Background: An association between idiopathic pulmonary fibrosis (IPF) and advancing age is suspected since IPF occurs primarily in patients over 60 years of age. Though, little is known about the disease in the elderly. The aim of this study was to characterize elderly IPF patients using data from the longitudinal, German-wide INSIGHTS-IPF registry.

Methods: Patients were grouped into elderly (≥75 years) and nonelderly IPF (<75 years) at the time of enrollment into the study. Baseline clinical characteristics, comorbidities, health related quality of life (HRQoL), medical therapy and survival were compared between age groups. Effects of antifibrotic therapy on forced vital capacity (FVC) were analyzed over 24 months.

Results: Of 1,009 patients, 350 (34.7%) were ≥75 years old. Elderly IPF patients compared to younger patients had a higher number of comorbidities (3.6 ± 2.5 vs. 2.8 ± 2.3; p < 0.001). The mean ± SD EQ-5D score (0.64 ± 0.21 vs. 0.69 ± 0.21; p = 0.005), and the overall WHO-5 score (13.1 ± 5.9 vs. 14.3 ± 6.0; p = 0.015) were significantly lower while the UCSD-SOBQ (52.6 ± 31.2 vs. 45.5 ± 31.2; p = 0.030) was significantly higher in elderly patients, indicating a more impaired HRQoL and more breathlessness. At baseline, 55.4% of elderly and 56.8% of nonelderly patients with IPF were treated with antifibrotic therapy (p = 0.687). For FVC decline after initiation of antifibrotic therapy, there was neither a significant difference between age groups at the different time points over 24 months (beta: 0.41; 95%-CI: −0.98 to 1.81; p = 0.563) nor over the whole course of time (beta: −0.05; 95%-CI: −0.20 to 0.09; p = 0.478). All-cause mortality was higher in elderly patients (49.1 vs. 37.9%; HR 1.65; 95%-CI 1.36–2.00; p < 0.001). Antifibrotic therapy was associated with improved survival in IPF patients, independent from age (<75 years: beta 0.76; 95%-CI: 0.59–0.99; p = 0.049; ≥75 years: beta 0.71; 95%-CI: 0.51–0.96; p = 0.043).
Conclusion: In real life, a significant proportion of IPF patients are ≥75 years old, characterized by higher number of comorbidities and global reduced HRQoL. However, the effect of an antifibrotic therapy was similar between age groups and associated with a survival benefit emphasizing the importance for an early antifibrotic therapy in IPF, independent from age.

Keywords: aging, elderly, antifibrotic therapy, prognosis, multivariate analysis

INTRODUCTION

Idiopathic pulmonary fibrosis (IPF) is a chronic interstitial lung disease (ILD) characterized by clinical symptoms such as dyspnea, cough and increasing immobility (1). IPF occurs primarily in patients over 60 years of age (1, 2), for which reason a connection with aging processes has been suspected. The aging lung is subject to biological changes which make it more susceptible to disease. Recently, genetic alterations have been identified which are associated with an increased risk for the development of IPF, but may also increase the risk of other lung diseases associated with aging such as chronic obstructive pulmonary disease (COPD) or lung cancer (3). Although the exact relationship between aging and the pathogenesis of IPF is still unclear, there are a number of processes, which can be found in the disease including telomerase shortening, cell aging, mitochondrial dysfunction, and dysregulation of the extracellular matrix (4, 5).

Additionally, the advanced age of patients with IPF in general is associated with a higher number of comorbidities and reduced quality of life. Indeed, studies have shown that patients with IPF often suffer from comorbidities (6, 7), which may also be due to advanced age.

IPF is a disease with dismal prognosis. For only a few years now, there are two antifibrotic drugs approved that, while they cannot cure the disease, can slow down the loss of forced vital capacity (FVC). A subgroup analysis of the INPULSIS trials detected no differences between patients below and above the age of 65 years in the primary endpoint (annual rate of decline in FVC) and key secondary endpoints [change from baseline in St. George’s Respiratory Questionnaire (SGRQ) total score or time to first acute exacerbation] in patients treated with nintedanib vs. placebo (8). However, it is unclear if antifibrotic therapy is consistently initiated and effective in IPF patients over the age of 75 years, and if the effect also can be reproduced outside randomized controlled trials, under real-life conditions.

The aim of our study was to characterize elderly patients with IPF (≥75 years) in comparison to younger IPF patients with respect to comorbidities and quality of life. Further, we wanted to evaluate the use of antifibrotic therapy and its effect on lung function and survival in elderly compared to younger patients with IPF.

