Abstract
Aging, cancer, and longevity have been linked to intracellular Ca\(^{2+}\) signaling and nociceptive transient receptor potential (TRP) channels. We found that TRP canonical 7 (TRPC7) is a nociceptive mechanoreceptor and that TRPC7 channels specifically mediate the initiation of ultraviolet B (UVB)-induced skin aging and tumor development due to p53 gene family mutations. Within 30 min after UVB irradiation, TRPC7 mediated UVB-induced Ca\(^{2+}\) influx and the subsequent production of reactive oxygen species in skin cells. Notably, this function was unique to TRPC7 and was not observed for other TRP channels. In TRPC7 knockout mice, we did not observe the significant UVB-associated pathology seen in wild-type mice, including epidermal thickening, abnormal keratinocyte differentiation, and DNA damage response activation. knockout mice also had significantly fewer UVB-induced cancerous tumors than did wild-type mice, and UVB-induced p53 gene family mutations were prevented in TRPC7 knockout mice. These results indicate that TRPC7 activity is pivotal in the initiation of UVB-induced skin aging and tumorigenesis and that the reduction in TRPC7 activity suppresses the UVB-induced aging process and tumor development. Our findings support that TRPC7 is a potential tumor initiator gene and that it causes cell aging and genomic instability, followed by a change in the activity of proto-oncogenes and tumor suppressor genes to promote tumorigenesis.

### 1 INTRODUCTION

An association between transient receptor potential (TRP) channels and age-related diseases (e.g., cancer, Alzheimer's disease, cardiovascular disease) has been well documented (Santoni & Farfariello, 2011; Takada, Numata, & Mori, 2013; Yue et al., 2015); however, the specific roles of TRP channels in aging and the development of these diseases remain unclear. In a recent study, capsaicin-sensitive nociceptor TRP vanilloid 1 (TRPV1) channel activity in the peripheral sensory neurons of both mice and nematodes was shown to affect longevity and overall metabolism through Ca²⁺-dependent neuroendocrine regulation, such as the dorsal root ganglion innervation of pancreatic cells (Riera et al., 2014). In addition, TRPV1 knockout mice exhibited pain insensitivity and increased longevity similar to those of naked mole-rats (Buffenstein, 2008; Park et al., 2008; Seluanov et al., 2009), which usually live for an astonishing 28 years. Naked mole-rats distinctly lack TRP pain receptors and are primarily youthful and healthy (Buffenstein, 2008), qualities that are attributable to their characteristic pain insensitivity (Park et al., 2008), cancer resistance (Seluanov et al., 2009), low respiratory rate, flexible glycolytic metabolism, and low production of reactive oxygen species (ROS; Park et al., 2017). A key link between the longevity of TRPV1 knockout mice and that of naked mole-rats is that nerve growth factor does not sensitize TRPV1 channels in naked mole-rats; furthermore, because Ca²⁺ influx is reduced in naked mole-rats, inflammatory heat hyperalgesia is not induced (Omerbasic et al., 2016).

Recently, we showed that TRPC7 is involved in ultraviolet B (UVB)-induced skin aging and diacylglycerol production in the cytoplasmic membrane and that this skin aging could be prevented by attenuating the UVB-induced elevation of intracellular Ca²⁺ concentration ([Ca²⁺]; Hsu et al., 2015). The only other known physiologic function of TRPC7 reported to date is its role in the initiation of seizure activity (Phelan, Shwe, Abramowitz, Birnbaumer, & Zheng, 2014). Thus, TRPC7 has been implicated in several pathologic processes, but little is known about TRPC7’s specificity of function or the underlying mechanisms. In this study, we sought to comprehensively examine TRPC7 function in the skin. We first characterized TRPC7 as a nociceptive mechanoreceptor; then, we performed a screen in human keratinocytes to determine that, among other TRP channels, TRPC7 is uniquely involved in UVB-induced skin aging. Furthermore, we identified an early time frame of UVB-induced TRPC7 activation and characterized its downstream effects on skin pathology over time, as well as the mechanisms underlying the effects of UVB-induced TRPC7 activation. Importantly, we show for the first time to our knowledge that TRPC7 plays a critical role in all steps of tumorigenesis, starting with the initiation of tumor formation.

**FIGURE 1** Physiologic role of TRPC7 as a nociceptive mechanoreceptor and the specificity of its cellular mechanism to the TRPC family.

(a) Calibrated von Frey filaments were used to assess mechanical hyperalgesia in wild-type (WT, n = 5) and TRPC7⁻/⁻ knockout mice (KO, n = 4). The threshold grams of force that elicited a response in WT and TRPC7⁻/⁻ knockout mice were recorded and averaged. (b) The mean (± SD) thresholds were significantly different between wild-type and TRPC7⁻/⁻ knockout mice. (c) TRPC7 initiated UVB-induced [Ca²⁺] elevation in human primary keratinocytes. The mean (± SD) [Ca²⁺], from 195 keratinocytes with or without UVB irradiation after a 30-min pretreatment with 1 mM EDTA (extracellular Ca²⁺ chelator) or a TRPC inhibitor (50 μM 2-APB, 25 μM SKF96365 [SKF], or 100 μM LaCl₃). (d) UVB irradiation did not affect thapsigargin (TG)-induced store-operated Ca²⁺ mobilization or Ca²⁺ store depletion-induced Ca²⁺ influx in keratinocytes. Intracellular Ca²⁺ responses were measured by using Ca²⁺ imaging after treating keratinocytes with (e) hydrogen peroxide (H₂O₂; mean ± SD, n = 285 cells [f]), (g) 2-aminothoxydiphenyl borate (2-APB; mean ± SD, n = 285 cells [h]), or (i) iulcin (mean ± SD, n = 285 cells [i]). (k) After the application of ATP to activate TRPCs via the phospholipase C (PLC) pathway in Ca²⁺-free balanced salt solution, extracellular CaCl₂ was added. (l) The mean (± SD) area under the [Ca²⁺] response curves from 250 keratinocytes after the addition of extracellular CaCl₂. The duration of application is indicated by thin black bars. 2 | RESULTS

