w([0, T]; V_1) \hookrightarrow C^0([0, T]; H) \; \mathbb{P} \)-almost surely.

Let us prove now some regularity properties of the triple \( (u, w, \xi) \) with respect to \( \omega \). Indeed, as we have fixed \( \omega \in \Omega' \) in passing to the limit, the subsequences along which we have convergence could possibly depend on \( \omega \), hence any measurability information is lost.
as \( \lambda \searrow 0 \). In order to recover measurability properties for the limiting processes, we first prove that the solution components \( u \) and \( \xi - \xi_D \) satisfying pointwise the limit equation are unique.

Let then \( (u_i, w_i, \xi_i) \) such that, for \( i = 1, 2 \), \( \mathbb{P} \)-almost surely,

\[
\begin{align*}
&u_i \in C^0([0, T]; V_1^*) \cap L^2(0, T; V_2), \quad \varepsilon u_i \in C^0([0, T]; H) \cap L^\infty(0, T; V_1), \\
&w_i, \xi_i \in L^1(Q), \quad w_i = -\Delta u_i + \beta(u_i) + \pi(u_i) - g, \\
&\widehat{\beta}(u_i) + \beta^{-1}(\xi_i) \in L^1(Q), \quad \xi_i \in \beta(u_i) \quad \text{a.e. in } Q,
\end{align*}
\]

\[
(u_i, \varphi)_{1, \varepsilon} - \int_0^T \int_D w_i(s) \Delta \varphi \, ds = (u_0, \varphi)_{1, \varepsilon} + \langle B \cdot W, \varphi \rangle_{V_1} \quad \forall \varphi \in V_4.
\]

Now, thanks to the classical elliptic regularity results, there is \( m \in \mathbb{N} \) such that \( (I - \sigma \Delta)^{-m \cdot 0} \) maps continuously \( L^1(D) \) into \( V_4 \) for every \( \sigma > 0 \). Fixing such \( m \), taking as test function \( \varphi = (I - \sigma \Delta)^{-m}y \) for any arbitrary \( y \in H \), using the fact that \( (I - \sigma \Delta)^{-m} \) is self-adjoint and commutes with \( -\Delta \), we deduce that

\[
\partial_t (u_1^\sigma - u_2^\sigma) - \Delta (w_1^\sigma - w_2^\sigma) = 0 \quad (u_1^\sigma - u_2^\sigma)(0) = 0 \quad \mathbb{P}\text{-a.s. ,}
\]

in the strong sense on \( V_1 \), identified to \( V_1^* \) through \( I - \varepsilon \Delta \), where we have used the superscript \( \sigma \) to denote the action of \( (I - \sigma \Delta)^{-m} \). Testing by the constant 1 it easily follows that \( (u_1^\sigma - u_2^\sigma)_D = 0 \), so that testing by \( \mathcal{N}(u_1^\sigma - u_2^\sigma) \) yields

\[
\| (u_1^\sigma - u_2^\sigma)(t) \|_H^2 + \varepsilon \| (u_1^\sigma - u_2^\sigma)(t) \|_H^2 + \int_{Q_t} (w_1^\sigma - w_2^\sigma)(u_1^\sigma - u_2^\sigma) = 0 \quad \forall t \in [0, T],
\]

from which, by definition of \( \bar{w}_i^\sigma \) and the Lipschitz-continuity of \( \pi \),

\[
\| (u_1^\sigma - u_2^\sigma)(t) \|_H^2 + \varepsilon \| (u_1^\sigma - u_2^\sigma)(t) \|_H^2 + \int_{Q_t} |\nabla (u_1^\sigma - u_2^\sigma)|^2 + \int_{Q_t} (\xi_1^\sigma - \xi_2^\sigma)(u_1^\sigma - u_2^\sigma)
\]

\[
\leq C_\pi \int_{Q_t} |u_1 - u_2|^2 \quad \forall t \in [0, T].
\]

We want to let \( \sigma \to 0 \) in the previous inequality. Thanks to the properties of \( (I - \sigma \Delta)^{-1} \) and the regularity of \( u_1 - u_2 \), it is readily seen that

\[
(u_1^\sigma - u_2^\sigma)(t) \to (u_1 - u_2)(t) \quad \text{in } H \quad \forall t \in [0, T].
\]

and

\[
u_1^\sigma - u_2^\sigma \to u_1 - u_2 \quad \text{in } L^2(0, T; V_1), \quad \xi_1^\sigma - \xi_2^\sigma \to \xi_1 - \xi_2 \quad \text{in } L^1(Q).
\]

Now, since \( \widehat{\beta}^{-1}(\xi_2) \in L^1(Q) \), the symmetry assumption on \( \widehat{\beta} \) ensures that there is \( \delta \in (0, 1) \) such that \( \widehat{\beta}^{-1}(\delta \xi_2) \in L^1(Q) \), as one can easily check. Hence, using the Young inequality, the symmetry of \( \widehat{\beta} \) and the Jensen inequality for the positive operator \( (I - \sigma \Delta)^{-1} \) (see \[39\] for reference), we have that

\[
\begin{align*}
\varepsilon \int_{Q_t} \frac{(u_1^\sigma - u_2^\sigma)^2}{2} & \leq \left( \frac{u_1^\sigma - u_2^\sigma}{2} \right) \left( \frac{u_1^\sigma - u_2^\sigma}{2} \right) + \beta^{-1} \left( \frac{\delta \xi_1^\sigma - \delta \xi_2^\sigma}{2} \right) \\
& \leq c + \beta(u_1^\sigma) + \beta(u_2^\sigma) + \beta^{-1}(\xi_1^\sigma) + \beta^{-1}(-\delta \xi_2^\sigma) + (I - \sigma \Delta)^{-m} \left( c + \beta(u_1) + \beta(u_2) + \beta^{-1}(\xi_1) + \beta^{-1}(-\delta \xi_2) \right)
\end{align*}
\]
for a positive constant $c$ depending only on $\hat{\beta}$. Since the term in bracket on the right-hand side belongs to $L^1(Q)$, the right-hand side converges in $L^1(Q)$ by the properties of the resolvent, hence it is uniformly integrable. Consequently, we deduce that the family \[ \{(\xi_1^\sigma - \xi_2^\sigma)(u_1^\sigma - u_2^\sigma)\}_\sigma \] is uniformly integrable in $Q$. By Vitali’s convergence theorem it follows that
\[
(\xi_1^\sigma - \xi_2^\sigma)(u_1^\sigma - u_2^\sigma) \rightarrow (\xi_1 - \xi_2)(u_1 - u_2) \quad \text{in } L^1(Q).
\]
Letting then $\sigma \rightarrow 0$, we get that, for every $\eta > 0$,
\[
\|(u_1 - u_2)(t)\|_H^2 + \varepsilon\|(u_1 - u_2)(t)\|_H^2 + \int_{Q_t} |\nabla (u_1 - u_2)|^2 + \int_{Q_t} (\xi_1 - \xi_2)(u_1 - u_2)
\leq C_\eta \int_{Q_t} |u_1 - u_2|^2 \quad \forall t \in [0,T].
\]
Since $(u_1 - u_2)_D = 0$, the Poincaré inequality and the Gronwall lemma yield $u_1 = u_2$. By comparison in the equation we obtain then
\[
\int_Q (\xi_1 - \xi_2)\Delta \varphi = 0 \quad \forall \varphi \in V_4.
\]
Choosing $\varphi = \mathcal{N}y$ for any arbitrary $y \in V_2 \cap V_{1,0}$ yields also $\xi_1 - (\xi_1)_D = \xi_2 - (\xi_2)_D$.

The uniqueness of the solution components $u$ and $\xi - \xi_D$ imply by a classical argument of real analysis that the convergence of $u_\lambda$ and $\beta_\lambda(u_\lambda) - \beta_\lambda(u_\lambda)_D$ hold along the entire sequence $\lambda$, independently of $\omega$. This ensures in turn that $u$ is a predictable $V_1$-valued process, progressively measurable and adapted in $V_2$, that $\xi$ is a predictable $L^1(D)$-valued process and that $w$ is progressively measurable and adapted in $L^1(D)$. For a detailed argument of measurability, the reader can refer to [61, § 3.6].

