The provability logic of all provability predicates

Taishi Kurahashi∗†

Abstract

We prove that the provability logic of all provability predicates is exactly Fitting, Marek, and Truszczynski’s pure logic of necessitation N. Moreover, we introduce three extensions N4, NR, and NR4 of N and investigate the arithmetical semantics of these logics. In fact, we prove that N4, NR, and NR4 are the provability logics of all provability predicates satisfying the third condition D3 of the derivability conditions, all Rosser provability predicates, and all Rosser provability predicates satisfying D3, respectively.

1 Introduction

Let T be a consistent primitive recursively axiomatized LA-theory containing Peano Arithmetic PA, where LA is the language of first-order arithmetic. Gödel’s second incompleteness theorem states that if a provability predicate PrT(x) of T satisfies the following two conditions D2 and D3, then the consistency statement ¬PrT⌜0 = 1⌝ of T cannot be proved in T: for any LA-sentences φ and ψ,

D2: \[ T \vdash Pr_T(⌜φ \rightarrow ψ⌝) \rightarrow (Pr_T(⌜φ⌝) \rightarrow Pr_T(⌜ψ⌝)) \]

D3: \[ T \vdash Pr_T(⌜φ⌝) \rightarrow Pr_T(⌜Pr_T(⌜φ⌝)⌝) \]

In particular, any conventional provability predicate ProvT(x) of T, which naturally expresses that x is the Gödel number of a T-provable formula, satisfies D2 and D3. Therefore, \[ T \not\vdash ¬Prov_T(⌜0 = 1⌝) \] holds.

Every provability predicate PrT(x) is thought of as a kind of modality, and modal logical study of provability predicates has been developed. For each provability predicate PrT(x) of T, the set of all T-verifiable modal formulas under the interpretation where □ is interpreted by PrT is called the provability logic of PrT(x). The most striking result of this study is Solovay’s arithmetical completeness theorem [20] stating that if T is \( \Sigma_1 \)-sound, then the provability logic of ProvT(x) is exactly the Gödel–Löb modal logic GL. There has been a wide

∗Email: kurahashi@people.kobe-u.ac.jp
†Graduate School of System Informatics, Kobe University, 1-1 Rokkodai, Nada, Kobe 657-8501, Japan.
variety of studies on provability logics such as uniform arithmetical completeness theorem, classification of provability logics, quantified provability logics, bimodal and polymodal provability logics, interpretability logics, and so on. See [2, 4, 7, 19] for details of these studies.

On the other hand, not all provability logics are exactly GL. In particular, there exist \( \Sigma_1 \) provability predicates for which the second incompleteness theorem does not hold. A typical example of such a provability predicate is the one that was essentially introduced by Rosser [15]. Let \( \text{Pr}_T^R(x) \) be a Rosser provability predicate of \( T \) saying that there exists a \( T \)-proof \( y \) of \( x \) such that there is no \( T \)-proof of the negation of \( x \) less than \( y \). It is known that \( \neg \text{Pr}_T^R(\neg 0 = 1) \) is provable in \( \mathcal{PA} \). Hence, the provability logic of \( \text{Pr}_T^R(x) \) is completely different from GL because it contains the modal formula \( \neg \square \bot \) that is inconsistent with GL. Also, by the proof of the second incompleteness theorem, \( \text{Pr}_T^R(x) \) does not satisfy at least one of the conditions D2 and D3. And, it has been shown that whether or not \( \text{Pr}_T^R(x) \) satisfies either D2 or D3 depends on the details of construction of \( \text{Pr}_T^R(x) \). In other words, whether the corresponding provability logic contains either \( \square(A \rightarrow B) \rightarrow (\square A \rightarrow \square B) \) or \( \square A \rightarrow \square \square A \) depends on the choice of \( \text{Pr}_T^R(x) \). Indeed, Bernardi and Montagna [3] and Arai [1] proved that there exists a Rosser provability predicate \( \text{Pr}_T^R(x) \) of \( T \) satisfying D2, and hence such a predicate does not satisfy D3. Arai also proved the existence of a Rosser provability predicate satisfying D3. Observe that the provability logics of Rosser provability predicates satisfying D2 contain the normal modal logic KD. The author proved in [11] that there exists a Rosser provability predicate whose provability logic is exactly KD.

Provability predicates that are not \( \Sigma_1 \) whose provability logics are different from GL have also been studied. For example, the author proved in [9] that there exists a \( \Sigma_2 \) provability predicate of \( T \) whose provability logic is exactly the weakest normal modal logic K. Also, for several normal modal logics, the existence of corresponding \( \Sigma_2 \) provability predicates has been shown (cf. [10, 17, 21]).

In previous studies, all unimodal logics that have been considered as provability logics are normal, that is, containing the logic K. Provability predicates corresponding to such logics always satisfy the condition D2. In general, however, not all provability predicates satisfy D2. For example, Rosser provability predicates satisfying D3, whose existence was proved by Arai, do not satisfy D2. The provability logics corresponding to such predicates are non-normal.

In the present paper, we discuss non-normal provability logics through the following questions:

Q1 What is the intersection of all provability logics, that is, the provability logic of all provability predicates?

Q2 What is the provability logic of all Rosser provability predicates?

The property common to all provability predicates is \( T \vdash \varphi \Rightarrow T \vdash \text{Pr}_T(\neg \varphi^\neg) \) that corresponds to the closure under the Necessitation rule \( \frac{A}{\square A} \).
and presumably no other. The non-normal modal logic N, obtained by adding Necessitation $\Box A \vdash A$ as an inference rule to classical propositional logic, was introduced by Fitting, Marek, and Truszczyński [5]. In that paper, N is called the pure logic of necessitation. This logic N is our candidate for the answer to Q1, but a problem arises. The usual proof of Solovay’s theorem is to embed Kripke models into arithmetic, and similar techniques have been used in the proofs of the previously mentioned results for various normal modal logics. On the other hand, since the logic N is not a normal modal logic, N does not have Kripke semantics. However, Fitting, Marek, and Truszczyński introduced a Kripke-like relational semantics corresponding to N, and the soundness, completeness, and finite frame property of N with respect to that semantics were proved. Then, we can attempt to apply Solovay’s method to that semantics. Indeed, in Section 4, we prove that N is exactly the provability logic of all provability predicates. This is the answer to Q1. Moreover, we actually prove more: There exists a $\Sigma_1$ provability predicate of $T$ whose provability logic is exactly N.

Shavrukov [16] introduced the bimodal logic GR of the standard and Rosser provability predicates and proved the arithmetical completeness theorem for GR. Thus, the unimodal fragment $L^R$ of GR is the answer to Q2, but no specific axiomatization of the logic $L^R$ has been made so far. In Section 3, we introduce the logic NR that is obtained from N by adding the inference rule $\neg A \vdash \neg \Box A$. We prove the finite frame property of NR with respect to Fitting, Marek, and Truszczyński’s semantics. In Section 6, we prove that NR precisely coincides with $L^R$ and that NR is exactly the provability logic of all Rosser provability predicates. This is the answer to Q2.

Furthermore, in the present paper, we deal with provability predicates satisfying the condition D3. In Section 5, we also introduce the logics N4 and NR4 that are obtained from N and NR by adding the axiom scheme $\Box A \rightarrow \Box \Box A$, respectively. We prove the finite frame property of N4 and NR4. Also, in Sections 6 and 7 we prove that N4 and NR4 are exactly the provability logics of all provability predicates satisfying D3 and all Rosser provability predicates satisfying D3, respectively.

In Appendix 1, as a related topic, we prove the existence of a $\Sigma_1$ provability predicate whose provability logic is exactly K. In Appendix 2, we prove the interchangeability of $\Box$ and $\Diamond$ in NR. As a continuation of the present paper, in [8], non-normal provability logics closed under the rule $A \rightarrow B \vdash \Box A \rightarrow \Box B$ are investigated.

2 Preliminaries

Let $\mathcal{L}_A$ be the language of first-order arithmetic. Also, let $\omega$ be the set of all natural numbers. We fix a natural Gödel numbering such that if $\psi$ is a proper subformula of $\varphi$, then the Gödel number of $\psi$ is smaller than that of $\varphi$. We may also assume that 0 is not the Gödel number of anything. Let $\{\xi_t\}_{t \in \omega}$ be the repetition-free primitive recursive enumeration of all $\mathcal{L}_A$-formulas arranged
in ascending order of Gödel numbers. That is, if $\xi_s$ is a proper subformula of $\xi_u$, then $s < u$. For each $n \in \omega$, let $\pi$ be the numeral for $n$. We assume that for any natural number $n$ and any formula $\varphi(x)$ having $x$ as a free variable, the Gödel number of $\varphi(\pi)$ is larger than $n$. For each $L_A$-formula $\varphi$, let $\ulcorner \varphi \urcorner$ be the numeral for the Gödel number of $\varphi$. For any two formulas $\varphi$ and $\psi$, $\varphi \equiv \psi$ means that $\varphi$ and $\psi$ are syntactically identical.

Throughout the present paper, $T$ always denotes a consistent primitive recursively axiomatized $L_A$-theory containing Peano Arithmetic $PA$. We say that an $L_A$-formula $\text{Pr}_T(x)$ is a provability predicate of $T$ if for any $L_A$-formula $\varphi$, we have that $T \vdash \varphi$ if and only if $PA \vdash \text{Pr}_T(\ulcorner \varphi \urcorner)$. In his proof of the incompleteness theorems, Gödel constructed a primitive recursive proof predicate $\text{Proof}_T(x, y)$ of $T$ naturally saying that $y$ is the Gödel number of a $T$-proof of an $L_A$-formula whose Gödel number is $x$. The $\Sigma_1$ formula $\text{Proof}_T(x)$ defined by $\exists y \text{Proof}_T(x, y)$ is a standard provability predicate of $T$. Then, it is known that $\text{Proof}_T(x)$ satisfies the conditions $D2$ and $D3$ given in the introduction. We naturally assume that $PA \vdash \forall x \forall y (\text{Proof}_T(x, y) \rightarrow x \leq y)$.