METHODS

Study Population

The INSIGHTS-IPF ("Investigating significant health trends in idiopathic pulmonary fibrosis") is a German, nationwide, investigator-initiated cohort study (registered at Clinicaltrials.gov NCT01695408). Since November 2012, patients with IPF have continuously been enrolled in routine clinical care in 19 pulmonary specialist centers in Germany. Patients are eligible if they are ≥18 years old, have a study-site diagnosis of IPF following the 2011 international IPF guideline and have provided written informed consent (9). The study was approved by the Ethics Committee of the Medical faculty, Technical University, Dresden, Germany in 2012, and by additional local ethics committees in accordance with local requirements. The methodology and structure of the registry as well as a detailed description of the baseline characteristics have been reported previously (9–11). The ongoing INSIGHTS-IPF study has no explicit exclusion criteria. Clinical data are collected at the initial enrollment, and thereafter every 6–12 months. Clinical events like hospitalization, acute exacerbation (as judged by the treating physician) and death are recorded at these follow-up visits. For the data collection an internet-based, secure case report form (eCRF) was used. For the present analysis, all patients from the INSIGHTS-IPF registry with at least one follow-up assessment were included. The last patient of our analysis was included on December 11, 2019. Data cut-off date was on April 29, 2020. Based on the age at enrollment patients were grouped into “elderly IPF” (≥75 years) and “nonelderly IPF” (<75 years).

Clinical Data

At baseline and the study visits (every 6–12 months), routine pulmonary function tests were performed and different measures were documented, including FVC % predicted, diffusing capacity of the lung for carbon monoxide (DLCO) % predicted, the forced expiratory volume in 1 s (FEV1), and six-minute walk distance (6MWD). Based on lung function, age and gender, the Gender, Age, Physiology (GAP) index was calculated (12). Based on clinical judgement of overall disease course, when possible, the
treating physician categorized the patient as stable disease, slow progression, rapid progression (10).

A range of comorbidities was documented and recorded at baseline. Based on these pre-selected comorbidities, the individual number of comorbidities was calculated.

Specific therapy, including formerly used immunosuppressants, anticoagulation, antibiotic therapy, and long-term oxygen were documented at baseline and thereafter during study visits. For the follow-up analysis of FVC decline under antibiotic therapy only patients, in whom an antifibrotic therapy was newly started, were eligible.

**HRQoL**

To evaluate health-related quality of life (HRQoL) the St. George’s Respiratory Questionnaire (SGRQ) and the University of California San Diego Shortness of Breath Questionnaire (UCSD SOB) were applied as described in detail before (13, 14). In addition, the World Health Organization-5 Well-Being Index (WHO-5) was used. Based on 5 items, the WHO-5 is a short questionnaire evaluating well-being. The total score range from 0 to 25, whereby lower scores correspond to a lower level of general healthcare and cost-utility (1). In addition, the World Health Organization-5 Well-Being Index (WHO-5) was used. Based on 5 items, the WHO-5 is a short questionnaire evaluating well-being. The total score range from 0 to 25, whereby lower scores correspond to a lower level of well-being. A score below 13 can indicate a possible depression. Further, the EuroQol five-dimensional questionnaire (EQ-5D), generated by the EuroQol group, is used for evaluation of general healthcare and cost-utility (15). It consists of five domains (mobility, self-care, usual activities, pain or discomfort, and anxiety or depression) and a visual analog scale (VAS). A sum utility score can be calculated based on the five domain scores, which range from 0 to 1 (perfect health state). The scores of the VAS range from 0 (health state equivalent to death) to 100 (best imaginable health state).

**Data Analysis**

Continuous variables are presented as the mean ± standard deviation (SD), and categorical variables are summarized by frequency and percentage. Continuously distributed sociodemographic and clinical parameters were compared by a t-test between nonelderly and elderly patients. A Chi-square test was used to compare categorical parameters between the two groups. The risk of mortality was investigated by a multivariable Cox proportional hazard model for overall mortality in the total sample and separately in nonelderly and elderly patients. For survival analysis, patients who underwent lung transplantation were censored at the time of lung transplantation. Potential predictor variables for overall mortality were assessed in univariable analyses. All parameters with a significance level of p < 0.10 were included in the multivariable model. All treatment episodes with antifibrotic therapy (nintedanib or pirfenidone) were identified at enrollment and during follow-up in the registry. There was no pre-defined treatment threshold for initiation of an antifibrotic therapy. Patients with a maximum visit of 20 days before and 20 days after the start of antifibrotic therapy were selected for the analyses of the course of FVC % pred. after start of antifibrotic therapy as described previously (16). Since the date of the start of an antifibrotic therapy did not necessarily correspond exactly to the study visit date, the lung function values at the start of antifibrotic therapy were extracted from the visits +/- 20 days before the start of therapy. The change in FVC % pred. up to 24 months after therapy start was analyzed by a generalized linear mixed model. Data management and statistical analyses were conducted with use of STATA 12.1 (StataCorp LP. Stata Statistical Software: Release 12. College Station, TX, USA).