Finally, by the weak-lower semicontinuity of the norms and the convex integrands, the estimates in expectations (3.11)–(3.13) imply that
\[
\begin{align*}
  u &\in L^2(\Omega; C^0([0,T]; V_1^*)) \cap L^2(\Omega \times (0,T); V_2), \\
  \varepsilon u &\in L^2(\Omega; C^0([0,T]; H)) \cap L^2(\Omega; L^\infty(0,T; V_1)), \\
  \xi , w &\in L^1(\Omega \times (0,T) \times D), \quad w = -\Delta u + \xi + \pi(u) - g, \\
  \hat{\beta}(u) + \hat{\beta}^{-1}(\xi) &\in L^1(\Omega \times (0,T) \times D),
\end{align*}
\]
and this completes the proof of existence of solutions with additive noise under the additional assumption (3.1).

### 3.5 Conclusion

As we have anticipated at the beginning of Section 3, we now remove the extra assumption (3.1) on the operator $B$. Let us suppose only that $B$ is a $\mathcal{L}^2(U, V_1^*)$-progressively measurable process such that
\[
B \in L^2(\Omega \times (0,T); \mathcal{L}^2(U, V_1^*)). \quad \text{For every } n \in \mathbb{N}, \text{ let us define the } \mathcal{L}(U, V_1)-\text{valued process}
\[
B_n := (I - 1/n\Delta)^{-3}B \in L^2(\Omega \times (0,T); \mathcal{L}^2(U, V_1)).
\]
which satisfies, as it is readily seen by classical elliptic regularity results, as \( n \to \infty \),

\[
B_n \to B \quad \text{in } L^2(\Omega \times (0, T); L^2(U, V^*_1)).
\]

Now, for every \( n \in \mathbb{N} \), let \((u_n, w_n, \xi_n)\) be the strong solution to the problem \((1.1) - (1.4)\) with respect to the data \((u_0, g, B_n)\), as given by the proof just performed in the previous sections. Going back to Section 3.3 we notice that the estimates in expectation \((3.11) - (3.13)\) only depend on the \(L^2(\Omega \times (0, T); L^2(U, V^*_1))\)-norm of \(B\): hence, since \((B_n)_n\) is uniformly bounded in \(L^2(\Omega \times (0, T); L^2(U, V^*_1))\), by weak lower semicontinuity of the norms we infer that

\[
\|u_n\|^2_{L^2(\Omega; C^{0}([0, T]; V^*_1))} \leq M,
\]

\[
\varepsilon \|u_n\|^2_{L^2(\Omega; C^{0}([0, T]; H))} \leq M,
\]

\[
\left\| \tilde{\beta}(u_n) \right\|_{L^1(\Omega \times Q)} + \left\| \tilde{\beta}^{-1}(\xi_n) \right\|_{L^1(\Omega \times Q)} \leq M.
\]

Let us show a strong convergence for the sequence \((u_n)_n\). We define the operator

\[
\mathcal{L} : L^1(D) \to V^*_4, \quad (\mathcal{L}v, \varphi)_{V^*_4} := \int_D v \Delta \varphi, \quad v \in L^1(D), \quad \varphi \in V_4,
\]

which clearly extends \(\Delta\) to \(L^1(D)\), i.e. \(-\mathcal{L}|_{V_1} = -\Delta\). With this notation, the solutions \((u_n, w_n, \xi_n)\) satisfy

\[
(I - \varepsilon \Delta)u_n - \int_0^s \mathcal{L}w_n(s) \, ds = (I - \varepsilon \Delta)u_0 + \int_0^s B_n(s) \, dW(s) \quad \forall n \in \mathbb{N}.
\]

Now, by elliptic regularity, there is \(m \in \mathbb{N}\) such that \((I - \sigma \Delta)^{-m} \in \mathcal{L}(L^1(D), V_4)\). Taking the difference between the equations at any arbitrary \(n, k \in \mathbb{N}\), applying the operator \((I - \sigma \Delta)^{-m}\) and using the fact that \((I - \sigma \Delta)^{-m}\) commutes with \(\mathcal{L}\), we get

\[
(I - \varepsilon \Delta)(u_n^\sigma - u_k^\sigma) - \int_0^s \Delta(w_n^\sigma - w_k^\sigma)(s) \, ds = \int_0^s (B_n^\sigma - B_k^\sigma)(s) \, dW(s),
\]

where we have used again the superscript \(\sigma\) for the action of the resolvent \((I - \sigma \Delta)^{-m}\). Since \((u_n^\sigma - u_k^\sigma)_D = 0\), the classical Itô’s formula for \(\Phi_\varepsilon(u_n^\sigma - u_k^\sigma)\) then yields, for every \(t \in [0, T]\), \(\mathbb{P}\)-almost surely,

\[
\frac{1}{2} \|u_n^\sigma - u_k^\sigma\|^2_{H^1} + \frac{\varepsilon}{2} \|\nabla(u_n^\sigma - u_k^\sigma)(t)\|^2_{\mathbb{R}^2} + \int_{Q_t} |\nabla(u_n^\sigma - u_k^\sigma)|^2 + \int_{Q_t} (\xi_n^\sigma - \xi_k^\sigma)(u_n^\sigma - u_k^\sigma)
\]

\[
= \int_{Q_t} (\pi(u_n^\sigma) - \pi(u_k^\sigma))(u_n^\sigma - u_k^\sigma)
\]

\[
+ \frac{1}{2} \int_0^t \text{Tr}((I - \varepsilon \Delta)^{-1}(B_n^\sigma - B_k^\sigma)^*(s)(I - \varepsilon \Delta)^{-1}(B_n^\sigma - B_k^\sigma)^*(s)) \, ds
\]

\[
+ \int_0^t \phi(u_n^\sigma - u_k^\sigma)(s) (B_n^\sigma - B_k^\sigma)(s) \, dW(s))_{1, \varepsilon}. \]

Now, by the contraction properties of \((I - \sigma \Delta)^{-1}\) and Lipschitz-continuity of \(\pi\) we have

\[
\int_{Q_t} (\pi(u_n^\sigma) - \pi(u_k^\sigma))(u_n^\sigma - u_k^\sigma) \leq C_\pi \int_{Q_t} |u_n - u_k|^2.
\]
Arguing as in Section 3.3, we infer that

\[ \int_0^t \text{Tr}((I - \varepsilon \Delta)^{-1}(B_n^\sigma - B_k^\sigma)^*(s)\phi(I - \varepsilon \Delta)^{-1}(B_n^\sigma - B_k^\sigma)(s)) \, ds \]

\[ \lesssim \int_0^t \|(B_n^\sigma - B_k^\sigma)(s)\|^2_{L^2(U,V_1^\ast)} \, ds \leq \int_0^t \|(B_n - B_k)(s)\|^2_{L^2(U,V_1^\ast)} \, ds , \]

and similarly, for every \( \delta > 0, \)

\[ \mathbb{E} \sup_{t \in [0,T]} \int_0^t (\phi(u_n^\sigma - u_k^\sigma)(s), (B_n^\sigma - B_k^\sigma)(s) \, dW(s))_{1,\varepsilon} \]

\[ \leq \delta \mathbb{E} \sup_{t \in [0,T]} \left( \|(u_n^\sigma - u_k^\sigma)(t)\|^2_s + \varepsilon \|(u_n^\sigma - u_k^\sigma)(t)\|^2_H \right) + C_\delta \|B_n - B_k\|^2_{L^2(\Omega;L^2(0,T;L^2(U,V_1^\ast)))} . \]

Rearranging the terms, choosing \( \delta \) sufficiently small and using the Gronwall lemma we deduce that

\[ \|(u_n^\sigma - u_k^\sigma)\|^2_{L^2(\Omega;C^0([0,T];V_1^\ast))} + \varepsilon \|u_n^\sigma - u_k^\sigma\|^2_{L^2(\Omega;C^0([0,T];H))} + \|\nabla(u_n^\sigma - u_k^\sigma)\|^2_{L^2(\Omega \times (0,T);H)} \]

\[ + \mathbb{E} \int_Q (\xi_n^\sigma - \xi_k^\sigma)(u_n^\sigma - u_k^\sigma) \lesssim \|B_n - B_k\|^2_{L^2(\Omega;L^2(0,T;L^2(U,V_1^\ast)))} . \]

We want to let \( \sigma \to 0 \) in the last inequality. The first three terms converge to the corresponding ones without \( \sigma \) by the approximation properties of the operator \((I - \sigma \Delta)^{-1}\) (see for example [61, § 3.7]). Proceeding as in the previous section we also have the convergence

\[ (\xi_n^\sigma - \xi_k^\sigma)(u_n^\sigma - u_k^\sigma) \to (\xi_n - \xi_k)(u_n - u_k) \quad \text{in} \quad L^1(\Omega \times Q) , \]

so that letting \( \sigma \to 0 \) and employing the monotonicity of \( \beta \) we infer

\[ \|u_n - u_k\|^2_{L^2(\Omega;C^0([0,T];V_1^\ast))} + \varepsilon \|u_n - u_k\|^2_{L^2(\Omega;C^0([0,T];H))} + \|\nabla(u_n - u_k)\|^2_{L^2(\Omega \times (0,T);H)} \]

\[ \lesssim \|B_n - B_k\|^2_{L^2(\Omega;L^2(0,T;L^2(U,V_1^\ast)))} , \]

where the implicit constant is independent of \( \varepsilon, n \) and \( k \). Since the right-hand side converges to 0 as \( n, k \to \infty \), we deduce the strong convergence for \((u_n)_n\) in the respective spaces. This information together with the estimates obtained at the beginning of this section allows to pass to the limit in the approximated equation as \( n \to \infty \) and deduce the existence of a strong solution for the limit problem, using again classical tools of convex analysis as in the previous section.