2.1 UVB-induced Ca\(^{2+}\) elevation is due to nociceptive mechanoreceptor TRPC7 in keratinocytes

We first characterized the physiologic role of TRPC7 in the skin by using TRPC7\(^{-/-}\) knockout mice and found that TRPC7 is a novel mechanoreceptor that transduces mechanical pressure into pain signals (Figure 1a, b, and S1). Next, we examined the mechanism underlying the involvement of TRPC7 in skin aging by testing our hypothesis that TRPC7 initiates UVB-induced skin aging via [Ca\(^{2+}\)]\(_i\) elevation. To determine whether TRPC7 is the specific TRP channel involved in UVB-induced [Ca\(^{2+}\)]\(_i\) elevation and the subsequent production of ROS, we performed experiments with known UVB-activated TRP
channel agonists and antagonists (Table S1) in cultured human keratinocytes. UVB-induced [Ca\textsuperscript{2+}] elevation was attenuated by the pretreatment of keratinocytes with 2-aminoethoxydiphenyl borate (2-APB), SKF96365, or LaCl\textsubscript{3}, all of which are TRPC inhibitors (Figure 1c). We then tested the involvement of other TRP channels in the skin (Toth, Ola, Szollosi, & Biro, 2014), including TRPVs, TRP melastatin (TRPMs), or TRP ankyrin 1 (TRPA1). Ca\textsuperscript{2+} influx induced by Ca\textsuperscript{2+} store depletion was not markedly different in the presence or absence of UVB pre-exposure (Figure 1d), indicating that TRPV6 and TRPM2 channels are not involved in UVB-induced [Ca\textsuperscript{2+}] elevation. Similarly, H\textsubscript{2}O\textsubscript{2}-induced [Ca\textsuperscript{2+}], elevation was not significantly different in the presence or absence of UVB pre-exposure, also indicating that TRPM2 channels are not involved in UVB-induced [Ca\textsuperscript{2+}] elevation (Figure 1e,f). Additionally, TRPV1 and TRPV3 did not initiate UVB-induced [Ca\textsuperscript{2+}], elevation because the Ca\textsuperscript{2+} response to 2-APB (an agonist of TRPV1 and TRPV3; Table S1) was inhibited by UVB exposure (Figure 1g,h). Similarly, the Ca\textsuperscript{2+} response to icilin was inhibited after UVB irradiation, indicating that neither TRPM8 nor TRPA1 is involved in UVB-induced [Ca\textsuperscript{2+}] elevation (Figure 1i,j). Together, these results indicate that TRPC channels specifically are important in the initial stages of UVB-induced [Ca\textsuperscript{2+}] elevation. Consistent with this, adenosine triphosphate (ATP)-induced Ca\textsuperscript{2+} mobilization via the phospholipase C pathway resulted in the greatest subsequent influx of extracellular Ca\textsuperscript{2+} after UVB irradiation, and this effect was blocked by the pretreatment of keratinocytes with the TRPC inhibitors 2-APB, SKF96365, or LaCl\textsubscript{3} (Figure 1k,l).

### 2.2 UVB-induced ROS production specifically results from TRPC7-mediated Ca\textsuperscript{2+} influx

We then narrowed down which TRPC(s) in the skin initiate UVB-induced [Ca\textsuperscript{2+}], elevation via the phospholipase C pathway. IP\textsubscript{3} activates TRPC1, TRPC4, and TRPC5 channels, whereas diacylglycerol activates TRPC6 and TRPC7 channels (Harteneck & Leuner, 2014).

No difference was observed in uncaged IP\textsubscript{3}-mediated Ca\textsuperscript{2+} influx in keratinocytes in the presence or absence of UVB pre-exposure (Figure 2a,b). However, UVB pre-exposure induced an increase in Ca\textsuperscript{2+} influx in the presence of the diacylglycerol analogue 1-oleoyl-2-acetyl-sn-glycerol (OAG) (Figure 2c,d), an effect that was inhibited by SKF96365. These results indicate that the channels most likely involved in UVB-induced [Ca\textsuperscript{2+}], elevation are TRPC6 and TRPC7.

UVB-induced [Ca\textsuperscript{2+}], elevation triggers the generation of intracellular ROS (Masaki, Izutsu, Yahagi, & Okano, 2009). We found that UVB-induced [Ca\textsuperscript{2+}], elevation and ROS production began within 30 min after UVB irradiation but were inhibited by TRPC inhibitors in keratinocytes (Figure 2e,f). Furthermore, the knockdown of TRPC7 but not TRPC6 significantly inhibited UVB-induced ROS production in keratinocytes (Figure 2g,h). Moreover, the knockdown of TRPC7 significantly decreased Ca\textsuperscript{2+} influx induced by the diacylglycerol analogue OAG after UVB irradiation (Figure 2i–k). We further showed that TRPC7 was localized to the plasma membrane in keratinocytes (Figure 2i). These results indicate that UVB-induced [Ca\textsuperscript{2+}], elevation results from the influx of extracellular Ca\textsuperscript{2+} and not the mobilization of Ca\textsuperscript{2+} from intracellular stores, and that this specifically occurs through TRPC7 channels.