**RESULTS**

**Patient Characteristics**

Of 1,009 patients enrolled in the INSIGHTS IPF registry until December 2019, 350 (34.7%) were ≥75 years of age. The most common initial symptoms in elderly and nonelderly patients with IPF were dyspnea (86.3 and 85.7%; p = 0.811) and cough (68.3 and 72.8%; p = 0.128). Basilarcrackles were found in 80.0% of elderly and 82.4% of nonelderly patients (p = 0.350) on auscultation. Baseline characteristics of elderly and nonelderly IPF patients are shown in **Table 1**. There were marked differences with regard to mean age at enrollment (78.6 ± 3.1 years vs. 65.4 ± 7.4 years; p < 0.001), age at symptoms onset (75.4 ± 5.1 years vs. 61.6 ± 8.8 years; p < 0.001), age at IPF diagnosis (76.8 ± 4.7 years vs. 65.3 ± 8.3 years; p < 0.001) and duration since first IPF symptoms (3.1 ± 3.7 years vs. 3.8 ± 4.3 years; p < 0.026) between elderly and nonelderly IPF patients. At baseline, elderly IPF patients had significantly higher FVC (70.6 ± 17.4% pred. vs. 66.2 ± 18.8% pred.; p < 0.001) and FEV1 (79.9 ± 18.5% pred. vs. 73.6 ± 19.4% pred.; p < 0.001) and lower DLCo (34.3 ± 14.0% pred. vs. 36.8 ± 17.1% pred.; p = 0.030) or PaO2 (67.1 ± 10.7 mmHg vs. 69.3 ± 11.7 mmHg; p = 0.010), respectively. The mean ± SD BMI of elderly IPF was lower (26.7 ± 3.9 vs. 27.9 ± 4.3; p < 0.001) with less patients suffering from obesity (18.6 vs. 27.3%; p < 0.001).

UIP pattern was found in 64.3% of elderly and in 60.0% of nonelderly IPF patients. A possible UIP pattern was present in 25.7% of elderly and 29.6% of nonelderly patients and a HRCT inconsistent with UIP was found in 1.1% of elderly and 1.1% of nonelderly patients. In 8.9% of elderly and 9.0% of nonelderly patients no information on the HRCT pattern was provided. The diagnosis of IPF was more often based on HRCT (91.1 vs. 86.3%; p = 0.025) in elderly IPF and less patients had undergone surgical lung biopsy/histology (20.0 vs. 41.3%; p < 0.001). In elderly patients, there were no difference between patients without surgical lung biopsy and patients with surgical lung biopsy in terms of FVC (70.5 ± 17.7% pred. vs. 71.4 ± 16.2% pred.; p = 0.821), DLCO (33.7 ± 14.2% pred. vs. 37.3% pred.; p = 0.105), PaO2 (66.8 ± 10.6 mmHg vs. 68.6 ± 10.6 mmHg; p = 0.302), number of comorbidities (3.6 ± 2.5 vs. 3.5 ± 2.3; p = 0.755), and HRQoL (EQ-5D score: 66.2 ± 24.8 vs. 63.6 ± 20.6; p = 0.469; WHO-5: 13.0 ± 5.9 vs. 13.8 ± 6.3; p = 0.398; SGRQ: 57.8 ± 20.8 vs. 56.3 ± 26.1; p = 0.704). Diagnosis of IPF was based on multidisciplinary discussion in 63.4% of elderly patients and 62.7% of nonelderly patients, while in 15.7% of elderly and 15.8% of nonelderly the diagnosis of IPF was not based on a multidisciplinary discussion. There was no data available if or not a multidisciplinary discussion was performed in 20.9% of elderly and 21.6% of nonelderly IPF.
### TABLE 1 | Baseline characteristics of elderly and nonelderly patients with IPF:

|                          | Age group <75 | Age group ≥75 years | p-value |
|--------------------------|----------------|---------------------|---------|
| **Baseline characteristics of elderly and nonelderly patients with IPF.** | | | |
| **Age group** <75 | 659 | 350 | |
| **Sex, n (%)** | | | |
| Male | 534 (81.0%) | 280 (80.0%) | 0.693 |
| Female | 125 (19.0%) | 70 (20.0%) | |
| **Age in years, mean (sd)** | | | <0.001 |
| 65.4 (7.4) | 78.6 (3.1) | |
| **BMI in kg/m², mean (sd)** | | | <0.001 |
| 27.9 (4.3) | 26.7 (3.9) | |
| Underweight | 5 (0.8%) | 6 (1.7%) | <0.001 |
| Normal weight | 148 (22.5%) | 109 (31.1%) | |
| Overweight | 326 (49.5%) | 170 (48.6%) | |
| Obesity | 180 (27.3%) | 65 (18.6%) | |
| **Smoking status** | | | 0.176 |
| Never | 221 (33.5%) | 131 (37.4%) | |
| Former stopped | 421 (63.9%) | 215 (61.4%) | |
| Current | 17 (2.6%) | 4 (1.1%) | |
| **Age at symptom onset, mean (sd)** | | | <0.001 |
| 61.6 (8.8) | 75.4 (5.1) | |
| **Duration since first IPF symptoms** | | | 0.026 |
| In years, mean (sd) | 3.8 (4.3) | 3.1 (3.7) | |
| **Age at IPF diagnosis, mean (sd)** | | | <0.001 |
| In months, mean (sd) | 23.1 (33.2) | 21.6 (41.3) | 0.537 |
| In years, mean (sd) | 1.9 (2.8) | 1.8 (3.5) | 0.537 |
| <3 months | 200 (31.2%) | 114 (33.3%) | 0.183 |
| 3 to <6 months | 61 (9.5%) | 43 (12.6%) | |
| 6+ months | 381 (59.4%) | 185 (54.1%) | |
| **IPF diagnosis was based on** | | | 0.025 |
| HRCT | 569 (86.3%) | 319 (91.1%) | |
| Surgical lung biopsy/histology | 272 (41.3%) | 70 (20.0%) | 0.248 |
| **Current NYHA class** | | | |
| I | 41 (14.2%) | 11 (8.1%) | |
| II | 120 (41.5%) | 54 (49.7%) | |
| III | 117 (40.5%) | 66 (47.8%) | |
| IV | 11 (3.8%) | 6 (4.4%) | |
| **Current Borg dyspnea index, mean (sd)** | | | 0.493 |
| 2.2 (2.3) | 2.1 (2.2) | |
| **6-min walk distance, mean (sd)** | | | 0.063 |
| 299.3 (196.5) | 275.5 (184.6) | |

| FVC | 66.2 (18.8) | 70.6 (17.4) | 0.001 |
| TLC | 70.2 (20.2) | 69.4 (14.6) | 0.522 |
| DLCO | 36.8 (17.1) | 34.3 (14.0) | 0.030 |
| PaO2 | 69.3 (11.7) | 67.1 (10.7) | 0.010 |
| **Physician’s global assessment of clinical course of IPF** | | | 0.189 |
| Stable disease | 268 (40.7%) | 150 (42.9%) | |
| Slow progression | 173 (26.3%) | 85 (24.3%) | |
| Rapid progression | 62 (9.4%) | 21 (6.0%) | |
| No judgement possible | 156 (23.7%) | 94 (26.9%) | |

Data are presented as mean ± SD, or n (%).

BMI, body mass index; IPF, idiopathic pulmonary fibrosis; HRCT, high resolution computed tomography; NYHA, New York Heart Association; FEV1, forced expiratory volume in 1; FVC, forced vital capacity; TLC, total lung capacity; DLCO, diffusing capacity of the lung for carbon monoxide.

Further, elderly IPF patients had a significantly higher number of comorbidities at baseline (3.6 ± 2.5 vs. 2.8 ± 2.3; p < 0.001; Table 2). Comorbidities that were more prevalent in elderly IPF included left heart failure (10.3 vs. 4.7%; p = 0.001), coronary artery disease (36.9 vs. 22.5%; p < 0.001), peripheral arterial disease (5.4 vs. 2.6%; p = 0.020), atrial fibrillation (15.4 vs.
5.6%; \( p < 0.001 \)), and arterial hypertension (63.4 vs. 50.4%; \( p < 0.001 \)). In contrast, depression and depressive disorder (2.6 vs. 4.9%; \( p = 0.013 \)) were more often seen in nonelderly IPF. At baseline, lung cancer was present in five (1.4%) elderly and eleven (1.7%) nonelderly patients (\( p = 0.771 \)). During the follow-up, two (0.6%) elderly and five (0.8%) nonelderly patients were newly diagnosed with lung cancer (\( p = 0.773 \)).