Here, we comment on our definition of provability predicates. We say that a formula $\text{Pr}_T(x)$ satisfies the Kreisel Condition for $T$ if for any $L_A$-formula $\varphi$, $T \vdash \varphi$ if and only if $T \vdash \text{Pr}_T(\ulcorner \varphi \urcorner)$ (cf. Visser [22]). In some cases, it is convenient to define provability predicates of $T$ as formulas satisfying the Kreisel Condition for $T$. However, since the standard provability predicate $\text{Prov}_T(x)$ of $T$ does not generally satisfy the Kreisel Condition for $T$, we prefer to adopt our definition of provability predicates. Moreover, a $\Sigma_1$ formula $\text{Pr}_T(x)$ being a provability predicate of $T$ is equivalent to a natural condition that for any $L_A$-formula $\varphi$, $T \vdash \varphi$ if and only if $\mathbb{N} \models \text{Pr}_T(\ulcorner \varphi \urcorner)$, where $\mathbb{N}$ is the standard model of arithmetic.

We say that a $\Sigma_1$ formula $\text{Pr}_T^R(x)$ is a Rosser provability predicate of $T$ if there exists a primitive recursive formula $\text{Prf}_T(x, y)$ satisfying the following three conditions:

1. For any $L_A$-formula $\varphi$ and $n \in \omega$, $PA \vdash \text{Proof}_T(\ulcorner \varphi \urcorner, n) \leftrightarrow \text{Prf}_T(\ulcorner \varphi \urcorner, n)$.
2. $PA \vdash \forall x (\text{Fml}_{L_A}(x) \rightarrow (\text{Proof}_T(x) \leftrightarrow \exists y \text{Prf}_T(x, y)))$, where $\text{Fml}_{L_A}(x)$ is a primitive recursive formula naturally expressing that $x$ is the Gödel number of an $L_A$-formula.
3. $\text{Prf}_T^R(x)$ is of the form $\exists y (\text{Fml}_{L_A}(x) \land \text{Prf}_T(x, y) \land \forall z < y \neg \text{Prf}_T(\ulcorner \neg(x), z \urcorner))$, where $\ulcorner x \urcorner$ is a primitive recursive term corresponding to a primitive recursive function calculating the Gödel number of $\neg \varphi$ from that of $\varphi$.

It is known that each Rosser provability predicate of $T$ is in fact a $\Sigma_1$ provability predicate of $T$. The idea of witness comparison, which is technically very important, is behind Rosser provability predicates (see [6, 12]). Based on the witness comparison argument, it is shown that for any Rosser provability predicate $\text{Prf}_T^R(x)$ of $T$ and any $L_A$-formula $\varphi$, if $T \vdash \neg \varphi$, then $PA \vdash \neg \text{Prf}_T^R(\ulcorner \varphi \urcorner)$.

The language $L(\square)$ of modal propositional logic consists of propositional variables, the logical constant $\bot$, propositional connectives $\neg, \land, \lor, \rightarrow$, and the modal operator $\square$. Let $MF$ be the set of all $L(\square)$-formulas. The axioms of the
Let $\mathcal{L}(\square)$ be the set of all $\mathcal{L}(\square)$-formulas $A$ satisfying that for any arithmetical interpretation $f$ based on $\Pr_T(x)$ if it satisfies the following conditions:

1. $f(\bot) = 0 = 1$,
2. $f(\neg A)$ is $\neg f(A)$,
3. $f(A \circ B)$ is $f(A) \circ f(B)$ for $\circ \in \{\land, \lor, \to\}$,
4. $f(\square A)$ is $\Pr_T(f(A)\top)$.

Let $\text{PL}(\Pr_T)$ be the set of all $\mathcal{L}(\square)$-formulas $A$ satisfying that for any arithmetical interpretation $f$ based on $\Pr_T(x)$, $T \vdash f(A)$. The set $\text{PL}(\Pr_T)$ is called the provability logic of $\Pr_T(x)$.

It is obvious that for any provability predicate $\Pr_T(x)$ of $T$, $\text{PL}(\Pr_T)$ is closed under $\text{Nec}$. If $\Pr_T(x)$ satisfies $\text{D2}$, then $\text{PL}(\Pr_T)$ contains the logic $K$, that is, $\text{PL}(\Pr_T)$ is a normal modal logic.

The study of provability logics can be approached from two directions corresponding to the following two problems, respectively.

**Problem 2.1.** For each provability predicate $\Pr_T(x)$ of $T$, how is $\text{PL}(\Pr_T)$ axiomatized and what properties does it have?

**Problem 2.2.** For which modal logics $L$ is there a provability predicate $\Pr_T(x)$ such that $L = \text{PL}(\Pr_T)$?

The most striking result concerning the first problem is Solovay’s arithmetical completeness theorem [20]. It states that if $T$ is $\Sigma_1$-sound, then $\text{PL}(\text{Prov}_T)$ is exactly GL. Visser [21] proved that if $T$ is not $\Sigma_1$-sound, then $\text{PL}(\text{Prov}_T)$ is either GL or $\text{GL} + \square^n \perp$ for some $n \geq 1$. As an interesting example regarding the first problem, we present here Shavrukov’s result [17]. Let $\Pr_{PA}^S(x)$ be the $\Sigma_2$ provability predicate $\exists y(\text{Prov}_{1\Sigma_n}(x) \land \neg \text{Prov}_{1\Sigma_n}(\uparrow \text{"0 = 1"}))$ of PA, which was essentially introduced by Smoryński [18]. Shavrukov proved that $\text{PL}(\Pr_{PA}^S)$ is the logic $\text{KD} + (\square A \to \square((\square B \to B) \lor \square A))$.

For the second problem, the following results have been obtained by previous studies.

- (Kurahashi [11]) There exists a Rosser provability predicate $\Pr_T^R(x)$ of $T$ such that $\text{PL}(\Pr_T^R) = \text{KD}$. 

• (Kurahashi [9]) There exists a $\Sigma_2$ provability predicate $Pr_T(x)$ of $T$ such that $PL(Pr_T) = K$.

• (Kurahashi [10]) For each $n \geq 2$, there exists a $\Sigma_2$ provability predicate $Pr_T(x)$ of $T$ such that $PL(Pr_T) = K + (\Box(\Box^n A \rightarrow A) \rightarrow \Box A)$.

• (Montague [14]) For any provability predicate $Pr_T(x)$ of $T$, $PL(Pr_T) \not\subseteq KT$ ($= K + (\Box A \rightarrow A)$).

• (Löb [13]) For any provability predicate $Pr_T(x)$ of $T$, $PL(Pr_T) \not\equiv K_4$.

• (Kurahashi [10]) For any provability predicate $Pr_T(x)$ of $T$, if $T$ does not prove $Pr_T(\langle 0 = 1 \rangle)$, then $PL(Pr_T) \not\subseteq KB$ ($= K + (A \rightarrow \Box \Diamond A)$) and $PL(Pr_T) \not\subseteq K_5$ ($= K + (\Diamond A \rightarrow \Box \Diamond A)$).

All of the above results are for normal modal logics. On the other hand, there is a result concerning a non-normal modal logic. Shavrukov [16] introduced the bimodal logic $GR$ of the standard and Rosser provability predicates. Let $L(\Box, \blacksquare)$ be the language of modal propositional logic equipped with an additional modal operator $\blacksquare$. The axiom schemata of $GR^{-}$ are as follows:

1. Those of $GL$ for $\Box$,
2. $\blacksquare A \rightarrow \Box A$,
3. $\Box A \rightarrow \blacksquare \Box A$,
4. $\Box A \rightarrow (\Box \bot \lor \blacksquare A)$,
5. $\Box \neg A \rightarrow \Box \neg \blacksquare A$.

The inference rules of $GR^{-}$ are MP and Nec for $\Box$. The logic $GR$ is obtained from $GR^{-}$ by adding the rule $\frac{\Box A}{A}$. The studies of $GR^{-}$ and $GR$ presented in [10] were based on those of the logics $R^{-}$ and $R$ developed by Guaspari and Solovay [6]. The logic $GR$ can be embedded into $GR^{-}$ as follows.

**Theorem 2.3** ([16, Corollary 1.10]). For any $L(\Box, \blacksquare)$-formula $A$, $GR \vdash A$ if and only if $GR^{-} \vdash \Box A$.

A bimodal arithmetical interpretation $f$ based on $(Pr_T, Pr_T)$ is an arithmetical interpretation based on $Pr_T(x)$ such that $f(\blacksquare A)$ is $Pr_T^{R}(\langle f(A) \rangle)$. Shavrukov proved the following arithmetical soundness and completeness theorems.

**Theorem 2.4** (The arithmetical soundness theorem of $GR$ [16 Lemma 2.5]). For any Rosser provability predicate $Pr_T(x)$ of $T$, any bimodal arithmetical interpretation $f$ based on $(Prov_T, Pr_T)$, and any $L(\Box, \blacksquare)$-formula $A$, if $GR \vdash A$, then $PA \vdash f(A)$. 

6
Theorem 2.5 (The uniform arithmetical completeness theorem for GR [16 Theorem 3.1]). Suppose that $T$ is $\Sigma_1$-sound. Then, there exist a Rosser provability predicate $Pr^R_T(x)$ of $T$ and a bimodal arithmetical interpretation $f$ based on $(\text{Prov}_T, Pr^R_T)$ such that for any $L(\Box, \square)$-formula $A$, $\text{GR} \vdash A$ if and only if $T \vdash f(A)$.

Let $L^R$ be the unimodal logic obtained by replacing all $\square$ in the $\Box$-free fragment of GR by $\Box$. The following corollary follows from Shavrukov’s theorems.

**Corollary 2.6.** If $T$ is $\Sigma_1$-sound, then

$$L^R = \bigcap \{ \text{PL}(Pr^R_T) \mid Pr^R_T(x) \text{ is a Rosser provability predicate of } T \}.$$  

Furthermore, there exists a Rosser provability predicate $Pr^R_T(x)$ of $T$ such that $L^R = \text{PL}(Pr^R_T)$.