### 2.3 TRPC7 mediates UVB-induced epidermal pathology in mice

Next, we performed experiments using TRPC7\textsuperscript{-/−} and TRPC7\textsuperscript{+/−} knock-out mice to determine whether UVB-induced [Ca\textsuperscript{2+}], elevation via TRPC7 initiates cell senescence through oxidative stress and activation of the DNA damage response (DDR), leading to epidermal aging. In the absence of UVB, skin phenotype was similar between wild-type and TRPC7\textsuperscript{-/−} or TRPC7\textsuperscript{+/−} mice (Figure S2). In wild-type mice, UVB exposure induced severe desquamation and erythema of the skin. However, in TRPC7\textsuperscript{-/−} and TRPC7\textsuperscript{+/−} mice, UVB exposure induced slight or no damage and less epidermal thickening than in wild-type mice (Figure 3a–e).
Furthermore, in wild-type mice, UVB exposure increased the expression of epidermal differentiation markers KRT10 and KRT14, indicating the abnormal differentiation of keratinocytes; however, this effect was markedly attenuated in TRPC7+/− and TRPC7−/− mice (Figure 3f,g). Ca²⁺ is a known regulator of keratinocyte differentiation (Bikle, Xie, & Tu, 2012), and our results indicate that the abnormal differentiation induced by UVB was initiated by TRPC7-mediated [Ca²⁺]i elevation. After UVB exposure, we observed strong Ki-67 staining in the cytoplasm but not in the nuclei of differentiating keratinocytes (Figure 3h), indicating that UVB may induce cell proliferation (El-Abaseri, Putta, & Hansen, ...
FIGURE 3  Role of ultraviolet B (UVB)-induced [Ca^{2+}] elevation via TRPC7 in initiating epidermal aging, abnormal differentiation, and cell senescence through oxidative stress and DNA damage response activation. (a) A schematic showing the experimental design (wild-type [WT], n = 7; UVB, n = 10; TRPC7^+/−, n = 10 and TRPC7^−/−, n = 11). Mice were exposed to UVB three times weekly. Dorsal skin and tail skin punches or clippings were sectioned for histologic and immunohistochemical analysis. (b) Photographs showing the skin’s appearance. (c) Hematoxylin-and-eosin–stained images of dorsal skin and tail skin. Dotted lines indicate the boundaries of the epidermis. Quantification of the mean (± SD) epidermal thickness in (d) dorsal skin and (e) tail skin. *p < .05; **p < .01; ***p < .001. Differentiating cells were detected by using (f) keratin 10 (KRT10; keratinocytes) and (g) keratin 14 (KRT14; epidermis). (h) Ki-67 expression is shown, indicating proliferating epidermal cells (brown, counterstained with hematoxylin). Activation of the DNA damage response was analyzed by using (i) 8-oxo-2′-deoxyguanosine (8-oxodG) staining and (j) terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining. White arrows indicate cells with DNA damage. (k) Cell senescence was determined by detecting senescence-associated β-galactosidase (SA-β-gal) activity. SA-β-gal activity was reduced in the skin of TRPC7 knockout mice.
2006) followed by abnormal differentiation. The shift from proliferation to differentiation may depend on the accumulation of oxidative DNA damage. Indeed, after UVB exposure, TRPC7+/− and TRPC7−/− mice showed less 8-oxodG and TUNEL staining in the epidermis than did wild-type mice, indicating reduced UVB-induced oxidative DNA damage and fragmentation in these mice (Figure 3i,j). In addition, we observed the cytoplasmic expression of 8-oxodG, which is associated with malignancy (Matosevic et al., 2015), in the dorsal skin of wild-type mice but not TRPC7+/− or TRPC7−/− mice after UVB exposure (Figure 3i). SA-β-gal staining, used to analyze cell senescence, was also lower in the epidermis of TRPC7+/− and TRPC7−/− mice than in that of wild-type mice after UVB exposure (Figure 3k). Together, these results provide evidence of a key role of TRPC7 channels in the physiologic and pathologic consequences of UVB irradiation.

2.4 | TRPC7 mediates UVB-induced epidermal aging in mice

We found that after UVB irradiation, the knockdown of TRPC7 in keratinocytes significantly decreased the percentage of senescent cells, as determined by SA-β-gal staining (Figure 4a–c), and improved the ratio of keratinocyte survival (Figure 4d) when compared with control cells. Furthermore, the knockdown of TRPC7 inhibited UVB-induced p53 expression in keratinocytes (Figure 4e–g), which was corroborated by our observation that the UVB-induced activation of the p53 pathway was reduced in TRPC7+/− and TRPC7−/− mice (Figure 4f). In addition, extracellular Ca²⁺ influx is known to induce cyclooxygenase-2 (COX-2) expression, which increases p53 pathway activation and promotes the aging process (Hsu et al., 2015; Kim et al., 2016). We found that after UVB exposure, the high levels of COX-2 protein expression observed in the epidermis of wild-type mice were decreased to minimal levels in TRPC7+/− and TRPC7−/− mice (Figure 4h).

Although the DDR and cellular senescence are involved in the intermediate stages of the aging process, an imbalance of proliferation and apoptosis together with the accumulation of senescent and apoptotic cells results in cell aging (Cerella, Grandjenette, Dicato, & Diederich, 2016). We found that UVB exposure increased the levels of γH2AX, p16INK4A, and cleaved caspase-3 in the epidermis of wild-type mice, indicating increased senescence and apoptosis. Furthermore, the induction of γH2AX, p16INK4A, and cleaved caspase-3 levels was attenuated in TRPC7+/− and TRPC7−/− mice (Figure 4i–k). These results confirm that UVB-induced epidermal aging is attenuated in TRPC7+/− and TRPC7−/− mice, showing that TRPC7 is necessary for the initial increase in [Ca²⁺], and for activating the cascade of cellular processes that lead to skin aging (Figure 4l).