Medical therapy at baseline is shown in Table 3. Elderly IPF patients were more often on prophylactic (16.3 vs. 7.8%; \( p < 0.001 \)) or therapeutic anticoagulation (18.9 vs. 9.6%; \( p < 0.001 \)) in comparison to nonelderly IPF.

HRQoL was assessed using different standardized questionnaires (Table 4), which were available in 752 patients. The EQ-5D score (0.64 ± 0.21 vs. 0.69 ± 0.21; \( p = 0.005 \)), EQ-5D VAS (56.9 ± 19.4 vs. 61.6 ± 19.8; \( p = 0.002 \)), the overall WHO-5 score (13.1 ± 5.9 vs. 14.3 ± 6.0; \( p < 0.001 \)), and the number of patients with WHO-5 scores <13 (54.9 vs. 43.0%; \( p = 0.003 \)) showed significantly reduced HRQoL in elderly patients in comparison to nonelderly IPF. Breathlessness was more commonly reported by elderly patients (mean ± SD UCSD-SOBQ 52.6 ± 31.2 vs. 45.5 ± 31.2; \( p = 0.030 \)). The overall assessment of current health status as well as the overall SGRQ and its subdomains symptoms, activity and impacts did not show significant differences between elderly and nonelderly patients.

**TABLE 2 | Comorbidities and number of comorbidities in elderly and nonelderly patients with IPF.**

| Comorbidities                  | Age group <75 years | Age group ≥75 years | p-value |

**Antifibrotic Therapy**

At baseline, 55.4% (n = 194) of elderly patients and 56.8% (n = 374) of nonelderly patients were on antifibrotic therapy, with more elderly patients on nintedanib (23.4 vs. 18.1%; \( p = 0.042 \)) but more nonelderly patients treated with pirfenidone.
(32.0 vs. 38.9%; \( p = 0.032 \); see Table 3). Of the 568 patients with antifibrotic therapy at baseline, 20.1% elderly and 20.9% nonelderly patients discontinued antifibrotic therapy during the follow-up (\( p = 0.868 \)). While significantly more elderly had to discontinue antifibrotic therapy due to lack of tolerability (79.5 vs. 52.6%; \( p = 0.019 \)), reasons for discontinuation of antifibrotic therapy were less often due to efficacy failure (15.4 vs. 34.6%) and other reasons (5.1 vs. 12.8%) compared to nonelderly patients. Dose distribution of pirfenidone and nintedanib did also not differ significantly between elderly and nonelderly IPF.

FVC, forced vital capacity; 6MWD, 6 minutes walking distance; IPF, idiopathic pulmonary fibrosis.

Pirfenidone was taken in full dose (2,403 mg/day) by 61.7% of elderly patients who took pirfenidone and 67.2% of nonelderly patients (\( p = 0.352 \)) who took pirfenidone. The full dose 300 mg/day nintedanib were taken by 80.5% elderly patients who took nintedanib and 83.5% nonelderly patients (\( p = 0.537 \)) who took nintedanib.

Follow-up data after initiation of antifibrotic therapy was available in 148 elderly (42.3%) and 294 nonelderly (44.6%) patients. In elderly patients, FVC% pred. was significantly higher in comparison to nonelderly patients at the time of initiation of antifibrotic therapy [71.7% (95% CI: 68.1–75.2) vs. 66.5 (95% CI: 64.1–68.9) \( p = 0.002 \)]. Using a model analyzing FVC decline after initiation of antifibrotic therapy in patients with IPF, on average, there was no significant difference between age groups at any time point over 24 months (beta: 0.41; 95%-CI: −0.98 to 1.81; \( p = 0.563 \); Table 5 and Figure 1). Additionally, over the course of time, there was no significant difference between elderly and nonelderly patients (beta: −0.05; 95%-CI: −0.20 to 0.09; \( p = 0.478 \); Table 5). Other associations between FVC decline under antifibrotic therapy and different clinical variables are shown in detail in Table 5.

**Survival**

In elderly IPF patients, the mean ± SD follow-up was 1.9 ± 1.3 years (median 1.5; IQR: 0.7–3.0) and in nonelderly patients 2.3 ± 1.4 years (median 2.1; IQR: 1.0–4.0). During the follow-up, 172 (49.1%) elderly and 250 (37.9%) nonelderly patients died. Reasons for death are shown in detail in Table 6. The all-cause mortality was higher in elderly IPF (49.1 vs. 37.9%; HR 1.65; 95%-CI 1.36–2.00; \( p < 0.001 \); Figure 2). While all other reasons for death did not show significant differences between elderly

![FIGURE 1](image-url) | Longitudinal course of FVC (% pred.). FVC decline is shown in elderly (gray line, \( n = 148 \)) and nonelderly (black line, \( n = 294 \)) patients with IPF. Differences were not statistically significant. FVC, forced vital capacity; IPF, idiopathic pulmonary fibrosis.
and nonelderly IPF, more elderly patients died due to unknown reasons for death (26.0% vs. 15.0%; HR 2.23; 95%-CI: 1.68–2.96; p < 0.001). During the follow-up one (0.3%) elderly patients with IPF and three (0.5%) nonelderly patients died due to lung cancer (0.90; 95%-CI: 0.11–7.66; p = 0.926).