Corollary 2.6 states that $L^R$ is the provability logic of all Rosser provability predicates. The logic $L^R$ is a non-normal modal logic because there are Rosser provability predicates that do not satisfy D2. However, since no specific axiomatization for $L^R$ is obtained, Corollary 2.6 is not sufficient for us in view of Problem 2.1. In this context, our purpose in the present paper is to axiomatize the following four logics:

1. $T \{ \text{PL}(Pr_T) \mid Pr_T(x) \text{ is a provability predicate of } T \}$,
2. $T \{ \text{PL}(Pr_T) \mid Pr_T(x) \text{ is a provability predicate of } T \text{ satisfying D3} \}$,
3. $T \{ \text{PL}(Pr^R_T) \mid Pr^R_T(x) \text{ is a Rosser provability predicate of } T \}$,
4. $T \{ \text{PL}(Pr^R_T) \mid Pr^R_T(x) \text{ is a Rosser provability predicate of } T \text{ satisfying D3} \}$.

In the next section, we introduce the logics $N$, $N4$, $NR$, and $NR4$ which are candidates for axiomatizations of these logics. We study these logics from the point of view of Problems 2.1 and 2.2.

**3 The logic $N$ and its extensions**

For any provability predicate $Pr_T(x)$, the provability logic $\text{PL}(Pr_T)$ is closed under $\text{Nec}$. Thus, the provability logic

$$\bigcap \{ \text{PL}(Pr_T) \mid Pr_T(x) \text{ is a provability predicate of } T \}$$

of all provability predicates is also closed under $\text{Nec}$. On the other hand, there seems to be no other non-trivial modal logical principle that is common to all provability predicates. Our candidate for the axiomatization of the provability logic of all provability predicates is the pure logic of necessitation $N$ that was introduced by Fitting, Marek, and Truszczynski [3]. The axioms of $N$ are propositional tautologies in the language $L(\Box)$ and the inference rules of $N$ are MP and $\text{Nec}$.

Fitting, Marek, and Truszczynski introduced the following natural relational semantics for $N$. 

7
Definition 3.1 (N-frames).

• We say that a tuple \((W, \{\prec B\}_{B \in MF})\) is an \(N\)-frame if \(W\) is a non-empty set and for each \(B \in MF\), \(\prec B\) is a binary relation on \(W\).

• We say that a triple \((W, \{\prec B\}_{B \in MF}, \models)\) is an \(N\)-model if \((W, \{\prec B\}_{B \in MF})\) is an \(N\)-frame and \(\models\) is a satisfaction relation on \(W \times MF\) fulfilling the usual conditions for propositional connectives and

\[ x \models \Box B \iff \forall y \in W (x \prec B y \Rightarrow y \models B). \]

• A formula \(A\) is valid in an \(N\)-model \((W, \{\prec B\}_{B \in MF}, \models)\) if for any \(x \in W\), \(x \models A\).

• A formula \(A\) is valid in an \(N\)-frame \((W, \{\prec B\}_{B \in MF})\) if \(A\) is valid in any \(N\)-model \((W, \{\prec B\}_{B \in MF}, \models)\) based on \((W, \{\prec B\}_{B \in MF})\).

• We say that an \(N\)-frame \((W, \{\prec B\}_{B \in MF})\) is finite if \(W\) is a finite set.

Fitting, Marek, and Truszczyński proved that \(N\) is sound and complete and has the finite frame property with respect to this semantics.

Fact 3.2 (Fitting, Marek, and Truszczyński [5, Theorems 3.6 and 4.10]). For any \(A \in MF\), the following are equivalent:

1. \(N \vdash A\).

2. \(A\) is valid in all \(N\)-frames.

3. \(A\) is valid in all finite \(N\)-frames.

Each \(N\)-model has infinitely many binary relations \(\{\prec B\}_{B \in MF}\), but the truth of each \(L(\Box)\)-formula in each element of the model is determined by referring to only a finite number of those relations. Let \(\text{Sub}(A)\) be the set of all subformulas of \(A \in MF\).

Fact 3.3 (Fitting, Marek, and Truszczyński [5, Theorem 4.11]). Let \(A \in MF\). Let \((W, \{\prec B\}_{B \in MF}, \models)\) and \((W, \{\prec^* B\}_{B \in MF}, \models^*)\) be any \(N\)-models satisfying the following two conditions:

1. For each \(x \in W\) and each propositional variable \(p \in \text{Sub}(A)\), we have that \(x \models p \iff x \models^* p\).

2. For each \(\Box B \in \text{Sub}(A)\), \(\prec B = \prec^*_B\).

Then, for every \(x \in W\), \(x \models A \iff x \models^* A\).

We introduce the three extensions \(NR\), \(N4\), and \(NR4\) of \(N\).

Definition 3.4.

• The logic \(NR\) is obtained from \(N\) by adding the inference rule \(\neg B \vdash \neg \Box B\).
• The logics \( \text{N4} \) and \( \text{NR4} \) are obtained from \( \text{N} \) and \( \text{NR} \), respectively, by adding the axiom scheme \( \Box B \rightarrow \Box \Box B \).

We call the rule \( \frac{\neg B}{\neg \Box B} \) the Rosser rule (Ros). Before proving the completeness theorems for these logics, we show that the validity of these logics is related to some appropriate conditions on \( \text{N} \)-frames.

**Definition 3.5.** Let \( A \in \text{MF} \) and \( \Gamma \subseteq \text{MF} \). Let \( F = (W, \{ \prec_A B \}_{B \in \text{MF}}) \) be any \( \text{N} \)-frame.

- \( F \) is called \( A \)-serial if for every \( x \in W \), there exists a \( y \in W \) such that \( x \prec_A y \).
- \( F \) is said to be \( \Gamma \)-serial if \( F \) is \( A \)-serial for every \( \Box A \in \Gamma \).
- \( F \) is called serial if \( F \) is \( \text{MF} \)-serial.

**Proposition 3.6.** Let \( A \in \text{MF} \) and \( M = (W, \{ \prec_B \}_{B \in \text{MF}}, \models) \) be any \( \text{N} \)-model. Suppose that the \( \text{N} \)-frame \( F = (W, \{ \prec_B \}_{B \in \text{MF}}) \) is \( A \)-serial. If \( \neg A \) is valid in \( M \), then \( \neg \Box A \) is also valid in \( M \).

**Proof.** Suppose that \( F \) is \( A \)-serial and \( \neg A \) is valid in \( M \). Let \( x \in W \) be any element. Since \( F \) is \( A \)-serial, there exists a \( y \in W \) such that \( x \prec_A y \). Since \( \neg A \) is valid in \( M \), we have \( y \models \neg A \). Thus, \( x \models \neg \Box A \). Therefore, \( \neg \Box A \) is valid in \( M \).

**Corollary 3.7.** Let \( A \in \text{MF} \). If \( \text{NR} \models A \), then \( A \) is valid in all serial \( \text{N} \)-frames.

**Definition 3.8.** Let \( A \in \text{MF} \) and \( \Gamma \subseteq \text{MF} \). Let \( F = (W, \{ \prec_B \}_{B \in \text{MF}}) \) be any \( \text{N} \)-frame.

- \( F \) is called \( A \)-transitive if for every \( x, y, z \in W \), if \( x \prec_A \Box y \) and \( y \prec_A \Box z \), then \( x \prec_A \Box z \).
- \( F \) is said to be \( \Gamma \)-transitive if \( F \) is \( A \)-transitive for every \( \Box \Box A \in \Gamma \).
- \( F \) is called transitive if \( F \) is \( \text{MF} \)-transitive.

**Proposition 3.9.** Let \( A \in \text{MF} \) and \( F = (W, \{ \prec_B \}_{B \in \text{MF}}) \) be any \( \text{N} \)-frame. If \( F \) is \( A \)-transitive, then \( \Box A \rightarrow \Box \Box A \) is valid in \( F \).

**Proof.** Suppose that \( F \) is \( A \)-transitive. Let \( (F, \models) \) be any \( \text{N} \)-model based on \( F \). Let \( x \in W \) be any element with \( x \models \Box A \). Let \( y, z \in W \) be such that \( x \prec_{\Box A} y \) and \( y \prec_{\Box A} z \). Since \( F \) is \( A \)-transitive, we have \( x \prec_A z \). Then, \( z \models A \). Since \( z \) is an arbitrary element with \( y \prec_A z \), we have \( y \models \Box A \). Also, we obtain \( x \models \Box \Box A \). We conclude that \( \Box A \rightarrow \Box \Box A \) is valid in \( F \).

**Corollary 3.10.** Let \( A \in \text{MF} \).

1. If \( \text{N4} \models A \), then \( A \) is valid in all transitive \( \text{N} \)-frames.
2. If $\text{NR4} \vdash A$, then $A$ is valid in all transitive and serial $N$-frames.

Unlike the case of Kripke frames, the validity of $\Box A \rightarrow \Box \Box A$ in an $N$-frame is not equivalent to the $A$-transitivity in general.

**Proposition 3.11.** There exists an $N$-frame $F$ satisfying the following conditions:

1. $\Box B \rightarrow \Box \Box B$ is valid in $F$ for all $B \in MF$.

2. For any $B, C_0, \ldots, C_{k-1} \in MF$, if $\text{N} \vdash \Box C_0 \land \cdots \land \Box C_{k-1} \rightarrow B$, then $F$ is not $B$-transitive.

**Proof.** Let $F = (W, \{\prec_B\}_{B \in MF})$ be the $N$-frame defined as follows:

- $W := \{a, b, c\}$,
- If $\text{N} \vdash \Box C_0 \land \cdots \land \Box C_{k-1} \rightarrow B$ for some $k$ and $C_0, \ldots, C_{k-1} \in MF$, then $\prec_B := \{(a, b), (b, c)\}$.
- Otherwise, $\prec_B := \{(a, b), (a, c), (b, c)\}$.

The second clause of the proposition immediately follows from the definition because $a \prec_B b$ and $b \prec_B c$ for each $B \in MF$. It suffices to show that $\Box B \rightarrow \Box \Box B$ is valid in $F$ for all $B \in MF$. Assume that $\text{N} \not\vdash \Box C_0 \land \cdots \land \Box C_{k-1} \rightarrow B$ for any $k$ and $C_0, \ldots, C_{k-1} \in MF$. Then, it is shown that $F$ is $B$-transitive. By Proposition 3.9, $\Box B \rightarrow \Box \Box B$ is valid in $F$.