2.5 | TRPC7 mediates UVB-induced tumor initiation and growth

Aging promotes hyperplastic pathologies, with cancer being one of the most serious (Campisi, 2013). We investigated whether interrupting UVB-induced skin aging via the knockout of TRPC7 reduced UVB-induced skin tumorigenesis in mice. Aging-associated tumorigenesis is dependent on the activation of the senescence-associated secretory phenotype (SASP; Watanabe, Kawamoto, Ohtani, & Hara, 2017). We found that UVB-induced SASP activation was reduced in the epidermis of TRPC7+/− and TRPC7−/− mice (Figure S3). In normal keratinocytes exposed to UVB, the p53 family of proteins is activated, and tissue repair is initiated (Campisi, 2013). Despite repeated UVB irradiation for 10 weeks and epidermal thickening at 1 week, the epidermis in all UVB-exposed mice was repaired and restored to a single layer at the 10th week, resembling nonirradiated skin (Figure S4). Once the repair system no longer provides sufficient recovery from injury, however, the aging process begins to advance in the damaged tissue, and the epidermis thicken. In TRPC7+/− and TRPC7−/− mice, we observed the attenuation of this pathology (Figure S5a–d). At week 29, UVB-irradiated mice were injected with carcinogens, and the prevalence and volume of papilloma and sarcoma tumor began to increase by week 34 in wild-type mice (Figure 5e). Significantly fewer TRPC7+/− and TRPC7−/− mice than wild-type mice developed tumors (Figure 5f), and the tumors that did develop in TRPC7+/− and TRPC7−/− mice were of significantly smaller volume (Figure 5g), although TRPC7 deficiency did not completely eliminate tumor formation. In addition, levels of the differentiation markers KRT10 and KRT14 and senescence marker SA-β-gal were upregulated at the boundary of the tumor in UVB-exposed wild-type mice (Figure 5h–i), suggesting that SASP activation and carcinogen-stimulated tumor formation resulted from cell senescence. We also observed the overexpression of TRPC7 in UVB-exposed skin, especially in papilloma (Figure 5k). Our analysis of the pathologic features of cancer in human tissues also supported the hypothesis that TRPC7 promotes cancer progression by mediating tumor growth (Table S2). Furthermore, TRPC7 was found to be overexpressed in tumor biopsies from patients with non-small cell lung cancer (Figure S5). The overexpression of TRPC7 that we observed in tumors from mouse and humans raises the possibility that TRPC7 promotes tumorigenesis.

2.6 | UVB-induced p53 mutations are prevented in TRPC7 knockout mice

To examine how TRPC7 affects UVB-induced tumorigenesis, we performed whole-exome sequencing in the dorsal skin of mice to characterize genetic mutations. We found that TRPC7+/− and TRPC7−/− mice had the smallest percentage of mutations, despite being exposed to UVB (Figure 6a). Further analysis did not reveal significant differences between groups (Figure 6b), but UVB-exposed TRPC7+/− and TRPC7−/− mice consistently had fewer mutations of each variant type than did UVB-exposed wild-type mice (Figure 6c). Whole-exome sequencing also showed that TRPC7+/− and TRPC7−/− mice had a lower number of mutations than did wild-type mice (Figure 6d). Interestingly, two TRP channel genes (TRPC7 and TRPM4) that were presumably mutated from UVB-induced tumorigenesis exhibited a
greater number of mutations in wild-type mice than in TRPC7−/− or TRPC7+/− mice (Figure 6e). UVB exposure in wild-type mice also induced mutations in p53 family genes and in p53-dependent genes (Figure 6f); in contrast, TRPC7−/− and TRPC7+/− mice had no mutations in p53 and fewer mutations in the genes associated with DNA repair, such as ATR, DNMT3B, and RAD50 (Figure 6f). These results showing that p53 and p53-dependent DNA repair molecules were mutated less frequently after UVB exposure and thus maintained their protective functions against UVB-induced tumorigenesis in TRPC7 knockout mice support our findings that tumor formation was reduced in TRPC7 knockout mice (Figure 5). Together, our data suggest that, in response to UVB, TRPC7 is a primary initiator of epidermal aging and skin tumorigenesis, contributes to mutations in the p53 gene family, and promotes the development of cancerous tumors, indicating a novel role of nociceptive TRPC7 in mediating the aging process and cancer progression.

3 | DISCUSSION

In this study, we show evidence for a role of TRPC7 as a potential tumor initiator gene in UVB-induced epidermal aging and skin tumorigenesis. After UVB irradiation, the increased level of diacylglycerol in the cell membrane immediately activates TRPC7 (Hsu et al., 2015),
and increased Ca\textsuperscript{2+} influx from TRPC7 in turn further upregulates TRPC7 levels (Figure 4e). Several Ca\textsuperscript{2+}-dependent transcription factors, such as nuclear factor (NF)-κB, CAMP response element binding protein, and nuclear factor of activated T cells protein may be involved in controlling TRPC7 upregulation to amplify its activation. Nonetheless, our findings indicate that TRPC7 induces Ca\textsuperscript{2+} influx to produce a snowball effect that triggers several signaling pathways to initiate epidermal ROS production, inflammation, DNA damage, senescence, and cell aging. The function of TRPC7 as a potential tumor initiator gene is supported by our findings that it initiates tumor progression by causing cell aging and genomic instability, followed by a change in the activity of proto-oncogenes and tumor suppressor genes.
We show for the first time to our knowledge that TRPC7 is a nociceptive mechanoreceptor that actively participates in all stages of tumorigenesis. This provides a mechanistic link between TRP channels and their putative roles in cancer metastasis by altering cellular Ca\textsuperscript{2+} homeostasis (Fels, Bulk, Petho, & Schwab, 2018).