### 3.6 Continuous dependence with additive noise

Let \((u_1^0, g_1, B_1)\) and \((u_0^0, g_2, B_2)\) satisfy the assumptions (H1)–(H4) and (2.1)–(2.3). Then testing the equation satisfied by the difference \( u_1 - u_2 \) by the constant 1 it is readily seen that \((u_1 - u_2)_D = 0\). Hence, arguing as in the previous Section 3.3, writing Itô’s formula
for $\Phi(u_1 - u_2)$ we can infer that

$$
\frac{1}{2} \|(u_1 - u_2)(t)\|_*^2 + \frac{\varepsilon}{2} \|(u_1 - u_2)(t)\|_H^2 + \int_{Q_t} |\nabla (u_1 - u_2)|^2 + \int_{Q_t} (\xi_1 - \xi_2)(u_1 - u_2)
$$

$$
= \frac{1}{2} \|(u_0^1 - u_0^2)\|_*^2 + \frac{\varepsilon}{2} \|(u_0^1 - u_0^2)\|_H^2 + \int_{Q_t} (g_1 - g_2 - \pi(u_1) + \pi(u_2))(u_1 - u_2)
$$

$$
+ \frac{1}{2} \int_0^t \text{Tr}((I - \varepsilon\Delta)^{-1}(B_1 - B_2)^*(s)\phi(I - \varepsilon\Delta)^{-1}(B_1 - B_2)(s)) \, ds
$$

$$
+ \int_0^t \left( \phi(u_1 - u_2)(s), (I - \varepsilon\Delta)^{-1}(B_1 - B_2)(s) \, dW(s) \right)_{1,\varepsilon}.
$$

The case $p = 2$ is immediate: estimating the terms on the right-hand side through the Young, Poincaré, Burkholder-Davis-Gundy inequalities exactly as in Section 3.5 yields

$$
\|u_1 - u_2\|^2_{L^2(\Omega;C^0([0,T];V_1^*))} + \varepsilon \|u_1 - u_2\|^2_{L^2(\Omega;C^0([0,T];H))} + \|\nabla (u_1 - u_2)\|^2_{L^2(\Omega;H)}
$$

$$
\lesssim \|u_0^1 - u_0^2\|^2_{L^2(\Omega;V_1^*)} + \|g_1 - g_2\|^2_{L^2(\Omega;H)} + \|B_1 - B_2\|^2_{L^2(\Omega;V_1^*)},
$$

where the implicit constant is independent of $\varepsilon$. In order to prove the result in general for $p \in [1,2]$ it is enough to take the $p/2$-power in Itô’s formula, and proceed in the same way, getting

$$
\|u_1 - u_2\|^p_{L^\infty(0,T;V_1^*)} + \varepsilon^{p/2} \|u_1 - u_2\|^p_{L^2(0,T;H)} + \|\nabla (u_1 - u_2)\|^p_{L^2(0,T;H)}
$$

$$
\lesssim \|(u_0^1 - u_0^2)\|^p_{L^2(0,T;V_1^*)} + \|g_1 - g_2\|^p_{L^2(0,T;V_1^*)} + \|u_1 - u_2\|^p_{L^2(0,T;H)}
$$

$$
+ \left| \int_0^t \text{Tr}((I - \varepsilon\Delta)^{-1}(B_1 - B_2)^*(s)\phi(I - \varepsilon\Delta)^{-1}(B_1 - B_2)(s)) \, ds \right|^{p/2}
$$

$$
+ \sup_{r \in [0,t]} \left| \int_0^r \left( \phi(u_1 - u_2)(s), (I - \varepsilon\Delta)^{-1}(B_1 - B_2)(s) \, dW(s) \right)_{1,\varepsilon} \right|^{p/2}.
$$

It is easy to check that the desired term on the right-hand side is bounded (modulo a positive constant independent of $\varepsilon$) by $\|B_1 - B_2\|^p_{L^2(0,T;\mathscr{L}^2(U,V_1^*))}$. Furthermore, the Burkholder-Davis-Gundy inequality with exponent $p/2$ yields, for every $\sigma > 0$,

$$
\mathbb{E} \sup_{r \in [0,t]} \left| \int_0^r \left( \phi(u_1 - u_2)(s), (B_1 - B_2)(s) \, dW(s) \right)_{1,\varepsilon} \right|^{p/2}
$$

$$
\lesssim \mathbb{E} \left( \int_0^T \|\phi((u_1 - u_2)(s))\|^2_{1,\varepsilon} \|I - \varepsilon\Delta\|_{L^2(U,V_1,\varepsilon)}^2 \, ds \right)^{p/4}
$$

$$
\leq \sigma \mathbb{E} \|u_1 - u_2\|^p_{L^\infty(0,T;V_1^*)} + C_\sigma \mathbb{E} \|B_1 - B_2\|^p_{L^2(0,T;\mathscr{L}^2(U,V_1^*))}.
$$

Taking expectations, choosing $\sigma$ sufficiently small and employing again the Gronwall lemma, we obtain the desired result.

### 3.7 Existence with multiplicative noise

Let us focus now on the multiplicative noise case: let $(u_0,g,B)$ satisfy the assumptions (H1)–(H4) and (2.4)–(2.5). For any progressively measurable $V_1$-valued process
in the hypothesis of the additive noise case, and there exist a strong solution \((u_y, w_y, \xi_y)\) to the problem with respect to the data \((u_0, g, B(y))\). Since the solution component \(u_y\) is unique, for every \(T_0 \in (0, T]\) it is well defined the map

\[
\Gamma : L^2(\Omega \times (0, T_0); V_1) \to L^2(\Omega; C^0([0, T_0]; H)) \cap L^2(\Omega; L^\infty(0, T_0; V_1)) \cap L^2(\Omega \times (0, T_0); V_2)
\]

such that \(\Gamma : y \mapsto u_y\). It is clear that \((u, w, \xi)\) is a strong solution on \([0, T_0]\) with multiplicative noise if and only if \(u\) is a fixed point for \(\Gamma\) and \((w, \xi) = (w_u, \xi_u)\).

Let \(y_1, y_2 \in L^2(\Omega \times (0, T_0); V_1)\) progressively measurable and set \(u_1 := \Gamma(y_1)\) and \(u_2 := \Gamma(y_2)\). Thanks to \((2.6)\) and the fact that \(B\) is \(\mathcal{L}^2(U, V^*_1)\)-valued, we can apply the continuous dependence property proved in Section 3.6 using also the Lipschitz-continuity of \(B\), we have that

\[
\|u_1 - u_2\|^2_{L^2(\Omega; C^0([0, T_0]; V_1^*))} + \varepsilon \|u_1 - u_2\|^2_{L^2(\Omega; C^0([0, T_0]; H))} + \|\nabla(u_1 - u_2)\|^2_{L^2(\Omega \times (0, T_0); H)}
\leq \|B(y_1) - B(y_2)\|^2_{L^2(\Omega; L^2(0, T_0; \mathcal{L}^2(U, V^*_1)))}
\leq \|y_1 - y_2\|^2_{L^2(\Omega; C^0([0, T_0]; V_1^*))} \leq T_0 \|y_1 - y_2\|^2_{L^2(\Omega; C^0([0, T_0]; V_1^*))}.
\]

This shows in particular that, for every \(T_0 \in (0, T]\), the map \(\Gamma\) continuously extends in a canonical way to

\[
\tilde{\Gamma} : L^2(\Omega; C^0([0, T_0]; V_1^*)) \to L^2(\Omega; C^0([0, T_0]; H)) \cap L^2(\Omega \times (0, T_0); V_1)
\]

and that \(\tilde{\Gamma}\) is a contraction on \(L^2(\Omega; C^0([0, T_0]; V_1^*))\) provided that \(T_0\) is chosen sufficiently small. Hence, fixing such \(T_0 > 0\), there exists a unique \(u \in L^2(\Omega; C^0([0, T_0]; V_1^*))\) such that \(u = \tilde{\Gamma} u\). Moreover, since \(u = \tilde{\Gamma} u \in L^2(\Omega \times (0, T_0); V_1)\) by definition of \(\tilde{\Gamma}\), we also deduce that \(u = \Gamma u \in L^2(\Omega; C^0([0, T_0]; H)) \cap L^2(\Omega; L^\infty(0, T_0; V_1)) \cap L^2(\Omega \times (0, T_0); V_2)\) by definition of \(\Gamma\). Hence, \(u\) is a strong solution to the problem with multiplicative noise on \([0, T_0]\) together with some respective solution components \((w, \xi)\) (not necessarily unique). Now a strong solution on the whole interval \([0, T]\) can be obtained by a classical patching argument on the subintervals \([T_0, 2T_0], \ldots, \) until \(T\) iterating the computations just performed.