So, we may assume that $\text{N} \vdash \Box C_0 \land \cdots \land \Box C_{k-1} \rightarrow B$ for some $C_0, \ldots, C_{k-1} \in MF$. In this case, $\prec_B = \{(a, b), (b, c)\}$. Let $(F, \models)$ be any $N$-model based on $F$. For each $C \in MF$, we have $c \models \Box C$ because there is no $w \in W$ such that $c \prec_C w$.

So, we have $c \models \Box B$ and $c \models \Box \Box B$. Moreover, we have $c \models \Box i$ for $i < k$. Then, we obtain $b \models \Box B$ and $b \models \Box \Box B$. Also, we obtain $a \models \Box \Box B$. We conclude that $\Box B \rightarrow \Box \Box B$ is valid in $(F, \models)$.

We prove the completeness and finite frame property of the logics $\text{NR}$, $\text{N4}$, and $\text{NR4}$. I also simultaneously give an alternative proof of Fact 3.2.

**Theorem 3.12** (The completeness and finite frame property of $\text{NR}$). For any $A \in MF$, the following are equivalent:

1. $\text{NR} \vdash A$.

2. $A$ is valid in all serial $N$-frames.

3. $A$ is valid in all finite serial $N$-frames.

4. $A$ is valid in all finite $\text{Sub}(A)$-serial $N$-frames.

**Theorem 3.13** (The completeness and finite frame property of $\text{N4}$). For any $A \in MF$, the following are equivalent:

1. $\text{N4} \vdash A$.
2. A is valid in all transitive N-frames.
3. A is valid in all finite transitive N-frames.
4. A is valid in all finite Sub(A)-transitive N-frames.

Theorem 3.14 (The completeness and finite frame property of NR4). For any \( A \in \text{MF} \), the following are equivalent:

1. \( \text{NR4} \vdash A \).
2. A is valid in all transitive and serial N-frames.
3. A is valid in all finite transitive and serial N-frames.
4. A is valid in all finite Sub(A)-transitive and Sub(A)-serial N-frames.

Proof. We prove Fact \([3.2]\) Theorems \([3.12]\) \([3.13]\) and \([3.14]\) simultaneously. Let \( L \) be one of \( \text{NR}, \text{N4}, \) and \( \text{NR4} \). Assume, however, that the statement (4) is the same as (3) when \( L = \text{N} \).

(1 \( \Rightarrow \) 2): This is already proved in Corollaries \([3.7]\) \([3.10]\).

(2 \( \Rightarrow \) 3): Obvious.

(3 \( \Rightarrow \) 4): Suppose that A is valid in all finite N-frames satisfying the corresponding conditions. Let \( \mathcal{M} = (W, \{\prec_B\}_{B \in \text{MF}}, \mathbb{B}) \) be any finite N-model whose frame \( \mathcal{F} = (W, \{\prec_B\}_{B \in \text{MF}}) \) satisfies the corresponding conditions restricted to Sub(A). For example, if \( L = \text{N4} \), then \( \mathcal{F} \) is Sub(A)-transitive. For each \( B \in \text{MF} \), let \( \prec_B^* \) be the binary relation on \( W \) defined as follows:

\[
\prec_B^* := \begin{cases} 
\prec_B & \text{if } \Box B \in \text{Sub}(A), \\
\{(x, x) \mid x \in W\} & \text{otherwise}.
\end{cases}
\]

Let \( \mathcal{F}^* := (W, \{\prec_B^*\}_{B \in \text{MF}}) \).

Claim 3.15. If \( L \in \{\text{NR, NR4}\} \), then \( \mathcal{F}^* \) is serial.

Proof. Let \( x \in W \) and \( B \in \text{MF} \).

- If \( \Box B \in \text{Sub}(A) \), then there exists a \( y \in W \) such that \( x \prec_B y \) because \( \mathcal{F} \) is Sub(A)-serial. Thus, \( x \prec_B^* y \).
- If \( \Box B \notin \text{Sub}(A) \), then \( x \prec_B^* x \).

We have proved that \( \mathcal{F}^* \) is \( B \)-serial.

\( \square \)

Claim 3.16. If \( L \in \{\text{N4, NR4}\} \), then \( \mathcal{F}^* \) is transitive.

Proof. Let \( x, y, z \in W \) and \( B \in \text{MF} \) be such that \( x \prec_{\Box B} y \) and \( y \prec_B z \).

- If \( \Box \Box B \in \text{Sub}(A) \), then \( \Box B \in \text{Sub}(A) \), and hence \( x \prec_{\Box B} y \) and \( y \prec_B z \). Since \( \mathcal{F} \) is Sub(A)-transitive, we have \( x \prec_B z \). Thus, \( x \prec_B^* B z \).

We have shown that \( \mathcal{F}^* \) is transitive.
Claim 3.17. For any elements of $X$ of $L$ then, $B$ a proof of the case that $W$ is smaller than 2.

We have proved that $F^*$ is $B$-transitive.

Therefore, $F^*$ is a finite $N$-frame satisfying the corresponding conditions. Let $\models^*$ be the satisfaction relation on $F^*$ defined by $x \models^* p : \iff x \models p$. By the supposition, $A$ is valid in $F^*$. In particular, $A$ is valid in $(F^*, \models^*)$. Since $\not\models B$ for any $B \in MF$ with $\Box B \in Sub(A)$, by Fact 3.3 $A$ is also valid in $M$.

(4 $\Rightarrow$ 1): We prove the contrapositive. Suppose $L \not\models A$, and we would like to find a corresponding finite $N$-frame in which $A$ is not valid.

For each formula $B \in MF$, let $\sim B$ be $C$ if $B$ is of the form $\neg C$ and $\neg B$ otherwise. Let $\text{Sub}(A) := \text{Sub}(A) \cup \{\sim B \mid B \in \text{Sub}(A)\}$. We say that $X \subseteq \text{Sub}(A)$ is $L$-consistent if $L \not\models \bigwedge X$ where $\bigwedge X$ is a conjunction of all elements of $X$. Also, $X$ is called $A$-maximally $L$-consistent if $X$ is maximal among $L$-consistent subsets of $\text{Sub}(A)$. It is easily shown that every $L$-consistent subset $X$ of $\text{Sub}(A)$ is extended to an $A$-maximally $L$-consistent set.

We define the $N$-model $M = (W, \{\sim B \}_{B \in MF}, \models)$ as follows:

- $W := \{X \subseteq \text{Sub}(A) \mid X$ is $A$-maximally $L$-consistent$\}$;
- For $X, Y \in W$, $X \prec_B Y : \iff \Box B \not\subseteq X$ or $B \in Y$;
- For each propositional variable $p$ and $X \in W$, $X \models p : \iff p \in X$.

Let $n$ be the number of elements of $\text{Sub}(A)$. We have that the number of elements of $W$ is smaller than $2^n$. Since $L \not\models A$, $\{\sim A\}$ is $L$-consistent. So, we have $X_A \in W$ such that $\sim A \in X_A$.

Claim 3.17. For any $X \in W$ and $B \in \text{Sub}(A)$,

$$x\models B \iff B \in X.$$

Proof. We prove the claim by induction on the construction of $B$. We only give a proof of the case that $B$ is of the form $\Box C$.

($\Rightarrow$): We prove the contrapositive. Suppose $\Box C \not\subseteq X$. Since $X$ is maximal, $\neg \Box C \in X$. Assume, towards a contradiction, that $\{\sim C\}$ is $L$-inconsistent. Then, $L \not\models C$. By NEC, $L \models \Box C$. This contradicts the $L$-consistency of $X$.

We proved that $\{\sim C\}$ is $L$-consistent. Let $Y \in W$ be such that $\{\sim C\} \subseteq Y$. Since $\Box C \not\subseteq X$, we have $X \prec_C Y$ by the definition of $\prec_C$. Since $\sim C \in Y$, we have $C \not\subseteq Y$. By the induction hypothesis, $Y \not\models C$. We conclude that $X \not\models C$.

($\Leftarrow$): Suppose $\Box C \in X$. Let $Y \in W$ be such that $X \prec_C Y$. By the definition of $\prec_C$, we have $C \in Y$. By the induction hypothesis, $Y \models C$. Hence, $X \models \Box C$.

Since $A \not\subseteq X_A$, by Claim 3.17 we obtain $X_A \not\models A$. Therefore, $A$ is not valid in $M$. This completes the proof of Fact 3.2 for $L = N$.

Claim 3.18. If $L \in \{NR, NR4\}$, then $(W, \{\sim B\}_{B \in MF})$ is $\text{Sub}(A)$-serial.
Proof. Let \( X \in W \) and \( \square B \in \text{Sub}(A) \). We distinguish the following two cases:

- Case 1: \( \square B \notin X \).
  By the definition of \( \prec_B \), we have \( X \prec_B X \).

- Case 2: \( \square B \in X \).
  Suppose, towards a contradiction, that \( \{ B \} \) is \( L \)-inconsistent. Then, \( L \vdash \neg B \). By the rule Ros, we have \( L \vdash \neg \square B \). This contradicts the \( L \)-consistency of \( X \). Hence, \( \{ B \} \) is \( L \)-consistent and there exists a \( Y \in W \) such that \( B \in Y \). By the definition of \( \prec_B \), \( X \prec_B Y \).

In either case, we have a \( Y \in W \) such that \( X \prec_B Y \). We conclude that \((W, \{ \prec_B \}_{B \in \text{MF}})\) is \( \text{Sub}(A) \)-serial.

Claim 3.19. If \( L \in \{ N4, \text{NR4} \} \), then \((W, \{ \prec_B \}_{B \in \text{MF}})\) is \( \text{Sub}(A) \)-transitive.

Proof. Let \( X,Y,Z \in W \) and \( \square \square B \in \text{Sub}(A) \) be such that \( X \prec_{\square B} Y \) and \( Y \prec_{\square B} Z \). If \( \square B \notin X \), then trivially \( X \prec_{\square B} Z \) by the definition of \( \prec_B \). If \( \square B \in X \), then \( \square \square B \in X \) because \( L \vdash \square B \rightarrow \square \square B \). Since \( X \prec_{\square B} Y \), we have \( \square B \in Y \). Also, since \( Y \prec_{\square B} Z \), we have \( B \in Z \). By the definition of \( \prec_B \), we obtain \( X \prec_B Z \). Therefore, \((W, \{ \prec_B \}_{B \in \text{MF}})\) is \( \text{Sub}(A) \)-transitive.