**FIGURE 6** TRPC7 knockout reduced the number of gene mutations in ultraviolet B (UVB)-induced tumorigenesis. Whole-exome sequencing was used to analyze the number of mutations in the dorsal skin of UVB-exposed wild-type (WT) and TRPC7 knockout mice (n = 3). Merged data from whole-exome sequencing indicated (a) the number of mutations, (b) the contribution of each variant type, and (c) the number of mutations of each variant type. (d) A heat map illustrates the number of mutations from UVB-induced tumorigenesis, (e) the mutations specific to the TRP gene family, and (f) the p53 family genes and p53-dependent molecules. (g) Schematic representation of the role of TRPC7 as a potential tumor initiator gene in ultraviolet B (UVB)-induced aging and cancer progression. UVB-activated TRPC7 initiates UVB-induced skin aging via intracellular Ca\textsuperscript{2+} elevation, resulting in oxidative stress, DNA damage response (DDR) activation, abnormal differentiation, and senescence inflammation response (SIR) activation; this pathology is repaired with the activation of p53 to maintain tissue homeostasis. When homeostasis is no longer maintained and the aging process is activated, carcinogens promote cancer progression. TRPC7 initiates tumorigenesis by causing genomic instability, thereby changing the activity of proto-oncogenes and tumor suppressor genes. TRPC7 is also overexpressed in cancer progression, which may promote the cell cycle and cytoskeletal remodeling by increasing Ca\textsuperscript{2+} signaling.
According to the theory of tumorigenesis, the DDR triggers the senescence inflammation response (SIR) and SASP activation, and genomic instability results in the activation of oncogenes and the dysfunction of tumor suppressor genes (Pribluda et al., 2013). SIR-induced p53 gene family activation drives the DNA repair system to recover from genomic instability and maintain tissue homeostasis; however, the dysfunction of p53 family genes (or tumor suppressor genes) that results from genomic instability can promote tumorigenesis (Eischen, 2016). Treatment with nonsteroidal anti-inflammatory drugs as tumor preventive agents restrains tumorigenesis by blocking inflammation (Gurpinar, Grizzle, & Piazza, 2014). Although the activation of p53 family genes drives tissue homeostasis, the repeated oncogenic stress from UVB irradiation breaks the balance between genomic instability and the DNA repair system (Pribluda et al., 2013), and Ca\(^{2+}\) signals from UVB-activated TRPC7 initiate tumorigenesis through genomic instability. Furthermore, senescence stimulates tumor formation via SASP activation (Figure 6g). Tumorigenesis, however, is a complex process, and several other tumor initiator genes may be involved in regulating UVB-induced tumor development. Although the blockage of TRPC7 inhibits tumor initiation, it cannot completely prohibit tumor formation.

Our discovery that TRPC7 is a nociceptive mechanoreceptor, together with our previous finding that TRPC7 has a role in UVB-induced skin aging via increased ROS production (Hsu et al., 2015), is consistent with the previously reported links between nociceptive TRP receptors and aging (Buffenstein, 2008; Park et al., 2008; Riera et al., 2014; Seluanov et al., 2009). Interestingly, TRP channel expression has been previously shown to increase with age-related degeneration (Santoni & Farfariello, 2011; Takada et al., 2013; Yue et al., 2015), but our results suggest that TRP channels, especially nociceptive TRP channels, are also important in initiating the aging process. Nociceptive TRP channels respond to environmental stimuli, such as pain, cold, or heat (Venkatachalam & Montell, 2007). The process of aging and age-associated diseases may be due to excess Ca\(^{2+}\) signaling from active nociceptors upon continual environmental stimuli. Interestingly, we found that 55.8% of gene mutations occurred through the natural process of skin aging, but only UVB treatment facilitated the induction of tumorigenesis (Figure 6a). This supports that mutations occur during the natural process of skin aging but that an external trigger such as UVB is required for aging-associated diseases. According to our study, environmental stimulus with UVB activates TRPC7, which is pivotal to the initiation of tumorigenesis associated with skin aging. The possibility remains that aging and aging-associated diseases are caused by the same source of active nociceptors. Blockage of nociceptor activation represents a new strategy for maintaining healthy longevity.

Increased Ca\(^{2+}\) influx may result in genomic instability; however, how alternative Ca\(^{2+}\) homeostasis directly induces tumorigenesis remains unclear. Although cellular senescence depends on the arrest of cell proliferation, we speculate that Ca\(^{2+}\) influx via TRPC7 simultaneously activates Ca\(^{2+}\)-activated K\(^+\) channels to reduce the intracellular K\(^+\) concentration, which activates cell proliferation (Kunzelmann, 2005; Lehenkari, Shapovalov, Skryma, & Prevarskaya, 2011). Thus, TRP channel upregulation potentially maintains cell proliferation, giving way to tumorigenesis. TRPC7 channels may maintain cell proliferation to a greater extent than previously believed because they have a large permeability ratio \([p(Ca^{2+}/Na^+) = 0.7–5.0]\) and sufficient conductance (25–50 pS; Gees,Colsoul, & Nilius, 2010; Owsianik, Talavera, Voets, & Nilius, 2006). Thus, the activation of TRPC7 may have a greater, more immediate effect on Ca\(^{2+}\) entry than does the activation of other TRP channels. If Ca\(^{2+}\) entry from TRPC7 is important to maintain tumorigenesis, malignant cells potentiate intensive epigenetic regulation and mutation according to the evolution of a tumor (Coyle, Boudreau, & Marcato, 2017). In our study, we found that TRPC7 upregulation in tumors promotes tumor growth and also maintains genomic instability. Additionally, in TRPC7 knockout mice, p53 was protected from mutations because of the disruption of cell senescence. These results suggest that the expression of mutated p53 may be mediated through epigenetic regulation by UVB-activated TRPC7. Epigenetic reactivation of tumor suppressor genes can be determined by Ca\(^{2+}\) signaling, and targeting epigenetic pathways is a potential approach for cancer therapy (Raynal et al., 2016). Therefore, it is conceivable that, after the UVB-induced mutation of p53, the expression of mutated p53 is suppressed epigenetically, and the TRPC7-mediated epigenetic reactivation of mutated p53 in turn promotes tumorigenesis.