### 3.8 Continuous dependence with multiplicative noise

Let now \((u^1_0, g_1)\) and \((u^2_0, g_2)\) satisfy (H1)–(H4) and \((2.3)\). The fact that \(B\) takes values in \(\mathcal{L}^2(U, V^*_0)\) and \((2.3)\) imply in particular that

\[
(u^1_0)_D + (B(u_1) \cdot W)_D = (u^2_0)_D + (B(u_2) \cdot W)_D.
\]

Hence, by the continuous dependence result with additive noise case and the Lipschitz continuity of \(B\) we have, for every \(T_0 \in (0, T]\) and \(p \in [1, 2]\),

\[
\|u_1 - u_2\|^p_{L^p(\Omega; C^0([0, T_0]; V^*_1))} + \varepsilon^{p/2} \|u_1 - u_2\|^p_{L^p(\Omega; C^0([0, T_0]; H))} + \|\nabla(u_1 - u_2)\|^p_{L^p(\Omega \times (0, T_0); H)}
\lesssim \|B(u_1) - B(u_2)\|^p_{L^p(\Omega; L^2(0, T_0; \mathcal{L}^2(U, V^*_1)))}
\lesssim \|y_1 - y_2\|^p_{L^p(\Omega; L^2(0, T_0; V^*_1))} \leq T_0^{p/2} \|y_1 - y_2\|^p_{L^p(\Omega; C^0([0, T_0]; V^*_1))},
\]

where all the implicit constants are independent of \(\varepsilon\). Now the continuous dependence result follows choosing again \(T_0\) sufficiently small and by a patching argument.
4 Vanishing viscosity limit as $\varepsilon \searrow 0$

4.1 Additive noise

We begin with the additive noise case: let us work thus in the framework of Theorem 2.6. We recall that $(u_\varepsilon, w_\varepsilon, \xi_\varepsilon)$ are strong solutions to problem (1.1)–(1.4) with respect to $\varepsilon > 0$ and data $(u_0 \varepsilon, g_\varepsilon, B_\varepsilon)$. Note that thanks to the continuous dependence property contained in Theorem 2.2, the solution component $u_\varepsilon$ is uniquely determined.

First of all, we assume that $B$ satisfies the stronger assumption (3.1) and that $(B_\varepsilon)_\varepsilon$ is bounded in the space (3.1): we will show how to remove this further hypothesis later on. Going back to Sections 3.2–3.3 and noting that the estimates (3.7)–(3.12) are independent (positive constant $M$) and similarly, for a positive constant $V$ we fix now $\xi_\varepsilon$ in Section 3.4 we can choose $(\xi_\varepsilon)$ and similarly, for a positive constant $M$ independent of $\varepsilon$ such that

$$
\|u_\varepsilon(\omega)\|^2_{C^0([0,T];V^*_T)} + \varepsilon \|u_\varepsilon(\omega)\|^2_{C^0([0,T];H)} + \|\nabla u_\varepsilon(\omega)\|^2_{L^2(0,T;H)} \leq M_\varepsilon,
$$

$$
\left\|\tilde{\beta}(u_\varepsilon(\omega))\right\|_{L^1(Q)} + \left\|\tilde{\beta}^{-1}(\xi_\varepsilon(\omega))\right\|_{L^1(Q)} \leq M_\varepsilon,
$$

$$
\|u_\varepsilon(\omega)\|^2_{L^2(0,T;H)} + \varepsilon \|\nabla u_\varepsilon(\omega)\|^2_{L^2(0,T;H)} + \|u_\varepsilon(\omega)\|^2_{L^2(0,T;V^*_T)} \leq M_\varepsilon.
$$

and similarly, for a positive constant $M$ independent of $\varepsilon$,

$$
\|u_\varepsilon\|^2_{L^2(\Omega;C^0([0,T];V^*_T))} + \varepsilon \|u_\varepsilon\|^2_{L^2(\Omega;C^0([0,T];H))} + \|\nabla u_\varepsilon\|^2_{L^2(\Omega \times (0,T);H)} \leq M,
$$

$$
\left\|\tilde{\beta}(u_\varepsilon)\right\|_{L^1(\Omega \times Q)} + \left\|\tilde{\beta}^{-1}(\xi_\varepsilon)\right\|_{L^1(\Omega \times Q)} \leq M,
$$

$$
\|u_\varepsilon\|^2_{L^2(\Omega;L^\infty(0,T;H))} + \varepsilon \|\nabla u_\varepsilon\|^2_{L^2(\Omega;L^\infty(0,T;H))} + \|u_\varepsilon\|^2_{L^2(\Omega \times (0,T);V^*_T)} \leq M.
$$

We fix now $\omega \in \Omega'$. By the pathwise estimates, using similar arguments to the ones performed in Section 3.4, we infer the following convergences:

$$
\begin{align*}
&u_\varepsilon(\omega) \xrightarrow{\ast} u(\omega) \text{ in } L^\infty(0,T;H), \quad u_\varepsilon(\omega) \rightarrow u(\omega) \text{ in } L^2(0,T;V^*_2), \\
u_\varepsilon(\omega) \rightarrow u(\omega) \text{ in } L^2(0,T;V^*_1), \quad \varepsilon u_\varepsilon(\omega) \rightarrow 0 \text{ in } L^\infty(0,T;V^*_1), \\
w_\varepsilon(\omega) \rightarrow w(\omega) \text{ in } L^1(Q), \quad \xi_\varepsilon(\omega) \rightarrow \xi(\omega) \text{ in } L^1(Q).
\end{align*}
$$

Arguing again as in Section 3.4 we infer that $u$ is a predictable $H$-valued process, progressively measurable adapted in $V^*_2$ and with continuous trajectories in $V^*_1$. Furthermore, the estimates in expectations yield the desired convergences for $u_\varepsilon$: indeed, the weak convergences are immediate, while the strong convergence follows by a classical consequence of the Severini-Egorov theorem from the fact that $u_\varepsilon \rightarrow u$ in $L^2(0,T;V^*_1)$ $\mathbb{P}$-almost surely and the boundedness of $(u_\varepsilon)_\varepsilon$ in $L^2(\Omega \times (0,T);V^*_1)$. As far as $\xi$ is concerned, proceeding as in Section 3.4 we can choose $\xi$ to be a predictable $L^1(D)$-valued process such that $\xi_\varepsilon \rightarrow \xi$ in $L^1(\Omega \times Q)$. A similar argument holds for $w$. It is also clear using the convergences of $(u_\varepsilon, w_\varepsilon, \xi_\varepsilon)$ that $(u, w, \xi)$ is a strong solution to the problem in the case $\varepsilon = 0$.