Our proof is finished.

Furthermore, from our proofs of Fact 3.2 and Theorems 3.12, 3.13, and 3.14, we obtain that the sets of all theorems of \( N \), \( \text{NR} \), \( N4 \), and \( \text{NR4} \) are primitive recursive. For example, to show that \( A \in \text{MF} \) is \( N4 \)-unprovable, it is sufficient to find a finite fragment \((W, \{ \prec_B \}_{B \in \text{Sub}(A)}, \models)\) of a \( \text{Sub}(A) \)-transitive \( N \)-model in which \( A \) is false such that the cardinality of \( W \) is smaller than \( 2^{2^n} \) where \( n \) is the number of subformulas of \( A \). Thus, a primitive recursive algorithm that searches for such finite structures determines whether each \( A \in \text{MF} \) is provable in \( N4 \) or not.

4 Arithmetical completeness of \( N \)

It is easy to see that for any provability predicate \( \text{Pr}_T(x) \) of \( T \), \( N \subseteq \text{PL}(\text{Pr}_T) \). Moreover, by our definition of provability predicates, we have the following theorem:

Theorem 4.1 (The arithmetical soundness of \( N \)). For any \( A \in \text{MF} \), any provability predicate \( \text{Pr}_T(x) \) of \( T \), and any arithmetical interpretation \( f \) based on \( \text{Pr}_T(x) \), if \( N \vdash A \), then \( \text{PA} \vdash f(A) \).

In this section, we prove that \( N \) is exactly the provability logic of all provability predicates. Moreover, we prove that \( N \) is one of the logics considered in Problem 2.2, namely, there exists a \( \Sigma_1 \) provability predicate \( \text{Pr}_T(x) \) of \( T \) such that \( N = \text{PL}(\text{Pr}_T) \).
**Theorem 4.2** (The uniform arithmetical completeness of \(N\)). There exist a \(\Sigma_1\) provability predicate \(Pr_T(x)\) of \(T\) and an arithmetical interpretation \(f\) based on \(Pr_T(x)\) such that for any \(A \in MF\), \(N \vdash A\) if and only if \(T \vdash f(A)\).

Before proving the theorem, we prepare a primitive recursive function \(h\) which plays an important role in our proofs of the theorems in this paper. The function \(h\) was originally introduced in [11] to prove the existence of a Rosser provability predicate whose provability logic is exactly the logic KD.

We say that an \(L_A\)-formula is *propositionally atomic* if it is not a Boolean combination of its proper subformulas. For each propositionally atomic formula \(\varphi\), we prepare a propositional variable \(p_\varphi\). We define the primitive recursive mapping \(I\) from \(L_A\)-formulas to propositional formulas as follows:

1. For each propositionally atomic formula \(\varphi\), \(I(\varphi) = p_\varphi\);
2. \(I(\neg \psi) = \neg I(\psi)\) for \(\circ \in \{\land, \lor, \rightarrow\}\);
3. \(I(\varphi \circ \psi) = I(\varphi) \circ I(\psi)\) for \(\circ \in \{\land, \lor, \rightarrow\}\).

It is clear that \(I\) is an injection. Let \(\varphi\) be an \(L_A\)-formula and \(X\) be a finite set of \(L_A\)-formulas. We say that \(\varphi\) is a *tautological consequence* (t.c.) of \(X\) if \(\bigwedge_{\psi \in X} I(\psi) \rightarrow I(\varphi)\) is a tautology. The method of constructing Rosser provability predicates satisfying D2 using truth assignments of classical propositional logic is due to Arai [1], and the idea of using t.c.’s is from [11].

For each natural number \(n\), let \(P_{T,n}\) be the set of all \(L_A\)-formulas having a \(T\)-proof with the Gödel number less than or equal to \(n\). It is proved that the set \(\{(n, \varphi) \mid \varphi\text{ is a t.c. of }P_{T,n}\}\) is primitive recursive. The above notions and sets are formalized in \(PA\). In particular, we suppose that \(P_{T,n}\) is formalized by using the proof predicate \(\text{Proof}_T(x, y)\).

The function \(h\) is defined as follows by using the formalized recursion theorem:

- \(h(0) = 0\).
- \(h(m + 1) = \begin{cases} i & \text{if } h(m) = 0 \\ i = \min\{j \in \omega \setminus \{0\} \mid \neg S(j)\text{ is a t.c. of }P_{T,m}\}, \\ h(m) & \text{otherwise.} \end{cases}\)

Here, \(S(x)\) is the \(\Sigma_1\) formula \(\exists y(h(y) = x)\). Unlike the Solovay function by the same name used in the proof of Solovay’s arithmetical completeness theorem, our function \(h\) does not track the structure of models, but is simply used to refer to the numbers \(m\) and \(i\) such that \(h(m) = 0\) and \(h(m + 1) = i \neq 0\). For such \(m\) and \(i\), it is shown that \(i \leq m\). It follows that \(h\) is a primitive recursive function (See [11] p. 603 for details). It is also shown that the following proposition holds.

**Proposition 4.3** (Cf. [11] Lemma 3.2.)

1. \(PA \vdash \forall x \forall y(0 < x < y \land S(x) \rightarrow \neg S(y))\).
2. \( \text{PA} \vdash \neg \text{Con}_T \leftrightarrow \exists x (S(x) \land x \neq 0) \), where \( \text{Con}_T \) is the \( \Pi_1 \) consistency statement \( \neg \text{Prov}_T(\langle 0 = 1 \rangle) \).

3. For each \( i \in \omega \setminus \{0\}, \ T \nvdash S(i) \).

4. For each \( n \in \omega \), \( \text{PA} \vdash \forall x \forall y (h(x) = 0 \land h(x + 1) = y \land y \neq 0 \rightarrow x > \pi) \).

We are ready to prove Theorem 4.2.

**Proof of Theorem 4.2** Let \( (A_n)_{n \in \omega} \) be a primitive recursive enumeration of all \( \text{N} \)-unprovable \( \mathcal{L}(\square) \)-formulas. For each \( n \in \omega \), let \( (W_n, \{ <_{n,B} \}_{B \in \text{MF}, \models n}) \) be a primitive recursively constructed finite \( \text{N} \)-model falsifying \( A_n \) (See Fact 3.3 and the comments in the last paragraph of Section 3). We may assume that \( \{W_n\}_{n \in \omega} \) is a pairwise disjoint family of subsets of \( \omega \) and \( \bigcup_{n \in \omega} W_n = \omega \setminus \{0\} \). We may also assume that for each \( i > 0 \), we can primitive recursively find the unique \( n \) such that \( i \in W_n \). Let \( \mathcal{M} = (W, \{ <_B \}_{B \in \text{MF}, \models} \) be an \( \text{N} \)-model defined as follows:

- \( W := \bigcup_{n \in \omega} W_n = \omega \setminus \{0\} \).
- \( x <_B y : \iff x, y \in W_n \) and \( x <_{n,B} y \) for some \( n \in \omega \).
- \( x \models p : \iff x \in W_n \) and \( x \models_n p \) for some \( n \in \omega \).

We may assume that \( \mathcal{M} \) is primitive recursively represented in \( \text{PA} \). Moreover, we assume that \( \text{PA} \) proves basic properties of \( \mathcal{M} \).

For each primitive recursive function \( g \) enumerating all theorems of \( T \), let \( \text{Pr}_g(x) \) be the \( \Sigma_1 \) formula \( \exists y (g(y) = x \land \text{Fml}_{\mathcal{L}_A}(x)) \). Then, \( \text{Pr}_g(x) \) is a provability predicate of \( T \). We define the arithmetical interpretation \( f_g \) based on \( \text{Pr}_g(x) \) by \( f_g(p) := \exists x (S(x) \land x \neq 0 \land x \models p) \). From an index of such a function \( g \) and \( A \in \text{MF} \), the \( \mathcal{L}_A \)-sentence \( f_g(A) \) is primitive recursively computed. Furthermore, it is shown that each \( f_g \) is an injective mapping, and so from an index of \( g \) and \( f_g(A) \), the \( \mathcal{L}(\square) \)-formula \( A \) is recovered primitive recursively.

Next, we define the primitive recursive function \( g_0 \) enumerating all theorems of \( T \). The definition of \( g_0 \) consists of two procedures. The definition starts with Procedure 1. The values of \( g_0 \) are defined step by step in the procedure by referring to \( T \)-proofs according to the proof predicate \( \text{Proof}_T(x, y) \). At the first time the value of the function \( h \) is non-zero, the definition of \( g_0 \) switches to Procedure 2. By using the formalized recursion theorem, the arithmetical interpretation \( f_{g_0} \) based on the provability predicate \( \text{Pr}_{g_0}(x) \) is used in the definition of \( g_0 \). In the construction, we identify each \( \mathcal{L}_A \)-formula with its Gödel number.

**Procedure 1**

**Stage \( m \).**

- If \( h(m + 1) = 0 \), then
  
  \[
  g_0(m) = \begin{cases} 
  \varphi & \text{if } m \text{ is a } T \text{-proof of } \varphi, \\
  0 & \text{otherwise}.
  \end{cases}
  \]
Go to Stage \( m + 1 \).

- If \( h(m + 1) \neq 0 \), then go to Procedure 2.

**Procedure 2**

Let \( m, i \neq 0 \) and \( n \) be such that \( h(m) = 0 \), \( h(m + 1) = i \), and \( i \in W_n \).

Recall from Section 2 that \( \{ \xi_t \}_{t \in \omega} \) is the primitive recursive enumeration of all \( \mathcal{L}_A \)-formulas arranged in ascending order of Gödel numbers. Define

\[
g_0(m + t) = \begin{cases} 
\xi_t & \text{if } \xi_t \equiv f_{g_0}(B) & \& i \models \Box B \text{ for some } \Box B \in \text{Sub}(A_n), \\
0 & \text{otherwise.}
\end{cases}
\]

The definition of \( g_0 \) is finished.