For the mortality analysis, patients who underwent lung transplantation were censored at the time of lung transplantation [elderly: n = 0 (0.0%); nonelderly: n = 42 (6.4)]. Choosing a combined endpoint of all-cause mortality and lung transplantation also resulted in a higher transplant-free mortality in elderly IPF (49.1 vs. 42.9%; HR 1.47; 95%-CI 1.22–1.78; p < 0.001).

Multivariable analysis for all-cause mortality identified the age group ≥75 years (HR 1.49; 95%-CI: 1.20–1.85; p < 0.001), FVC

IPF, idiopathic pulmonary fibrosis; BMI, body mass index; FVC, forced vital capacity; GAP, gender-age-physiology index; HRCT, high resolution computed tomography; NYHA, New York Heart Association.

(0.98; 95%-CI: 0.98–0.99; p < 0.001), GAP stage II (HR 1.91; 95%-CI: 1.34–2.74; p < 0.001) and III (HR 1.76; 95%-CI: 1.22–2.55; p < 0.001), the categorization into slow (HR 1.38; 95%-CI: 1.08–1.76; p = 0.009) and rapid progressive (HR 1.76; 95%-CI: 1.22–2.55; p = 0.002) and no antifibrotic therapy (HR 1.35; 95%-CI: 1.10–1.65; p < 0.01) as being significant predictors for mortality in the whole study population (Table 7). Antifibrotic therapy was associated with a significantly better survival independent from age groups (<75 years: beta 0.76; 95%-CI: 0.59–0.99; p = 0.049; ≥75 years: beta 0.71; 95%-CI: 0.51–0.98; p = 0.043).

When only considering elderly patients, in contrast to the entire cohort, GAP stage II and III were no significant predictors but the duration since first IPF symptoms (HR 0.92; 95%-CI 0.91–0.99; 0.009). Analyzing only nonelderly patients, slow progression and rapid progression were no significant predictors for mortality.

### DISCUSSION

Under clinical practice conditions, derived from our data from the INSIGHTS IPF registry, over one third of IPF patients are 75 years or older at registry enrollment. Our study identified marked clinical differences between elderly patients and nonelderly patients with IPF including a higher number of comorbidities and reduced HRQoL. At baseline, patients received equally often antifibrotic therapy without differences in the effectiveness of therapy among age groups. All-cause mortality and unknown reasons for death were more often seen in elderly IPF. Antifibrotic therapy was a significant predictor for a better survival in both elderly and nonelderly patients.