We show now that it is not restrictive to assume that (3.1) for the operators $B$ and $(B_\varepsilon)_\varepsilon$. Indeed, if this is not the case, all the estimates in expectation on $(u_\varepsilon, w_\varepsilon, \xi_\varepsilon)$
continue to hold, as they depend only on the $\mathcal{L}^2(U, H)$-regularity of $B$ (see for example Section [3.3]). Hence, the weak convergences in Theorem 2.6 are still true, as well as $\varepsilon u_\varepsilon \to 0$ in $L^2(\Omega; L^\infty(0, T; V_1))$. The problem is the strong convergence of $u_\varepsilon$ in $L^p(\Omega; L^2(0, T; V_1))$. To this end, for every $\delta > 0$ we set $B_\delta := (I - \delta \Delta)^{-2} B$, which satisfies (3.1), and similarly $B_{\varepsilon \delta} := (I - \delta \Delta)^{-2} B_\varepsilon$, which is uniformly bounded in $\varepsilon$ in the space $\text{S}$. Let $(u_{\delta}, w_{\delta}, \xi_{\delta})$ and $(u_\delta, w_\delta, \xi_\delta)$ be any strong solutions with respect to the data $(u_{\delta}, g_{\delta}, B_{\delta})$ and $(u_\delta, g, B_\delta)$, in the cases $\varepsilon > 0$ and $\varepsilon = 0$, respectively: since the first solution component is unique, note that $u_\delta$ and $u_{\varepsilon \delta}$ are uniquely determined. Since we have already proved the convergence result under the stronger assumption (3.1), we have that $u_{\varepsilon \delta} \to u_\delta$ in $L^p(\Omega; L^2(0, T; V_1))$ for every $p \in [1, 2)$ and every $\delta > 0$, as $\varepsilon \searrow 0$. Recalling the compatibility condition (2.10) and the fact that $(I - \delta \Delta)^{-2}$ preserves the mean, by the continuous dependence property of Theorem 2.2 we have

$$
||u_\varepsilon - u||_{L^p(\Omega; L^2(0, T; V_1))} \\
\leq ||u_\varepsilon - u_{\varepsilon \delta}||_{L^p(\Omega; L^2(0, T; V_1))} + ||u_{\varepsilon \delta} - u_{\delta}||_{L^p(\Omega; L^2(0, T; V_1))} + ||u_{\delta} - u||_{L^p(\Omega; L^2(0, T; V_1))} \\
\lesssim ||u_\varepsilon - u_{\varepsilon \delta}||_{L^2(\Omega; C^0([0, T]; V_1^*))} + \|\nabla (u_\varepsilon - u_{\varepsilon \delta})\|_{L^2(\Omega; L^2(0, T; H))} + \|u_{\varepsilon \delta} - u_{\delta}\|_{L^p(\Omega; L^2(0, T; V_1))} \\
+ ||u_{\delta} - u||_{L^2(\Omega; C^0([0, T]; V_1^*))} + \|\nabla (u_{\delta} - u)\|_{L^2(\Omega; L^2(0, T; H))} \\
\lesssim |B_\varepsilon - B_{\varepsilon \delta}|_{L^2(\Omega \times (0,T); L^2(U; V_1^*)^*)} + ||u_{\varepsilon \delta} - u_{\delta}||_{L^p(\Omega; L^2(0, T; V_1))} + ||B_\delta - B||_{L^2(\Omega \times (0,T); L^2(U; V_1^*))} \\
\lesssim |B - B_\varepsilon|_{L^2(\Omega \times (0,T); L^2(U; V_1^*))} + |B - B_\delta|_{L^2(\Omega \times (0,T); L^2(U; V_1^*))} + ||u_{\varepsilon \delta} - u_{\delta}||_{L^p(\Omega; L^2(0, T; V_1))}.
$$

Since $B_\delta \to B$ in $L^2(\Omega \times (0, T); \mathcal{L}^2(U, H))$, the second term on the right-hand side can be made arbitrarily small choosing $\delta$ small enough. With such a choice of $\delta$ (fixed), the first and third terms converge to 0 as $\varepsilon \searrow 0$, so that the strong convergence is proved.

### 4.2 Multiplicative noise

Let us focus now on the multiplicative noise case. We work in the setting of Theorem 2.7 for every $\varepsilon > 0$, let $(u_\varepsilon, w_\varepsilon, \xi_\varepsilon)$ be any strong solution to the problem with $\varepsilon > 0$ with multiplicative noise given by the operator $B$ and with respect to the data $(u_0, g_\varepsilon)$. Let us also denote by $u$ the unique solution component of the limit problem with $\varepsilon = 0$ with multiplicative noise $B$ and data $(u_0, g)$. Going back to Section 3.3 using the linear growth assumption of $B$ it is not difficult to check that the estimates corresponding to (3.11) - (3.13) continue to hold for $(u_\varepsilon, w_\varepsilon, \xi_\varepsilon)$, i.e. there exists $M > 0$ independent of $\varepsilon$ such that

$$
||u_\varepsilon||_{L^2(\Omega; C^0([0, T]; V_1^*))} + \varepsilon ||u_\varepsilon||_{L^2(\Omega; C^0([0, T]; H))} + \|\nabla u_\varepsilon\|_{L^2(\Omega \times (0, T); H)}^2 \leq M ,
$$

$$
\|\beta(u_\varepsilon)\|_{L^1(\Omega \times Q)} + \|\beta^{-1}(\xi_\varepsilon)\|_{L^1(\Omega \times Q)} \leq M ,
$$

$$
||u_\varepsilon||_{L^2(\Omega; L^\infty(0, T; H))}^2 + \varepsilon \|\nabla u_\varepsilon\|_{L^2(\Omega; L^\infty(0, T; H))}^2 + \|u_\varepsilon\|_{L^2(\Omega \times (0, T); V_2)}^2 \leq M .
$$

These readily imply the weak convergences of $(u_\varepsilon, w_\varepsilon, \xi_\varepsilon)$ contained in Theorem 2.7 as well as $\varepsilon u_\varepsilon \to 0$ in $L^2(\Omega; L^\infty(0, T; V_1))$. We only need to prove the strong convergence $u_\varepsilon \to u$ in $L^p(\Omega; L^2(0, T; V_1))$. To this end, we denote by $(\tilde{u}_\varepsilon, \tilde{w}_\varepsilon, \tilde{\xi}_\varepsilon)$ a strong solution to the problem with $\varepsilon > 0$, data given by $(u_0, g)$, and additive noise given by $B(u)$. Note that $B(u)$ is an admissible choice thanks to the regularity of $u$ and the linear growth assumption.
of $B$. Since we have already proved the additive noise case contained in Theorem 2.9 and the solution component $u$ is unique, we have that $\bar{u}_\epsilon \to u$ in $L^p(\Omega; L^2(0, T; V_1))$ as $\epsilon \to 0$.

For this reason, it is natural to show that the difference $u_\epsilon - \bar{u}_\epsilon$ converges to 0: since $B$ is $L^2(\Omega, H_0)$-valued, the continuous dependence property for the problem with additive noise and $\epsilon > 0$ and the Lipschitz continuity of $B$ yield

$$
\|u_\epsilon - \bar{u}_\epsilon\|_{L^p(\Omega; L^2(0, T; V_1))} \leq \|u_\epsilon - \bar{u}_\epsilon\|_{L^p(\Omega; C^0([0, T]; V_1^*)')} + \|\nabla (u_\epsilon - \bar{u}_\epsilon)\|_{L^p(\Omega; L^2(0, T; H))}
$$

$$
\lesssim \|B(u_\epsilon) - \bar{B}(u)\|_{L^p(\Omega; L^2(0, T; L^2(U, V_1^*)))} \lesssim \|u_\epsilon - u\|_{L^p(\Omega; L^2(0, T; V_1^*))}
$$

$$
\leq \|u_\epsilon - \bar{u}_\epsilon\|_{L^p(\Omega; L^2(0, T; V_1^*))} + \|\bar{u}_\epsilon - u\|_{L^p(\Omega; L^2(0, T; V_1^*))}.
$$

Since $T$ is arbitrary and we already know that the last term on the right-hand side converges to 0, the Gronwall lemma implies that $u_\epsilon - \bar{u}_\epsilon \to 0$ in $L^p(\Omega; L^2(0, T; V_1))$, from which the required convergence result. As in the case of additive noise, it is straightforward now to check that $(u, w, \xi)$ is a strong solution to the problem with multiplicative noise in the case $\epsilon = 0$ and data $(u_0, g)$.

## 5 Regularity

In this last section we prove the regularity results contained in Theorems 2.9–2.10.