In conclusion, we examined the mechanism underlying cancer resistance and longevity resulting from reduced nociceptive TRP channel expression (Riera et al., 2014). Although nociceptive TRP channels transduce stimulation into neuronal impulses for perception, they are also “first responders,” with an influx of Ca\(^{2+}\) to protect tissue against harm from extreme mechanical pressure, temperature, or irradiation. Consistent with this first responder role of TRP channels, our results show that harmful UVB exposure induces Ca\(^{2+}\) influx through nociceptive TRPC7 channels. TRPC7 activation, however, also initiates skin aging, results in mutations in the p53 gene family, and promotes the development of cancerous tumors. Indeed, our findings suggest that TRPC7 is a potential tumor initiator gene in tumorigenesis. Finally, our results may explain why the blocking or lack of nociceptive TRP channels facilitates pain relief, cancer resistance, and longevity.

### MATERIALS AND METHODS

#### 4.1 | Chemicals

Thapsigargin (TG), 2-aminoethoxydiphenyl borate (2-APB), H\(_2\)O\(_2\), iberin, ATP, 1-oleoyl-2-acetyl-sn-glycerol (OAG), SKF96365, LaCl\(_3\), ethylendiaminetetraacetic acid (EDTA), dihydroethidium (DHE), phorbol myristate acetate (PMA), 7,12-dimethylbenzanthracene (DMBA), and all other reagents were purchased from Sigma-Aldrich. Fluo-4-AM and caged IP\(_3\) were purchased from Thermo Fisher Scientific. 
4.2 | Cell culture

Human primary keratinocytes were purchased from Lonza. Keratinocytes were incubated at 37°C in humidified 5% CO,
serum-free keratinocyte growth medium supplemented with human recombinant epidermal growth factor, bovine pituitary extract (5 μg/ml each), human insulin-like growth factor I (1 μg/ml), and hydrocortisone (5 μg/ml; Gibco BRL).

4.3 | Calcium imaging

To examine which TRP channels were involved in UBV-induced Ca\(^{2+}\) elevation, intracellular Ca\(^{2+}\) responses in human keratinocytes were induced by pretreatment with 20 nM TG, 2 μM 2-APB, 100 μM H\(_2\)O\(_2\), 100 μM Icili, 200 μM ATP, or 100 μM OAG combined with each TRP channel’s inhibitor before UBV irradiation, as previously described (Hsu et al., 2015). Before the experiments, cells were loaded with 1 μM Fluo-4-AM (Molecular Probes) at 37°C for 20 min and then washed with balanced salt solution buffer (5.4 mM KCl, 5.5 mM D-glucose, 1 mM MgSO\(_4\), 130 mM NaCl, 20 mM HEPES [pH 7.4], and 2 mM CaCl\(_2\)). Intracellular Ca\(^{2+}\) concentrations ([Ca\(^{2+}\)]\(_i\)) were calculated from the ratio of fluorescence intensities (in the absence of Ca\(^{2+}\)) and that were emitted at 509 nm upon excitation with consecutive 3-s pulses of 488-nm light at a resolution of 1,376 × 1,038 pixels by using an Olympus Cell^R IX81 fluorescence microscope (Olympus) equipped with an MT 20 illumination system (Olympus) and UPlanApo 10× objective lens. [Ca\(^{2+}\)]\(_i\) was calculated by using Fluo-4 excited at 488 nm and imaged at 20°C by using the same instrument. To calibrate the measurements, the fluorescence intensity from microcuvettes containing 10 mM K\(_2\)-EGTA (pH 7.2) buffered to various Ca\(^{2+}\) concentrations. [Ca\(^{2+}\)] was calculated by using the following formula: [Ca\(^{2+}\)]\(_i\) = K\(_d\) \((F - F_{\text{min}}) / (F_{\text{max}} - F)\), where K\(_d\) = 345 nM, F = Fluo-4 intensity, F\(_{\text{max}}\) = 640, and F\(_{\text{min}}\) = 21.7 for Fluo-4.

4.4 | Focal IP\(_3\) uncaging

Caged IP\(_3\) was uncaged by using photolysis with UV light (300-400 nm) to investigate the activation of TRPC1, TRPC4, and TRPC5. For photolytic uncaging, an Olympus FV1000 MPE multiphoton laser scanning microscope equipped with an argon laser was used to produce a collimated light beam as the principal uncaging laser line at λ = 408 nm. To detect the effect of IP\(_3\) on TRPC Ca\(^{2+}\) responses, keratinocytes were plated on 2.4-mm coverslips in a 4-cm dish. After 50 mg/cm\(^2\) UVB irradiation, cells were pretreated with 2 μM caged IP\(_3\) for 30 min and stained with the Ca\(^{2+}\) dye Fluo-4 to analyze changes in intracellular Ca\(^{2+}\) levels. Ca\(^{2+}\)-induced fluorescence was observed using an Olympus FV1000 laser scanning microscope. Caged IP\(_3\) was uncaged via illumination with UV light (λ = 408 nm), and IP\(_3\) molecule released was immediately available to bind IP\(_3\) receptors and TRPCs.