**Claim 4.4.** \( \text{PA} + \text{Con}_T \vdash \forall x \forall y \bigl( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Proof}_T(x, y) \iff x = g_0(y)) \bigr) \).

**Proof.** We argue in \( \text{PA} + \text{Con}_T \): By Proposition 4.3.2, \( h(x) = 0 \) for all \( x \). Thus, the construction of \( g_0 \) never switches to Procedure 2. Then, for any \( \mathcal{L}_A \)-formula \( \varphi \) and number \( a \), we have that \( a \) is a \( T \)-proof of \( \varphi \) if and only if \( \varphi = g_0(a) \). \( \Box \)

Then, it is shown that for any \( \mathcal{L}_A \)-formula \( \varphi \) and \( n \in \omega \), \( \text{PA} \vdash \text{Proof}_T(\varphi, n) \) if and only if \( \text{PA} \vdash \forall \varphi \exists n, \text{Sub}(A_n) \). It follows that \( \text{Pr}_{g_0}(x) \) is a \( \Sigma_1 \) provability predicate of \( T \).

**Claim 4.5.** Let \( i \in W_n \) and \( B \in \text{Sub}(A_n) \).

1. If \( i \models B \), then \( \text{PA} \vdash S(\overline{i}) \rightarrow f_{g_0}(B) \).
2. If \( i \not\models B \), then \( \text{PA} \vdash S(\overline{i}) \rightarrow \neg f_{g_0}(B) \).

**Proof.** Clauses 1 and 2 are proved simultaneously by induction on the construction of \( B \in \text{Sub}(A_n) \). Firstly, we prove the base step of the induction. The case that \( B \) is \( \bot \) is trivial. We prove the case that \( B \) is a propositional variable \( p \).

1. Suppose \( i \models p \). We have \( \text{PA} \vdash S(\overline{i}) \rightarrow \exists x (S(x) \land x \neq 0 \land x \models p) \), and hence \( \text{PA} \vdash S(\overline{i}) \rightarrow f_{g_0}(p) \).
2. Suppose \( i \not\models p \). Since \( \text{PA} \vdash S(\overline{i}) \rightarrow \forall x (S(x) \land x \neq 0 \rightarrow x = \overline{i}) \) by Proposition 4.3.1, we have that \( \text{PA} \vdash S(\overline{i}) \rightarrow \forall x (S(x) \land x \neq 0 \rightarrow x \not\models p) \).

Equivalently, \( \text{PA} \vdash S(\overline{i}) \rightarrow \neg f_{g_0}(p) \).

Secondly, we prove the induction step. The cases of \( \neg, \lor, \land, \) and \( \rightarrow \) are easy. So, we give only a proof of the case that \( B \) is of the form \( \square C \), where the claim holds for \( C \).

1. Suppose \( i \models \square C \). We reason in \( \text{PA} + S(\overline{i}) \): Let \( m \) be such that \( h(m) = 0 \) and \( h(m + 1) = i \). Let \( t \) be the number such that \( \xi_t \equiv f_{g_0}(C) \). Since \( i \models \square C \) and \( \square C \in \text{Sub}(A_n) \), we have \( g_0(m + t) = f_{g_0}(C) \). Thus, \( \text{Pr}_{g_0}(\forall f_{g_0}(C)) \) holds. This means that \( f_{g_0}(\square C) \) holds.
2. Suppose \( i \not\models \square C \). Then, there exists a \( j \in W_n \) such that \( i \not\prec n, C \) and \( j \not\prec n, C \). By the induction hypothesis, \( \text{PA} \vdash S(\overline{j}) \rightarrow \neg f_{g_0}(C) \). Let \( p \) be a \( T \)-proof of \( S(\overline{j}) \) \( \rightarrow \neg f_{g_0}(C) \).

We argue in \( \text{PA} + S(\overline{i}) \): Let \( m \) be such that \( h(m) = 0 \) and \( h(m + 1) = i \).
Corollary 4.6.

\[ N = \bigcap \{ \text{PL}(\text{Pr}_T) \mid \text{Pr}_T(x) \text{ is a provability predicate of } T \}, \]
\[ = \bigcap \{ \text{PL}(\text{Pr}_T) \mid \text{Pr}_T(x) \text{ is a } \Sigma_1 \text{ provability predicate of } T \}. \]

Moreover, there exists a \( \Sigma_1 \) provability predicate \( \text{Pr}_T(x) \) of \( T \) such that \( N = \text{PL}(\text{Pr}_T) \).

5 Arithmetical completeness of N4

In this section, we investigate provability predicates satisfying the condition \( D_3 \). It is easy to show that for any provability predicate \( \text{Pr}_T(x) \) satisfying \( D_3, N_4 \subseteq \text{PL}(\text{Pr}_T) \). We prove that \( N_4 \) is exactly the provability logic of all provability predicates satisfying \( D_3 \). Moreover, we prove the following uniform version of arithmetical completeness.

Theorem 5.1 (The uniform arithmetical completeness of N4). There exists a \( \Sigma_1 \) provability predicate \( \text{Pr}_T(x) \) of \( T \) such that

1. for any \( A \in \text{MF} \) and any arithmetical interpretation \( f \) based on \( \text{Pr}_T(x) \), if \( N_4 \vdash A \), then \( \text{PA} \vdash f(A) \); and

2. there exists an arithmetical interpretation \( f \) based on \( \text{Pr}_T(x) \) such that for any \( A \in \text{MF}, N_4 \vdash A \) if and only if \( T \vdash f(A) \).

Proof. Let \( (A_n)_{n \in \omega} \) be a primitive recursive enumeration of all \( N_4 \)-unprovable \( \mathcal{L}(\Box) \)-formulas. For each \( n \in \omega \), let \( (W_n, \{ \langle n, B \rangle \}_{B \in \text{MF}, n}, \models_n) \) be a primitive recursively constructed finite \( \text{Sub}(A_n) \)-transitive \( N \)-model falsifying \( A_n \). Let \( \mathcal{M} \) be the primitive recursively representable \( N \)-model defined as the disjoint union of these finite \( N \)-models as in the proof of Theorem 4.2.

We define the primitive recursive function \( g_1 \) corresponding to this theorem. By the formalized recursion theorem, we use \( \text{Pr}_{g_1} \) and \( f_{g_1} \) in the definition
of $g_1$ where $Pr_{g_1}(x)$ is the formula $\exists y (g_1(y) = x \land \text{Fml}_A(x))$ and $f_{g_1}$ is the
arithmetical interpretation based on $Pr_{g_1}(x)$ defined by $f_{g_1}(p) \equiv \exists x (S(x) \land x \neq
0 \land x \vdash p)$. As in the definition of the function $g_0$, the definition of $g_1$ consists of
Procedures 1 and 2. Moreover, the definition of Procedure 1 is completely same as that of $g_0$, so here we only give the definition of Procedure 2. Unlike the function $g_0$, to ensure that $Pr_{g_1}(x)$ satisfies $\textbf{D3}$, in Procedure 2, the function $g_1$
outputs the sentences of the form $Pr_{g_1}(\lnot \phi)$ for already output formulas $\phi$.

**Procedure 2**
Let $m, i \neq 0$, and $n$ be such that $h(m) = 0$, $h(m + 1) = i$, and $i \in W_n$. Define

$$g_1(m+1) = \begin{cases} 
\xi_t & \text{if } \xi_t \equiv f_{g_1}(B) \& i \vdash _n \Box B \text{ for some } \Box B \in \text{Sub}(A_n) \\
n & \text{otherwise.}
\end{cases}$$

Since Procedure 1 in the definition of $g_1$ is same as that of $g_0$, the following claim is proved as in the proof of Theorem 4.2.

**Claim 5.2.** $PA + Con_T \vdash \forall x \forall y \left( \text{Fml}_A(x) \rightarrow (\text{Proof}_T(x, y) \leftrightarrow x = g_1(y)) \right)$.

Hence, $Pr_{g_1}(x)$ is a $\Sigma_1$ provability predicate of $T$. We prove that $Pr_{g_1}(x)$
satisfies the condition $\textbf{D3}$.

**Claim 5.3.** For any $L_A$-formula $\phi$, $PA \vdash Pr_{g_1}(\lnot \phi) \rightarrow Pr_{g_1}(Pr_{g_1}(\lnot \phi))$.

**Proof.** Since $Pr_{g_1}(\lnot \phi)$ is a $\Sigma_1$ sentence, $PA \vdash Pr_{g_1}(\lnot \phi) \rightarrow \text{Prov}_T(Pr_{g_1}(\lnot \phi))$.

By Claim 5.2, $PA + Con_T \vdash \forall x \left( \text{Fml}_A(x) \rightarrow (\text{Proof}_T(x) \leftrightarrow Pr_{g_1}(x)) \right)$. Thus, we have $PA + Con_T \vdash Pr_{g_1}(\lnot \phi) \rightarrow Pr_{g_1}(Pr_{g_1}(\lnot \phi))$.

We reason in $PA + \neg Con_T + Pr_{g_1}(\lnot \phi)$: By Proposition 4.3,2, there exists an
$i \neq 0$ such that $S(i)$ holds. Let $m$ and $n$ be such that $h(m) = 0$, $h(m + 1) = i$, and $i \in W_n$. Since $Pr_{g_1}(\lnot \phi)$ holds, $\phi$ is output by $g_1$. Let $s$ be such that
$\xi_s \equiv \phi$.

If $\phi$ is output in Procedure 1, then $\phi = g_1(k)$ for some $k < m$. If $\phi$ is
output in Procedure 2, then $\phi = g_1(m + s)$. In either case, we have that
$\phi \in \{ g_1(0), \ldots, g_1(m + s) \}$. Let $u$ be such that $\xi_u \equiv Pr_{g_1}(\lnot \phi)$. Since the Gödel
number of $Pr_{g_1}(\lnot \phi)$ is larger than that of $\phi$, we have $s < u$ by the choice of
the enumeration $\{ \xi_i \}_{i \in \omega}$. Since there is an $l < m + u$ such that $g_1(l) = \phi$, we have that
$g_1(m + u) = Pr_{g_1}(\lnot \phi)$. Thus, $Pr_{g_1}(\lnot Pr_{g_1}(\lnot \phi))$ holds.