### 5.1 The first result

Let us focus on the proof of Theorem 2.9. Suppose that $(u_0, g, B)$ have finite $p$-moments for a certain $p \in [2, +\infty)$ as in the assumptions (2.12)–(2.13). Then we argue going back to Section 3.3 in the proof of estimate (3.13), we take the $\frac{p}{2}$-power of Itô’s formula for the square of the $\|\cdot\|_{1, \epsilon}$-norm. Proceeding as in Section 3.3 we get

$$
\mathbb{E}\|u_\lambda\|_{L^p(0, t; H)}^p + \epsilon^{p/2}\mathbb{E}\|\nabla u_\lambda\|_{L^\infty(0, t; H)}^p + \mathbb{E}\|\Delta u_\lambda\|_{L^2(0, t; H)}^p
$$

$$
\lesssim \mathbb{E}\|u_0\|_{L^p(\Omega; V_1)}^p + \mathbb{E}\|g\|_{L^p(0, t; H)}^p + C_\pi \mathbb{E}\|u_\lambda\|_{L^2(0, t; H)}^p + \mathbb{E}\|B\|_{L^p(0, t; L^2(U, V_1^*))}^p,
$$

from which the desired estimate follows thanks to the Gronwall lemma.

Let us show now the additional regularities for $w$ and $\xi$ in the viscous case $\epsilon > 0$. First of all, recalling that $\beta$ has cubic growth by assumption, it easily follows that

$$
\|\beta_\lambda(u_\lambda)\|_{L^2(0, t; H)} \lesssim 1 + \|u_\lambda\|_{L^p(0, t; L^5(D))}^3 \lesssim 1 + \|u_\lambda\|_{L^\infty(0, t; V_1)}^3,
$$

and by comparison also

$$
\|w_\lambda\|_{L^2(0, t; H)} \lesssim 1 + \|u_\lambda\|_{L^\infty(0, t; V_1)}^3.
$$

These readily imply that the families $(w_\lambda)_\lambda$ and $(\beta_\lambda(u_\lambda))_\lambda$ are uniformly bounded in the space $L^{p/3}(\Omega; L^2(0, T; H))$, from which the thesis follows.

Finally, note that if $\beta \in W^{1, \infty}_{loc}(\mathbb{R})$ and $\beta'$ has quadratic growth, then

$$
|\nabla \beta_\lambda(u_\lambda)| = \beta'_\lambda(u_\lambda)|\nabla u_\lambda| \lesssim (1 + |u_\lambda|^2)|\nabla u_\lambda|,
$$
so that by the estimates already performed, the Hölder inequality and the fact that \(V_1 \equiv L^0(D)\) we can infer that

\[
\| \nabla \beta_\lambda(u_\lambda) \|_{L^2(0,T;H)}^2 \lesssim 1 + \int_Q |u_\lambda|^4 \| \nabla u_\lambda \|^2 \leq 1 + \int_0^T \| |u_\lambda|^4 \|_{L^3/2(D)} \| \| \nabla u_\lambda \|_{L^3(D)}^2 \lesssim 1 + \| u_\lambda \|_{L^\infty(0,T;V_1)}^2 \| u_\lambda \|_{L^2(0,T;V_2)}^2 ,
\]

which yields

\[
\| \nabla \beta_\lambda(u_\lambda) \|_{L^2(0,T;H)} \lesssim 1 + \| u_\lambda \|_{L^\infty(0,T;V_1)}^2 \| u_\lambda \|_{L^2(0,T;V_2)}^2,
\]

with implicit constant independent of \(\lambda\) and \(\varepsilon\). Since \((u_\lambda)\) is uniformly bounded in \(L^r(\Omega; L^2(0,T;V_2))\) and \(L^p(\Omega; L^\infty(0,T;V_1)\), we deduce by Hölder inequality that the right-hand is bounded in \(L^r(\Omega)\), with \(\frac{1}{r} = \frac{2}{p} + \frac{1}{q} = \frac{2}{p}\), i.e. for \(r = p/3\).

### 5.2 The second result

Let us turn the attention to Theorem 5.10. As we have anticipated, the idea is to write a Itô-type formula for the free-energy functional associated to the system. We start with the viscous case \(\varepsilon > 0\).

Let \((u, w, \xi)\) be the strong solution to the problem, as in the setting of Theorem 5.10. Note that in this framework there is uniqueness of all the three solution components since \(\beta\) is assumed to be single-valued, hence the uniqueness of \(u\) implies the uniqueness of \(\xi\), and consequently of \(w\). From Section 3 we know that \((u, w, \xi)\) can be obtained as limit in suitable topologies of some approximated solutions \((u_\lambda, w_\lambda, \xi_\lambda)\) solving the problem where \(\beta\) is replaced by its Yosida approximation \(\beta_\lambda\) and \(\xi_\lambda = \beta_\lambda(u_\lambda)\). If we denote the action of the resolvent \((I - \sigma \Delta)^{-2}\) by the superscript \(\sigma\), for every \(\sigma > 0\), we have that

\[
du_\lambda^\sigma - \Delta (I - \varepsilon \Delta)^{-1} w_\lambda^\sigma \, dt = (I - \varepsilon \Delta)^{-1} B^\sigma \, dW , \quad u_\lambda^\sigma(0) = u_0^\sigma ,
\]

in the strong sense on \(V_1\) with the dualization given by the operator \((I - \varepsilon \Delta)^{-1}\), and not only in the variational way on \((V_2, V_1, V_2^*)\). Recall that \(w_\lambda^\sigma = -\Delta u_\lambda^\sigma + \beta_\lambda(u_\lambda)^\sigma + \pi(u_\lambda)^\sigma - g^\sigma\). We define similarly \(w_\lambda^\sigma := -\Delta u_\lambda^\sigma + \beta_\lambda(u_\lambda^\sigma) + \pi(u_\lambda^\sigma) - g\).

We show here some further uniform estimates on \((u_\lambda, w_\lambda, \beta_\lambda(u_\lambda))\) using the Ginzburg-Landau free-energy functional. It is natural to consider the regularized version of the functional \(E\) defined as

\[
E_\lambda : V_1 \to [0, +\infty) , \quad E_\lambda(y) := \frac{1}{2} \int_D |\nabla y|^2 + \int_D \beta_\lambda(y) + \int_D \pi(y) , \quad y \in V_1 .
\]

Let us show that \(E_\lambda \in C^2(V_1)\). It is clear that \(E_\lambda\) is Fréchet-differentiable with

\[
DE_\lambda : V_1 \to V_1^* , \quad DE_\lambda(y) = -\Delta y + \beta_\lambda(y) + \pi(y) , \quad y \in V_1 ,
\]

from which it follows that \(E_\lambda \in C^1(V_1)\). Moreover, using the fact that \(V_1 \equiv L^4(D)\), it is not difficult to check that \(DE_\lambda\) is Fréchet-differentiable with

\[
D^2 E_\lambda : V_1 \to \mathcal{L}(V_1, V_1^*) , \quad D^2 E_\lambda(y)[h_1, h_2] = \int_D \nabla h_1 \cdot \nabla h_2 + \int_D (\beta_\lambda(y) + \pi(y)) h_1 h_2 ,
\]
for \( y, h_1, h_2 \in V_1 \). It follows in particular that \( \mathcal{E}_\lambda \) and \( D\mathcal{E}_\lambda \) are bounded on bounded subsets of \( V_1 \), and that \( D\mathcal{E}_\lambda \) has linear growth. Moreover, from the equation it also follows that

\[
D\mathcal{E}_\lambda(u^\delta_\lambda) = -\Delta u^\delta_\lambda + \beta_\lambda(u^\delta_\lambda) + \pi(u^\delta_\lambda) = w^\delta_\lambda + g.
\]

Now, note that the expressions above for \( D\mathcal{E}_\lambda \) and \( D^2\mathcal{E}_\lambda \) are intended in the spaces \( V_1^* \) and \( \mathcal{L}(V_1, V_1^*) \), respectively, i.e. not identifying \( V_1 \) with \( V_1^* \). If we use the dualization of \( V_1 \) given by \((I - \varepsilon\Delta)^{-1}\), which is the one where the equation in \( u^\varepsilon \) is intended, we have

\[
D\mathcal{E}_\lambda(u^\delta_\lambda) = (I - \varepsilon\Delta)^{-1}(w^\delta_\lambda + g),
\]

\[
D^2\mathcal{E}_\lambda(u^\delta_\lambda) = -\Delta(I - \varepsilon\Delta)^{-1} + (I - \varepsilon\Delta)^{-1} (h \mapsto (\beta'_\lambda(u^\delta_\lambda) + \pi'(u^\delta_\lambda))h, \ h \in V_1).
\]