4.5 | Intracellular ROS measurement

Cells were stained with 5 μM dihydroethidium (free radical indicator), and the intensity of emitted fluorescence was analyzed by using an Olympus FV1000 laser scanning microscope.

4.6 | Quantitative reverse transcription–polymerase chain reaction (qRT-PCR)

After transfection with each siRNA (control siRNA, siTRPC1, siTRPC4, siTRPC5, siTRPC6, and siTRPC7) for 24 hr, total RNA was extracted from keratinocytes by using TRIzol reagent (Thermo Fisher Scientific). Complementary DNA was synthesized from RNA (1 μg) by using a reverse transcriptase kit (Thermo Fisher Scientific). Incubation conditions included 10 min at 25°C, 120 min at 37°C, and 5 min at 85°C. The resulting complementary DNAs were used to detect the expression of each TRPC gene in skin (TRPC1, TRPC4, TRPC5, TRPC6, and TRPC7) by performing quantitative PCR with a TaqMan Gene Expression Assay kit (Thermo Fisher Scientific).

4.7 | TRPC7 knockout mice and UVB treatment protocol

TRPC7 knockout mice were purchased as heterozygous TRPC7+/- mice (TRPC7tm1.1Lbi/Mmjax) from Mutant Mouse Resource and Research Center (MMRRC). Our TRPC7+/-, TRPC7+/−, and TRPC7+/- mouse colonies were housed at the National Laboratory Animal Center (NLAC), and animal experiments were performed at Kaohsiung Medical University in Taiwan. To examine skin pathology after UVB exposure, 8-week-old mice were exposed to 360 mJ/cm\(^2\) UVB (radiation 280-320 nm) three times weekly, and skin aging and tumor development were monitored. All animal experiments were performed under an affidavit of approval of animal use protocol at Kaohsiung Medical University (IACUC approval number 103122).

4.8 | Immunohistochemistry staining of skin tissue

Dorsal and tail skin from TRPC7+/-, TRPC7+/−, and TRPC7+/- mice were fixed and embedded in paraffin. Antibodies against Ki-67 (proliferation marker; Abcam), COX-2 (cyclooxygenase-2; Abcam), P16INK4A (senescence marker; Sigma-Aldrich), caspase-3 (activated form, apoptosis mediator; GeneTex), interleukin-6 (IL-6; GeneTex), tumor necrosis factor alpha (TNF-α; GeneTex), or regulated upon activation normal T cell express sequence (RANTES, also known as CCL5; GeneTex) were used to detect target molecules. Immunoreactivity
was visualized after incubation with 3,3’-diaminobenzidine (DAB) substrate-chromogen solution (DAKO) according to the manufacturer’s protocol.

4.9 | Immunofluorescence staining

Fixed keratinocytes or paraffin-embedded skin sections were incubated with primary antibodies against TRPC7 (GeneTex), KRT10 (keratin 10; Proteintech), KRT14 (keratin 14; Proteintech), 8-oxodG (8-hydroxy-2’-deoxyguanosine; Abcam), or SA-β-gal (senescence-associated β-galactosidase; Abcam) at 4°C overnight. Cells or skin sections were subsequently incubated with secondary antibody for 1 hr and then with 4’,6-diamidino-2-phenylindole (DAPI, Thermo Fisher Scientific) for 5 min. Tissue was mounted on coverslips that were incubated with primary antibodies against TRPC7 (GeneTex), KRT10, or KRT14 (Proteintech) constructs by using GenMute™ siRNA Transfection Reagent (SignaGen Laboratories). After transfection, healthy, subconfluent keratinocytes were cultured for 48 hr before undergoing further analysis. The expression of target genes was validated by using qRT-PCR or Western blot analysis.

4.10 | Western blot analysis

Western blot analysis was performed with whole-cell lysates. Briefly, cells were lysed by incubation on ice for 30 min in M-PER Mammalian Protein Extraction Reagent (Thermo Fisher Scientific) containing proteinase and phosphatase inhibitors. Cell debris were removed by centrifugation at 10,000 g for 10 min at 4°C. The protein concentration of cell lysates was determined by using the Bradford method (Bio-Rad). Proteins (50 μg) in cell lysates were resolved by performing sodium dodecyl sulfate–polyacrylamide gel electrophoresis in a 10% gel and then transferred to a Hybond-P polyvinylidene fluoride membrane (Amersham Biosciences). The membrane was first incubated with primary antibodies against TRPC7 (GeneTex), p53 (Cell Signaling Technology), phospho-p53 (Abcam), γH2AX (a marker of DNA double-strand breaks; Novus Biologicals), P16INK4A (Sigma-Aldrich), phospho-P16INK4A (Sigma-Aldrich), caspase-3 (activated form; GeneTex), interleukin-1β (IL-1β; GeneTex), IL-6 (GeneTex), TNF-α (GeneTex), gamma interferon-induced protein (IP-10, also known as CXCL10; Novus Biologicals), RANTES (GeneTex), plasminogen activator inhibitor-1 (PAI-1; GeneTex), β-actin (Sigma-Aldrich), α-tubulin (Santa Cruz Biotechnology), or GAPDH (GeneTex) and then with horseradish peroxidase-conjugated secondary antibodies. Immunoreactive proteins were visualized by using enhanced chemiluminescence reagents (Amersham Biosciences).