We have proved $PA + \neg Con_T \vdash Pr_{g_1}(\lnot \phi) \rightarrow Pr_{g_1}(\lnot Pr_{g_1}(\lnot \phi))$. By the law
of excluded middle, we conclude $PA \vdash Pr_{g_1}(\lnot \phi) \rightarrow Pr_{g_1}(\lnot Pr_{g_1}(\lnot \phi))$.

**Claim 5.4.** Let $i \in W_n$ and $B \in \text{Sub}(A_n)$.

1. If $i \vdash _n B$, then $PA \vdash S(\bar{i}) \rightarrow f_{g_1}(B)$.
2. If $i \not\vdash _n B$, then $PA \vdash S(\bar{i}) \rightarrow \neg f_{g_1}(B)$.
Corollary 5.5. This is proved by induction on the construction of \( B \in \text{Sub}(A_n) \). We only prove the case that \( B \) is of the form \( \Box C \). Clause 1 is proved in the similar way as in the proof of Claim 4.3.

2. Suppose \( i \nmid_n \Box C \). We prove in \( \text{PA} + S(\overline{t}) \) that \( f_{g_1}(C) \) is not output by \( g_1 \). We distinguish the following two cases:

- **Case 1:** \( C \) is not of the form \( \Box D \).
  There exists a \( j \in W_n \) such that \( i \prec_n C j \) and \( j \nmid_n C \). By the induction hypothesis, \( \text{PA} \vdash S(j) \rightarrow \neg f_{g_1}(C) \). Let \( p \) be a \( T \)-proof of \( S(j) \rightarrow \neg f_{g_1}(C) \).
  We proceed in \( \text{PA} + S(\overline{t}) \): Let \( m \) be such that \( h(m) = 0 \) and \( h(m + 1) = i \).
  By Proposition 4.3.4, we have \( m > p \), and hence \( S(j) \rightarrow \neg f_{g_1}(C) \) is in \( \text{Pr}_{T,m-1} \).
  If \( f_{g_1}(C) \) is output in Procedure 1, then \( f_{g_1}(C) \in \text{Pr}_{T,m-1} \), and hence \( \neg S(j) \) is a t.c. of \( \text{Pr}_{T,m-1} \). This contradicts \( h(m) = 0 \).
  If \( f_{g_1}(C) \) is output in Procedure 2, then \( \xi_t \equiv f_{g_1}(C) \) and \( g_1(m + t) = f_{g_1}(C) \) for some \( t \). Since \( C \) is not of the form \( \Box D \), there is no \( \varphi \) such that \( f_{g_1}(C) \equiv \text{Pr}_{g_1}(\Box \varphi) \). By the definition of \( g_1 \), \( f_{g_1}(C) \equiv f_{g_1}(D) \) and \( i \nmid_n \Box D \) for some \( \Box D \in \text{Sub}(A_n) \). It follows that \( C \equiv D \) and this contradicts \( i \nmid_n \Box C \).

- **Case 2:** \( C \) is of the form \( \Box D \).
  Then, \( \Box \Box D \in \text{Sub}(A_n) \). Since \( (W_n, \{ \prec_n, B \}_{B \in \text{MF}}, \models_n) \) is \( \text{Sub}(A_n) \)-transitive, \( \Box D \rightarrow \Box \Box D \) is valid in the model. Since \( i \nmid_n \Box D \), we have \( i \nmid_n \Box D \).
  By the induction hypothesis,
  \[
  \text{PA} \vdash S(\overline{t}) \rightarrow \neg f_{g_1}(\Box D) \tag{1}
  \]
  We reason in \( \text{PA} + S(\overline{t}) \): If \( f_{g_1}(\Box D) \) is output in Procedure 1, then \( f_{g_1}(\Box D) \in \text{Pr}_{T,m-1} \). By [1] and Proposition 4.3.4, \( S(\overline{t}) \rightarrow \neg f_{g_1}(\Box D) \) is also in \( \text{Pr}_{T,m-1} \). Hence, \( \neg S(\overline{t}) \) is a t.c. of \( \text{Pr}_{T,m-1} \), a contradiction.
  If \( f_{g_1}(\Box D) \) is output in Procedure 2, then \( \xi_t \equiv f_{g_1}(\Box D) \) and \( g_1(m + t) = f_{g_1}(\Box D) \) for some \( t \). If \( f_{g_1}(\Box D) \equiv f_{g_1}(E) \) and \( i \nmid_n \Box E \) for some \( \Box E \in \text{Sub}(A_n) \), then \( \Box D \equiv E \) and \( i \nmid_n \Box \Box D \), a contradiction. Thus, we have that \( f_{g_1}(\Box D) \equiv \text{Pr}_{g_1}(\Box \varphi) \) and \( g_1(l) = \varphi \) for some \( \varphi \) and \( l < m + t \). Since \( g_1(l) = \varphi \), we have that \( \text{Pr}_{g_1}(\Box \varphi) \) holds, and hence \( f_{g_1}(\Box D) \) holds. This contradicts [1].

In either case, we have shown in \( \text{PA} + S(\overline{t}) \) that \( f_{g_1}(C) \) is not output by \( g_1 \). Therefore, \( \neg f_{g_1}(\Box C) \) holds in \( \text{PA} + S(\overline{t}) \). \( \square \)

The first clause of the theorem follows from Claims 5.2 and 5.3. The second clause follows from Proposition 4.3.3 and Claim 5.4 \( \square \)

**Corollary 5.5.**

\[
N_4 = \bigcap \{ \text{PL}(\text{Pr}_T) \mid \text{Pr}_T(x) \text{ is a provability predicate of } T \text{ satisfying D3} \},
\]

\[
= \bigcap \{ \text{PL}(\text{Pr}_T) \mid \text{Pr}_T(x) \text{ is a } \Sigma_1 \text{ provability predicate of } T \text{ satisfying D3} \}.
\]
Moreover, there exists a $\Sigma_1$ provability predicate $\Pr_T(x)$ of $T$ such that $N4 = PL(\Pr_T)$.

## 6 Arithmetical completeness of NR

It is known that for any Rosser provability predicate $\Pr^R_T(x)$ of $T$ and any $L_A$-formula $\varphi$, if $T \vdash \neg \varphi$, then $\text{PA} \vdash \neg \Pr^R_T(\ulcorner \varphi \urcorner)$. This fact corresponds to the closure under the rule $\text{Ros} \frac{}{\neg A \neg \Box A}$, and hence it is shown that $NR \subseteq PL(\Pr^R_T)$.

Moreover, we obtain the following theorem:

**Theorem 6.1** (The arithmetical soundness of NR). For any $A \in MF$, any Rosser provability predicate $\Pr^R_T(x)$ of $T$, and any arithmetical interpretation $f$ based on $\Pr^R_T(x)$, if $NR \vdash A$, then $\text{PA} \vdash f(A)$.

Our logic NR is a candidate for the axiomatization of the logic $L^R$ introduced in Section 2. In this section, we prove that this is the case. Namely, we prove that NR is exactly the provability logic of all Rosser provability predicates.

Firstly, we prove the coincidence of NR and $L^R$ without going through arithmetic. For each $L(\Box)$-formula $A$, let $A^{\mathbb{B}}$ be the $L(\mathbb{B})$-formula obtained from $A$ by replacing every $\Box$ in $A$ with $\mathbb{B}$.

**Theorem 6.2.** For any $L(\Box)$-formula $A$, the following are equivalent:

1. $NR \vdash A$.
2. $GR \vdash A^{\mathbb{B}}$.

**Proof.** Since the rules $\mathbb{B}A$ and $\frac{}{\neg A \neg \Box A}$ are admissible in GR, the implication $(1 \Rightarrow 2)$ is straightforward.

$(2 \Rightarrow 1)$: We prove the contrapositive. Suppose $NR \not\vdash A$. By Theorem 3.12 there exists a serial $N$-model $(W, \{\prec B\}_{B \in MF}, \models)$ and an element $w \in W$ such that $w \not\models A$. Let $r$ be any object not in $W$ and define $W^* := W \cup \{r\}$. We define binary relations $\prec^*_B$ on $W^*$ for every $L(\Box)$-formula $B$ as follows:

$$\prec^*_B := \begin{cases} \prec_C & B \text{ is of the form } C^{\mathbb{B}} \text{ for some } L(\Box)\text{-formula } C, \\ W^2 & \text{otherwise.} \end{cases}$$

We define the satisfaction relation $\models^*$ between the elements of $W^*$ and $L(\Box, \mathbb{B})$-formulas as follows: Let $x \in W$, $p$ be any propositional variable, and $B$ be any $L(\Box, \mathbb{B})$-formula,

- $x \models^* p \iff x \models p$
- $r \models^* p$
- $x \models^* \Box B$
- $r \models^* \Box B \iff y \models^* B$ for all $y \in W$.
• \( x \vdash^* \Box B \iff y \vdash^* B \) for all \( y \in W \) such that \( x \prec^*_B y \);

• \( r \vdash^* \Box B \iff y \vdash^* B \) for all \( y \in W \);

• \( \vdash^* \) fulfills the usual conditions for \( \bot, \neg, \land, \lor \).

By the definition of \( \vdash^* \), it is easy to see that all axioms of \( \text{GR}^- \) are true in all \( x \in W \). Also, it can be shown that all axioms of \( \text{GR}^- \) are true in \( r \). We give only a proof of the fact that \( \Box \neg B \rightarrow \Box \neg \Box B \) is true in \( r \).

Suppose \( r \vdash^* \Box \neg B \). Let \( x \) be any element of \( W \). If \( B \) is of the form \( C\Box \) for some \( C \in \text{MF} \), then \( \prec^*_B = \prec_C \). Since \( \prec_C \) is serial, we find a \( y \in W \) such that \( x \prec_C y \). Thus, \( x \prec^*_B y \). Otherwise, we have \( \prec^*_B = W^2 \), and hence \( x \prec^*_B x \). In either case, we obtain a \( y \in W \) such that \( x \prec^*_B y \). By the supposition, we have \( y \vdash^* \neg B \), and hence \( x \vdash^* \neg \Box B \). We conclude \( r \vdash^* \Box \neg \Box B \).