Taking these remarks into account, Itô’s formula for \( \mathcal{E}_\lambda(u^\varepsilon_\lambda) \) yields, for every \( t \in [0, T] \),

\[
\frac{1}{2} \int_D |\nabla u^\varepsilon_\lambda(t)|^2 + \int_D \hat{\beta}_\lambda(u^\varepsilon_\lambda(t)) + \int_D \hat{\pi}(u^\varepsilon_\lambda(t)) + \int_{Q_t} |\nabla w^\varepsilon_\lambda|^2 \cdot \nabla(w^\varepsilon_\lambda + g)
\]

\[
= \frac{1}{2} \int_D |\nabla u^\varepsilon_0|^2 + \int_D \hat{\beta}(u^\varepsilon_0) + \int_D \hat{\pi}(u^\varepsilon_0)
\]

\[
+ \int_0^t \left( (I - \varepsilon\Delta)^{-1}(w^\varepsilon_\lambda + g), (I - \varepsilon\Delta)^{-1}B^\varepsilon(s) dW(s) \right)_{1, \varepsilon}
\]

\[
+ \int_0^t \sum_{k=0}^\infty \int_D |\nabla(I - \varepsilon\Delta)^{-1}B^\varepsilon(s)e_k|^2 ds
\]

\[
+ \int_0^t \sum_{k=0}^\infty \int_D (\pi'(u^\varepsilon_\lambda(s)) + \beta_\lambda'(u^\varepsilon_\lambda(s)))|(I - \varepsilon\Delta)^{-1}B^\varepsilon(s)e_k|^2 ds,
\]

where \((e_k)\) is a complete orthonormal system of \( U \). Taking into account the Lipschitz-continuity of \( \pi \) and rearranging the terms we infer

\[
\frac{1}{2} \int_D |\nabla u^\varepsilon_\lambda(t)|^2 + \int_D \hat{\beta}_\lambda(u^\varepsilon_\lambda(t)) + \int_D \hat{\pi}(u^\varepsilon_\lambda(t)) + \int_{Q_t} |\nabla w^\varepsilon_\lambda|^2 \lesssim 1 + \|u_0\|^2_{V_1} + \int_D \hat{\beta}(u^\varepsilon_0)
\]

\[
+ \int_Q |\nabla g|^2 + \| (I - \varepsilon\Delta)^{-1}B \|_{L^2(0,T;L^2(U, V_1))}^2 + \int_{Q_t} |\nabla(w^\varepsilon_\lambda - w^\varepsilon_\lambda)|^2
\]

\[
+ \int_0^t \langle (w^\varepsilon_\lambda + g)(s), (I - \varepsilon\Delta)^{-1}B^\varepsilon(s) dW(s) \rangle_{V_1} + \sum_{k=0}^\infty \int_{Q_t} \beta_\lambda'(u^\varepsilon_\lambda(s))|(I - \varepsilon\Delta)^{-1}B^\varepsilon e_k|^2,
\]

where the implicit constant is independent of \( \lambda, \sigma \) and \( \varepsilon \). Let us show how to control the stochastic integral. To this end, note that for every \( k \in \mathbb{N} \)

\[
\langle w^\varepsilon_\lambda + g, (I - \varepsilon\Delta)^{-1}B^\varepsilon e_k \rangle_{V_1} = \langle w^\varepsilon_\lambda - (w^\varepsilon_\lambda)_D, (I - \varepsilon\Delta)^{-1}B^\varepsilon e_k \rangle_{V_1} + \langle (w^\varepsilon_\lambda)_D (Be_k)_D \nabla \rangle \lesssim \langle w^\varepsilon_\lambda - w^\varepsilon_\lambda + g, (I - \varepsilon\Delta)^{-1}B^\varepsilon e_k \rangle_{V_1},
\]

so that thanks to the Burkholder-Davis-Gundy, Poicaré and Young inequalities, we deduce
that, for every $\eta > 0$,
\[
\mathbb{E} \sup_{r \in [0,t]} \left| \int_0^t \langle (w_\lambda^\sigma + g)(s), (I - \varepsilon \Delta)^{-1} B^\sigma (s) dW(s) \rangle \right|_{V_1}^{q/2} \\
\lesssim \mathbb{E} \left( \int_0^t \left\| \nabla w_\lambda^\sigma (s) \right\|_{L^2(V_1)}^2 \left\| (I - \varepsilon \Delta)^{-1} B(s) \right\|_{L^2(U,V_1^*)}^2 \, ds \right)^{q/4} \\
+ \|B\|_{L^\infty(\Omega \times (0,T);L^2(U,V_1^*))}^q \mathbb{E} \left\| (w_\lambda^\sigma)_D \right\|_{L^2(U,V_1)}^{q/2} \\
+ \mathbb{E} \left( \int_0^t \left( \left\| w_\lambda^\sigma - w_\lambda^\sigma + g(s) \right\|_{V_1}^2 \left\| (I - \varepsilon \Delta)^{-1} B(s) \right\|_{L^2(U,V_1^*)}^2 \, ds \right)^{q/4} \\
\lesssim \eta \mathbb{E} \| \nabla w_\lambda^\sigma \|_{L^2(Q_t)}^q + \| w_\lambda^\sigma - w_\lambda^\sigma \|_{L^2(\Omega;L^2(0,T;V_1))}^q + \| g \|_{L^\infty(\Omega;L^2(0,T;V_1))}^q \\
+ \|B\|_{L^\infty(\Omega \times (0,T);L^2(U,V_1^*))}^q \mathbb{E} \sup_{s \in [0,t]} |(w_\lambda)_D|_{V_1}^{q/2} \\
+ \mathbb{E} \left( \sum_{k=0}^{\infty} \int_{Q_t} \beta_k^\sigma (s) \left| (I - \varepsilon \Delta)^{-1} B^\sigma e_k \right|^2 \right)^{q/2},
\]
where again the implicit constant is independent of $\lambda$, $\sigma$ and $\varepsilon$. Let us estimate now the last term according to the different assumptions of Theorem 2.10, we do not go through the details as the argument is similar to the one performed in [11 § 5]. Under assumption 2.21, we can write $(I - \varepsilon \Delta)^{-1} B = B_1^\varepsilon + B_2^\varepsilon$ for some $B_1^\varepsilon \in L^q(\Omega \times (0,T);L^2(U,H))$ and $B_2^\varepsilon \in L^q(0,T;L^\infty(\Omega;L^2(U,V_1)))$. Hence, using the fact that $V_2 \hookrightarrow L^\infty(D)$ and that $\beta'$ has quadratic growth, we get
\[
\mathbb{E} \left( \sum_{k=0}^{\infty} \int_{Q_t} \beta_k^\sigma (s) \left| (B_1^\varepsilon)^\sigma e_k \right|^2 \right)^{q/2} \lesssim \left( 1 + \| u_\lambda \|_{L^\infty(\Omega;L^2(0,T;V_2))} \right) \| B_1^\varepsilon \|_{L^\infty(\Omega \times (0,T);L^2(U,H))}^q,\]
while by the H"older inequality and the fact that $V^\infty \hookrightarrow L^3(D)$
\[
\mathbb{E} \left( \sum_{k=0}^{\infty} \int_{Q_t} \beta_k^\sigma (s) \left| (B_2^\varepsilon)^\sigma e_k \right|^2 \right)^{q/2} \lesssim \int_0^t \| B_2^\varepsilon \|_{L^q(\Omega;L^2(0,T;L^2(U,H)))}^q \mathbb{E} \left( \int_0^t \| u_\lambda^\sigma (s) \|_{L^6(D)}^2 \sum_{k=0}^{\infty} \| B_2^\varepsilon (s) e_k \|_{L^3(D)}^2 \, ds \right)^{q/4} \lesssim \int_0^t \| B_2^\varepsilon \|_{L^q(\Omega;L^2(0,T;L^2(U,H)))}^q \mathbb{E} \sup_{r \leq s} \| u_\lambda^\sigma (r) \|_{V_1}^q \, ds.
\]
Otherwise, if (2.22) is in order, using the fact that \( V_s \in L^\infty(D) \) for \( s > \frac{N}{2} \) thanks to the Sobolev embeddings, by the growth assumption on \( \beta \) we have that
\[
\mathbb{E} \left( \sum_{k=0}^{\infty} \int_{Q_t} \beta'_\lambda(u^\sigma_s)(I - \varepsilon\Delta)^{-1}B^\sigma e_k^2 \, ds \right)^{q/2} \lesssim \|(I - \varepsilon\Delta)^{-1}B\|_{L^q(\Omega; L^2(0,T; \mathcal{L}^2(U,H)))}^q \\
+ \int_0^t \|(I - \varepsilon\Delta)^{-1}B(s)\|_{L^q(\Omega; \mathcal{L}^2(U,V_s))}^q \mathbb{E} \sup_{r \leq s} \left( \int_D \tilde{\beta}_\lambda(u^\sigma_r(r)) \right)^{q/2} \, ds.
\]
Hence, it is clear that in both cases the terms on the right-hand side can be handled using the Gronwall lemma and the terms on the left-hand side. Finally, recalling the definition of \( w^\sigma_\lambda \), by the growth assumption on \( \beta \) and the Lipschitz-continuity of \( \pi \) we have
\[
(w^\sigma_\lambda)_D = (w^\sigma_\lambda)_D + (w^\gamma_\lambda - w^\sigma_\lambda)_D = (\beta_\lambda(u^\sigma_\lambda) + (\pi(u^\sigma_\lambda))D - gD + (w^\gamma_\lambda - w^\sigma_\lambda)_D \\
\lesssim 1 + \int_D \tilde{\beta}_\lambda(u^\sigma_\lambda) + \|u^\sigma_\lambda\|_H^2 + \|g\|_H^2 + \|w^\gamma_\lambda - w^\sigma_\lambda\|_H^2.
\]
Going back then to Itô’s inequality and using the Gronwall lemma, we deduce that there exists \( T_0 \in (0,T] \) sufficiently small, independent of \( \lambda, \sigma \) and \( \varepsilon \), such that
\[
\mathbb{E} \sup_{s \in [0,T_0]} \|u^\sigma_\lambda(s)\|_{V_1}^q + \mathbb{E} \sup_{s \in [0,T_0]} \left\| \tilde{\beta}_\lambda(u^\sigma_\lambda(s)) \right\|_{L^1(D)}^{q/2} \\
+ \mathbb{E} \sup_{s \in [0,T_0]} \left| (w^\sigma_\lambda)_D \right|^{q/2} + \|\nabla w^\sigma_\lambda\|_{L^q(\Omega; L^2(0,T_0; H))}^q \\
\lesssim C_\varepsilon \left( 1 + \|g\|_{L^q(\Omega; L^2(0,T; V_1))}^q + \| \beta_\lambda(u^\sigma_\lambda) \|_{L^q(\Omega; L^2(0,T; \mathcal{L}^2(U,V_1)))}^q \\
+ \|B\|_{L^q(\Omega; L^q(0,\lambda; \mathcal{L}^2(U,V_1)))}^q \right),
\]
where \( C_\varepsilon \) is a positive constant, independent of \( \lambda \) and \( \sigma \), depending only on the norms of \( (I - \varepsilon\Delta)^{-1}B \) in the spaces given by the assumptions (2.21) or (2.22).