Although our study showed that a significant number of patients with IPF are 75 years or older, data about this patient group and its clinical characterization are sparse. It is known that pulmonary function and oxygenation are declining with aging (17). While our elderly patients with IPF had a better FVC and FEV1 at baseline, the gas exchange and oxygenation were more impaired in comparison to nonelderly patients. This is in contrast to a study with a smaller sample size which identified no differences in lung function, gas exchange and oxygenation between patients with IPF ≥70 years and <70 years (18). Interestingly, duration since first IPF symptoms was shorter in elderly patients. Possible explanations are that, on the one hand, elderly patients have more comorbidities, which might lead to more frequent physician consultations with subsequent medical work-up and diagnosis of lung disease. On the other hand, time to diagnosis might be longer in nonelderly patients since differential diagnosis are more likely and diagnostic work-up is more thorough compared to elderly patients. Most likely due to risk assessment, less elderly patients underwent surgical lung biopsy and the diagnosis of IPF was more often based on HRCT in elderly patients. In our study, the number of comorbidities was higher in elderly IPF, mostly driven by a higher prevalence of cardio-vascular diseases such as left heart disease, coronary artery disease, peripheral arterial disease, atrial fibrillation and arterial hypertension. IPF is known to be associated with various cardiac comorbidities (6, 19, 20). Further, all of the comorbidities we identified are known to be more prevalent in an aging population (21, 22). The prevalence of cardiovascular comorbidities (i.e., coronary artery disease and arterial hypertension) was not only high in elderly, but also in nonelderly patients with IPF. It has been shown before, that arterial hypertension can be found in 14–71% of patients with IPF (6). The prevalence of coronary artery disease was reported to range between 4 and 68% in patients with IPF (6), with higher numbers in studies including patients on the waiting list for...
transplantation (23). The majority of patients in the INSIGHTS IPF registry have a history of smoking (10). Given the association between smoking and cardiovascular disease (24), this might partially explain the higher prevalence of coronary artery disease and arterial hypertension. There is also data showing that there is an association between patients with pulmonary fibrosis and coronary artery disease (25). Depression and anxiety are also frequently observed in patients with IPF, as patients with chronic lung disease are prone to psychological distress. In patients with ILD, depression and anxiety were found to be present in up to 23–49% and in 31%, respectively (26, 27). While in these studies with a smaller sample size, depression was independent from age, we found depression and anxiety to be less present in elderly IPF (26, 27). Perhaps elderly patients can cope better with the diagnosis of a fatal disease than nonelderly patients. Hence, comorbidities have to be acknowledged individually in the management of elderly patients with IPF. Overall, HRQoL was more reduced in elderly patients. The SGRQ, which was originally designed for COPD, showed no differences between age groups, which is in line with another study which identified the SGRQ independent from age in IPF (28). However, it must be noted that the EQ-5D and the WHO-5 used in our study are not IPF- or ILD-specific questionnaires. Still, we have shown recently in patients from the INSIGHTS IPF registry, that EQ-5D VAS and WHO-5 are associated with IPF disease progression as both parameters decrease significantly over time indicating a worsening HRQoL and patients with a decrease of >10% FVC over time have lower EQ-5D scores in the follow-up (14). Further, associations were seen between lower EQ-5D VAS and WHO-5 scores and mortality and also hospitalization (14).

A major focus of our study was antifibrotic therapy in an elderly IPF cohort. Recently, an US registry study identified age being negatively associated with antifibrotic therapy use (pirfenidone and nintedanib) (29). In contrast, in our study, more than half of elderly and nonelderly patients were treated with antifibrotic therapy at the time of enrollment, with no differences in age groups. Of note, there were significant differences concerning the drug distribution between age groups: while pirfenidone was more often used in nonelderly, nintedanib was more common in elderly IPF which might be explained by different side effect profiles and tolerability of the individual drugs. Recently, it has been shown that over 1 year follow up patients with IPF ≥75 years are more likely to discontinue pirfenidone and have a higher incidence of gastrointestinal disorders (30). In our study, dose reduction and discontinuation of therapy occurred equally often in both age groups. Lack of tolerability was more often a reason for discontinuation in elderly patients, while nonelderly discontinued more often due to efficacy failure or other reasons. Further, in our study, the course of FVC under antifibrotic therapy was independent from age groups, which is in line with data from a subgroup analysis of the two INPULSIS trials (nintedanib vs. placebo) (8). Taken together, this points out that the two antifibrotic therapies, which are currently the only approved medical treatment option in IPF (31), are effective in elderly patients and IPF patients shall therefore be treated with an antifibrotic therapy (32), regardless of the patients’ age.

Another finding of our study was that all-cause mortality and death with unknown reasons were higher among elderly patients. This is in line with previous findings, where age has been identified as risk factor for mortality in IPF (12, 33). Interestingly, death related to IPF was not increased in elderly patients. In the present study, we identified several risk factors for early death in the entire cohort including the age group ≥75 years and no antifibrotic therapy. In 2018, data from the European IPF registry (eurIPFreg) suggested that patients with IPF and antifibrotic therapy have a better survival in comparison to patients without antifibrotic therapy (34). Recently, a positive effect of antifibrotic therapy on all-cause mortality was also identified using a large U.S. insurance data base without differences between pirfenidone and nintedanib (35). In line with these results, we also described a significantly better survival in IPF patients with antifibrotic therapy in the here analyzed INSIGHTS-IPF registry (16). In the present analysis of INSIGHTS-IPF, which is based on a considerably larger cohort and a longer follow-up, we could show that in elderly and nonelderly patients, antifibrotic therapy was significantly associated with better survival, which underlies again the benefit of antifibrotic therapy in patients with IPF independent from age. Beyond common predictors of mortality, there were also differences between the age groups. For example, duration since first IPF symptoms was a predictor for mortality, which was only identified in the elderly age group, but neither in the entire nor in the nonelderly age group. Further, slow and rapid progressions were significant predictors in elderly patients with IPF but not in nonelderly which underlines the importance of clinical assessment in the prognosis of disease in elderly patients. Interestingly, GAP stages II and III were no predictors for survival in elderly patients with IPF. This could be potentially caused by the fact, that all patients were ≥75 years, which qualifies every patient for the maximum of points in the “age” domain and leaves less discrimination (12). But more studies are needed to evaluate the usefulness of the GAP index in elderly patients.