4.11 | TRPC knockdown in human keratinocytes

For TRPC knockdown experiments, human primary keratinocytes were transfected with siTRPC1, siTRPC4, siTRPC5, siTRPC6, or sicontrol (Santa Cruz) constructs by using GenMute™ siRNA Transfection Reagent (SignaGen Laboratories). After transfection, non-small-cell lung cancer samples from patients with adenocarcinoma and squamous cell carcinoma were collected in accordance with the relevant guidelines and regulations approved by the Institutional Review Board/Ethics Committee (IRB) at Chi Mei Medical Center, Liouying, Tainan, Taiwan (serial no.: 10405-L01). These patient samples were used in research entitled “Role of TRPC7 in cancer progression study.” Informed consent was obtained from each participant. A total of 100 non-small-cell lung cancer samples were collected between May 2016 and June 2017 and were further analyzed by using immunohistochemistry.

4.12 | Mechanical sensitivity

Mechanical sensitivity was analyzed by examining withdrawal thresholds to a series of von Frey filaments (each calibrated to exert 0.008, 0.02, 0.04, 0.07, 0.16, 0.4, 0.6, 1, or 2 g of force) applied to the paw. The smallest force that produced a withdrawal was recorded as the withdrawal threshold. von Frey filaments were applied 10 times to the paw, once every second. Researchers were blinded to the animal’s status during evaluation.

4.13 | Ethics committee approval

Non-small cell lung cancer samples from patients with adenocarcinoma and squamous cell carcinoma were collected in accordance with the relevant guidelines and regulations approved by the Institutional Review Board/Ethics Committee (IRB) at Chi Mei Medical Center, Liouying, Tainan, Taiwan (serial no.: 10405-L01). These patient samples were used in research entitled “Role of TRPC7 in cancer progression study.” Informed consent was obtained from each participant. A total of 100 non-small-cell lung cancer samples were collected between May 2016 and June 2017 and were further analyzed by using immunohistochemistry.

4.14 | Whole-exome sequencing

Genomic DNA was isolated from the dorsal skin of mice from each of the four groups by using Qiagen DNeasy Blood and Tissue Kit (Qiagen). The quality of the isolated DNA was examined by using an Agilent 2100 Bioanalyzer System according to the manufacturer’s protocols (Agilent Technologies). DNA that passed quality control was sheared into fragments ranging from 150 to 200 bp. Ends were repaired by using blunt-ended fragments with 5’-phosphorylated ends. Specific adaptors obtained from Illumina were ligated to the fragments by using adaptor-modified ends. The unligated adapters were removed by using AMPure XP beads, and the purified samples were amplified by using PCR with SureSelect Primer and SureSelect Pre-capture Reverse PCR primers to generate the library for further analysis. After hybridization was performed by using the exome capture library, samples were amplified with indexed tagging primers by using PCR. The quality and quantity of the enriched library were examined by using an Agilent 2100 Bioanalyzer System and real-time PCR. The samples were then sequenced by using an Illumina Hiseq 4000 (Illumina) according to the manufacturer’s standard protocols. A total of five gigabases of DNA base-pair sequences were read, and the coverage of the whole-exome sequencing was approximately 100-fold.
GraphPad Prism was used to generate bar charts; error bars indicated standard deviations unless otherwise noted. Analysis of variance and Student’s t tests were used to compare the differences between groups. In addition, the differences between TRPC7 expression levels, clinical pathology features, and tumor prevalence were compared by using chi-squared tests. A p-value of less than .05 for the difference between groups was considered statistically significant.

ACKNOWLEDGMENTS

We thank the Center for Research Resources and Development at Kaohsiung Medical University for providing use of the confocal microscope and Olympus Cell^R IX81 fluorescence microscope. The authors also thank Nicole Stancel, PhD, ELS(D), of the Texas Heart Institute in Houston, Texas, for manuscript editing. This work was supported by the Slow Aging Program at Kaohsiung Medical University; the "Aim for the Top Universities Grant" (KMU-TP104D04, KMU-TP105D02, TP104D00, TP104D01, TP104D22, TP105D00, TP105D01, TP105D15, TP05G02, and KMUH107-7R66); the “School Cooperation Grant” (DK107002 and DK106001); the “University of Cologne-Kaohsiung Medical University Agency” (SH000151); Chi Mei Medical Center, Liuying (CLFHR10509 and CLFHR10709); the Ministry of Science and Technology of Taiwan (MOST104-2314-B-037-060, 105-2628-B-037-006-MY3, MOST106-2314-B-037-069, MOST106-2321-B-037-003, MOST107-2321-B-037-002, and 107-2320-B-020-002); and the Vascular and Medicinal Research Fund, Texas Heart Institute, USA (#765-64050). This study was also funded in part by Professor Tohru Yoshioka and Professor Glyn-Po Cheng, of Kaohsiung Medical University.

CONFLICT OF INTEREST

J.S.K. is owner of BPS International, which has received consulting fees from Agenda Incorporado, Oncos Sec Medical Incorporated, and Veridex, LLC, a Johnson & Johnson company (not related to this work). All other authors declare no competing interests.

AUTHOR CONTRIBUTIONS

W.L.H., M.H.T., C.H.C., and T.Y. designed the experiments. C.J.Y., W.L.H., Y.Y.H., Y.Y.H., L.C.L., T.F.T., and M.H.T. coordinated and performed all animal experiments and tissue analyses. C.Y.W. and J.L.L. collected samples from patients and assisted with clinical data analysis. W.L.H., J.H.L., and J.L.L. cultured primary keratinocytes and performed the cellular imaging study of Ca\(^{2+}\) dynamics and intracellular reactive oxygen species detection. M.H.T. performed the statistical analysis. C.T.Y. and H.S.Y. provided advice on the project. W.L.H., M.H.T, J.S.K., C.H.C., and T.Y. wrote the manuscript. All authors reviewed and approved the final manuscript.