Now, let us fix \( \varepsilon, \lambda > 0 \): the only dependence on \( \sigma \) is contained in the last term on the right-hand side. In particular, we have
\[
w^\sigma_\lambda - w^\sigma_\lambda = \beta_\lambda(u^\lambda)^\sigma - \beta_\lambda(u^\sigma_\lambda) + \beta_\lambda(u^\sigma_\lambda) - \beta_\lambda(u^\sigma_\lambda) + \pi(u^\sigma_\lambda) - \pi(u^\sigma_\lambda) + g^\sigma - g.
\]
By the regularity of \( g \) we have that \( g^\sigma \to g \) in \( L^q(\Omega; L^2(0,T; V_1)) \), while the Lipschitz-continuity of \( \beta_\lambda \) and \( \pi \) imply that \( w^\sigma_\lambda - w^\sigma_\lambda \to 0 \) in \( L^q(\Omega; L^2(0,T; H)) \), as \( \sigma \to 0 \). Furthermore, as \( \lambda \) is fixed, it is not difficult to check that \( \beta_\lambda(u^\sigma_\lambda) \to \beta_\lambda(u^\sigma_\lambda) \) in \( L^q(\Omega; L^2(0,T; V_1)) \) provided that \( \beta_\lambda \in C^1(\mathbb{R}) \): in general this is not granted by the definition of Yosida approximation. However, it can be obtained by a further regularization on the problem (for example considering a smoothed version of the Yosida approximation which preserves monotonicity). Since we are still arguing with \( \lambda \) fixed, a further approximation would not be restrictive, hence we omit it for brevity. A similar argument holds for the term in \( \pi \). Taking these remarks into account and letting \( \sigma \to 0 \), we get by lower semicontinuity
\[
\mathbb{E} \sup_{s \in [0,T_0]} \|u^\lambda(s)\|_{V_1}^q + \mathbb{E} \sup_{s \in [0,T_0]} \left\| \tilde{\beta}_\lambda(u^\lambda(s)) \right\|_{L^1(D)}^{q/2} \\
+ \mathbb{E} \sup_{s \in [0,T_0]} \left| (w^\lambda)_D \right|^{q/2} + \|\nabla w^\lambda\|_{L^q(\Omega; L^2(0,T_0; H))}^q \\
\lesssim C_\varepsilon \left( 1 + \|(I - \varepsilon\Delta)^{-1}B\|_{L^q(\Omega; L^2(0,T; \mathcal{L}^2(U,V_1)))}^2 \right).
\]
with implicit constant independent of \( \lambda \) and \( \varepsilon \), and \( C_\varepsilon \) as before. Recalling that \( T_0 \) is independent of both \( \lambda \) and \( \varepsilon \), by a classical patching argument we infer that

\[
\|u_\lambda\|_{L^q(\Omega;L^\infty(0,T;V_1))}^q + \left\| \tilde{\beta}(u_\lambda) \right\|_{L^{q/2}(\Omega;L^{\infty}(0,T;L^1(D)))} \leq M_\varepsilon,
\]

\[
\left\| (w_\lambda)_D \right\|_{L^{q/2}(\Omega;L^{\infty}(0,T))} + \left\| \nabla w_\lambda \right\|_{L^q(\Omega;L^2(0,T;\mathcal{H})))} \leq M_\varepsilon,
\]

where \( M_\varepsilon > 0 \) only depends on the norms of \((I-\varepsilon\Delta)^{-1}B\) in the spaces given the respective assumptions in Theorem 2.10. Recalling that \( \|\cdot\|_1 \) is an equivalent norm in \( V_1 \), we deduce in particular that

\[
\|w_\lambda\|_{L^{q/2}(\Omega;L^2(0,T;V_1))} \leq M_\varepsilon.
\]

Moreover, using the growth assumption on \( \beta \), we also deduce by comparison that

\[
\|\beta_\lambda(u_\lambda)\|_{L^{q/2}(\Omega;L^\infty(0,T;L^1(D)))} \cap L^{q/2}(\Omega;L^2(0,T;\mathcal{H})) \leq M_\varepsilon.
\]

Completing now the proof of existence as in Section 3, taking into account the estimates above yields the desired regularity result.

In order to prove the result for the pure case, it is immediate to check that if \( \varepsilon = 0 \) then (2.19)–(2.22) imply that \( M_\varepsilon \) is uniformly bounded in \( \varepsilon \), so that we can conclude easily thanks to the convergence result in Theorem 2.6.

Finally, let us prove the last sentence of Theorem 2.10. By the results already proved, we know in particular that \( u \in L^\infty(0,T;V_1) \) \( \mathbb{P} \)-almost surely. Hence, if (2.21) is in order we have that \( \beta_\lambda(u) \in L^\infty(0,T;V_1) \) and

\[
|\nabla \beta_\lambda(u)| = \beta'_\lambda(u)|\nabla u| \lesssim (1 + |u|^2)|\nabla u|,
\]

from which the Hölder inequality and the Sobolev embedding theorems yield

\[
\|\nabla \beta_\lambda(u)\|_{L^2(0,T;\mathcal{H})}^2 \lesssim 1 + \int_Q |u|^4|\nabla u|^2 \leq 1 + \int_0^T \|u\|_{L^4(D)}^4 \|\nabla u\|_{L^4(D)}^2 \leq 1 + \int_0^T \|u\|_{L^6(D)}^4 \|\nabla u\|_{L^6(D)}^2 \lesssim 1 + \|u\|_{L^\infty(0,T;V_2)}^4 \|u\|_{L^{2}(0,T;\mathcal{V}_2)}^2,
\]

where the right-hand side is finite \( \mathbb{P} \)-almost surely. We deduce by Hölder inequality that the family \((\nabla \beta_\lambda(u(\omega)))_\lambda \) is uniformly bounded in \( L^{4/3}(\Omega;L^2(0,T;\mathcal{H})) \), which implies that \( \nabla \xi \in L^{4/3}(\Omega;L^2(0,T;\mathcal{H})) \). The thesis then follows by comparison in the equation and by elliptic regularity.