Our study has strengths and limitations. The main strength is the large cohort of eligible patients; further strengths are the real-world setting, the prospective and multicentre data acquisition, and the comparatively long follow-up period. As limitations, first, owing to the (non-interventional) study time, the data collection varies in different study sites including documented visits and visit time-points depending on clinical routine schedules. Second, data were collected in highly experiences sites (possible selection bias). Third, transplantation was not included in the survival analysis since none of the elderly patients would have qualified for this intervention. Another limitation might be, that less elderly patients underwent surgical lung biopsy and the histological confirmation of a UIP pattern would strengthen the diagnostic confidence of IPF. However, over two thirds of elderly (and nonelderly) patients without surgical lung biopsy had UIP pattern on the HRCT scan. According to the guidelines, in patients with newly detected ILD with clinically suspected IPF and a HRCT pattern of UIP surgical lung biopsies is not essential (1, 36). In addition, the diagnosis of IPF was based on a multidisciplinary discussion in the majority of elderly and nonelderly patients, respectively. Further, a significant
amount of data is missing in this retrospective analysis. The incompleteness of data especially affected the evaluation of HRQoL questionnaires, which were not available for all patients and the lung function over time under antifibrotic therapy. We could only include a limited number of patients in the longitudinal analysis of antifibrotic therapy effects, as we only included patients in whom an antifibrotic therapy was newly initiated and a sufficient follow-up was present. Further, we only included patients in this analysis if the antifibrotic therapy was started not earlier than 20 days before and not later than 20 days after a specific study visit, as described before (16). Using 20 days, it can be assumed that the FVC value will not be too strongly influenced by the onset of the therapeutic effect after the start of therapy. Choosing only 15 days as inclusion criteria would have clearly reduced the number of cases resulting in less robust results. Nevertheless, to our knowledge, this is the first study analyzing antifibrotic therapy in elderly patients longitudinally. The analyses were focused on the comparison of elderly and nonelderly patients including the outcomes of antifibrotic therapy. The comparison of patients treated and not treated with antifibrotic therapy was not adjusted by a propensity score. However, the association between antifibrotic treatment and mortality was analyzed in a multivariable Cox regression model including the parameters that were used to estimate the propensity score in Behr et al. resulting in comparable results (16). Concerning HRQoL questionnaires, currently, there are IPF-specific HRQoL questionnaires available such as an adaption of the SGRQ (37) or the Kings’ Brief Interstitial Lung Disease health status (K-BILD) (38), but these were not included in the INSIGHTS-IPF registry. Finally, the cut-off of 75 years may seem arbitrary. Still, similar results in comorbidities, HRQoL, the effects of antifibrotic therapy and survival were seen when using a cut-off of 80 years in our study cohort, but due to a more limited number of patients and less robust data we decided to use the cut-off of 75 years for elderly vs. nonelderly patients. Further, the cut-off of 75 years has been used for the definition of “elderly” patients before (39).

In conclusion, a significant proportion of IPF patients are ≥75 years old and the management of these elderly patients requires consideration of the general health situation of elderly people. This includes more comorbidities, global reduced HRQoL and a higher all-cause mortality in elderly in comparison to nonelderly patients with IPF. The effects of an antifibrotic therapy do not differ between elderly and nonelderly patients with IPF and no antifibrotic therapy is a significant predictor for mortality in both age groups, emphasizing the importance for an early antifibrotic therapy in IPF, independent from age.

DATA AVAILABILITY STATEMENT

The datasets presented in this article are not readily available because the data will only be available upon reasonable request. Requests to access the datasets should be directed to Gabriela Leuschner, gabriela.leuschner@med.uni-muenchen.de.

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Ethics Committee of the Medical faculty, Technical University, Dresden. The patients/participants provided their written informed consent to participate in this study.

AUTHOR CONTRIBUTIONS

GL, JK, JB, and NK analyzed and interpreted the data. MK, DP, AP, JK, HW, and JB were study steering committee members and contributed to the design and/or analysis of the data. All authors were involved in collecting the data, in writing the manuscript, and approved the final manuscript.

FUNDING

This INSIGHTS-IPF study was funded between 2012 and 2019 by Boehringer Ingelheim GmbH, in 2020 by GWT-TUD GmbH. The authors declare that the funders were not involved in the study design, collection, analysis, interpretation of data, the writing of this article or the decision to submit it for publication.

ACKNOWLEDGMENTS

The authors thank the patients for their participation in the registry.