It is easy to show that the rules MP and \( \text{NeC} \) for \( \Box \) preserve validity in the model \( (W^*, \{ \prec^*_B \}, \vdash^*) \). So, we obtain that all theorems of \( \text{GR}^- \) are valid in the model.

By induction on the construction of \( \mathcal{L}(\Box) \)-formula \( B \), we can prove that for any \( x \in W \), \( x \vdash B \) if and only if \( x \vdash^* B \). Since \( w \not\vdash A \), we get \( w \not\vdash^* A \). Thus, \( r \not\vdash^* \Box (A) \). Since every theorem of \( \text{GR}^- \) is true in all elements of \( W^* \), we obtain \( \text{GR}^- \not\vdash \Box A \). By Theorem 2.3, we conclude that \( \text{GR}^- \not\vdash A \). □

Therefore, \( \text{NR} \) is exactly the \( \Box \)-free fragment \( L^R \) of \( \text{GR} \). By Corollary 2.6 and Theorem 6.2, we obtain that the provability logic of all Rosser provability predicates of \( T \) coincides with \( \text{NR} \).

**Corollary 6.3.** If \( T \) is \( \Sigma_1 \)-sound, then

\[
\text{NR} = \bigcap \{ \text{PL}(\text{Pr}^R_T) \mid \text{Pr}^R_T(x) \text{ is a Rosser provability predicate of } T \}.
\]

Moreover, there exists a Rosser provability predicate \( \text{Pr}^R_T(x) \) of \( T \) such that \( \text{NR} = \text{PL}(\text{Pr}^R_T) \).

Secondly, we directly prove the arithmetical completeness theorem for \( \text{NR} \) without using the arithmetical completeness theorem for \( \text{GR} \), to show that Corollary 6.3 holds without assuming the \( \Sigma_1 \)-soundness of \( T \).

**Theorem 6.4.** (The uniform arithmetical completeness of \( \text{NR} \)). There exists a Rosser provability predicate \( \text{Pr}^R_T(x) \) of \( T \) and an arithmetical interpretation \( f \) based on \( \text{Pr}^R_T(x) \) such that for any \( A \in \text{MF} \), \( \text{NR} \vdash A \) if and only if \( T \vdash f(A) \).

**Proof.** Let \( (A_n)_{n \in \omega} \) be a primitive recursive enumeration of all \( \text{NR} \)-unprovable \( \mathcal{L}(\Box) \)-formulas. For each \( n \in \omega \), let \( (W_n, \{ \prec^*_B \}_{B \in \text{MF}, \vdash^*}) \) be a primitive recursively constructed finite Sub\( (A) \)-serial \( N \)-model in which \( A_n \) is not valid. Let \( \mathcal{M} = (W, \{ \prec_B \}_{B \in \text{MF}, \vdash^*}) \) be the \( N \)-model defined as in the previous sections. We define the corresponding primitive recursive function \( g_2 \) enumerating all theorems of \( T \). Let \( \text{Pr}^R_{g_2}(x) \) be the formula

\[
\exists y(\text{Fml}_{\mathcal{L}_A}(x) \land x = g_2(y) \land \forall z < y \neg \dot{(x)}(z)) = g_2(z).
\]
In the definition of \(g_2\), we use the arithmetical interpretation \(f_{g_2}\) based on \(\Pr_{g_2}(x)\) defined as \(f_{g_2}(p) \equiv \exists x(S(x) \land x \neq 0 \land x \models p)\). Procedure 1 in the construction of \(g_2\) is same as that of \(g_0\), and so we only give the definition of Procedure 2. Roughly speaking, \(g_2\) is defined so that if \(S(\vec{t})\) holds for \(i \in W_n\), then in Procedure 2, for \(\square B \in \text{Sub}(A_n)\) which is false in \(i\), \(g_2\) outputs \(\neg f_{g_2}(B)\) before any output of \(f_{g_2}(B)\).

**Procedure 2**

Let \(m, i \neq 0,\) and \(n\) be such that \(h(m) = 0, h(m + 1) = i,\) and \(i \in W_n\). We define the finite set \(X\) of \(\mathcal{L}_A\)-sentences as follows:

\[
X := \{ \neg f_{g_2}(B) \mid i \not\equiv_n \square B \& \square B \in \text{Sub}(A_n) \}.
\]

Let \(\chi_0, \ldots, \chi_{k - 1}\) be the listing of all elements of \(X\) arranged in descending order of Gödel numbers. For \(l < k\), define

\[
g_2(m + l) = \chi_l.
\]

And define

\[
g_2(m + k + t) = \xi_t.
\]

The definition of \(g_2\) is finished.

**Claim 6.5.**

1. \(\text{PA} + \text{Con}_T \vdash \forall x \forall y \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Proof}_T(x, y) \leftrightarrow x = g_2(y)) \right)\).

2. \(\text{PA} \vdash \forall x \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Prov}_T(x) \leftrightarrow \Pr_{g_2}(x)) \right)\).

**Proof.** Clause 1 is proved similarly as in the proof of Theorem 4.2.

2. By Clause 1, \(\text{PA} + \text{Con}_T \vdash \forall x \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Prov}_T(x) \leftrightarrow \Pr_{g_2}(x)) \right)\). Also, \(\text{PA} + \neg \text{Con}_T \vdash \forall x \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow \text{Prov}_T(x) \right)\). Proposition 4.3.2 says that \(\text{PA}\) verifies that if \(T\) is inconsistent, then the construction of \(g_2\) eventually switches to Procedure 2. Since \(g_2\) outputs all \(\mathcal{L}_A\)-formulas in Procedure 2, we have \(\text{PA} + \neg \text{Con}_T \vdash \forall x \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow \Pr_{g_2}(x) \right)\). Hence, \(\text{PA} + \neg \text{Con}_T \vdash \forall x \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Prov}_T(x) \leftrightarrow \Pr_{g_2}(x)) \right)\). By the law of excluded middle, we conclude \(\text{PA} \vdash \forall x \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Prov}_T(x) \leftrightarrow \Pr_{g_2}(x)) \right)\). \(\Box\)

It follows from this claim, \(\Pr_{g_2}(x)\) is a Rosser provability predicate of \(T\).

**Claim 6.6.** Let \(i \in W_n\) and \(B \in \text{Sub}(A_n)\).

1. If \(i \not\equiv_n B\), then \(\text{PA} \vdash S(\vec{t}) \rightarrow f_{g_2}(B)\).

2. If \(i \not\equiv_n B\), then \(\text{PA} \vdash S(\vec{t}) \rightarrow \neg f_{g_2}(B)\).
Proof. This claim is proved by induction on the construction of \( B \in \text{Sub}(A_n) \). We only give a proof of the case \( B \equiv \Box C \).

1. Suppose that \( i \not| C \). Since \( \Box C \in \text{Sub}(A_n) \) and \( \{ \prec_n, B \}_{B \in \text{MF}, \not| C} \) is \( \text{Sub}(A_n) \)-serial, there is a \( j \in W_n \) such that \( i \not| j \). Then, \( j \not| C \). By the induction hypothesis, \( \mathcal{P} \vdash S(j) \rightarrow f_{g_2}(C) \). Let \( p \) be a \( T \)-proof of \( S(j) \rightarrow f_{g_2}(C) \).

We argue in \( \mathcal{P} + S(j) \): Let \( m \) be such that \( h(m) = 0 \) and \( h(m + 1) = i \). Also, let \( X \) be the finite set of \( L_{\text{MF}} \)-formulas as in Procedure 2 and let \( k \) be the cardinality of \( X \). By Proposition 4.3.4, \( m > p \), and hence \( S(j) \rightarrow f_{g_2}(C) \) is in \( P_{T,m-1} \).

If \( \neg f_{g_2}(C) \in P_{T,m-1} \), then \( \neg S(j) \) is a t.c. of \( P_{T,m-1} \), a contradiction. Hence, \( \neg f_{g_2}(C) \notin P_{T,m-1} \), and so \( \neg f_{g_2}(C) \notin \{ g_2(0), \ldots, g_2(m - 1) \} \). If \( \neg f_{g_2}(C) \in X \), then there exists a \( \Box D \in \text{Sub}(A_n) \) such that \( \neg f_{g_2}(C) \equiv \neg f_{g_2}(D) \) and \( i \not| \Box D \). Then, we have \( C \equiv D \), and this contradicts \( i \not| C \). Thus, we have \( \neg f_{g_2}(C) \notin X \), that is, \( \neg f_{g_2}(C) \notin \{ g_2(m), \ldots, g_2(m + k - 1) \} \). Therefore, we obtain \( \neg f_{g_2}(C) \notin \{ g_2(0), \ldots, g_2(m + k - 1) \} \).

Let \( s \) and \( u \) be such that \( \xi_s \equiv f_{g_2}(C) \) and \( \xi_u \equiv \neg f_{g_2}(C) \). Then, \( s < u \), \( g_2(m + k + s) = f_{g_2}(C) \), and \( g_2(m + k + u) = \neg f_{g_2}(C) \). In particular, \( g_2(m + k + u) \) is the first output of \( \neg f_{g_2}(C) \) by \( g_2 \). Therefore, \( Pr_{g_2}^R(\neg f_{g_2}(C) \uparrow) \) holds. That is, \( f_{g_2}(\Box C) \) holds.

2. Suppose \( i \not| C \). Then, there exists a \( j \in W_n \) such that \( i \not| j \) and \( j \not| C \). By the induction hypothesis, \( \mathcal{P} + S(j) \vdash \neg f_{g_2}(C) \).

We reason in \( \mathcal{P} + S(j) \): Let \( m \) be such that \( h(m) = 0 \) and \( h(m + 1) = i \). Also, let \( X \) and \( k \) be as in the definition of \( g_2 \). As above, \( S(j) \rightarrow \neg f_{g_2}(C) \) is in \( P_{T,m-1} \). If \( f_{g_2}(C) \in P_{T,m-1} \), then \( \neg S(j) \) is a t.c. of \( P_{T,m-1} \), and this is a contradiction.

Thus, \( f_{g_2}(C) \notin P_{T,m-1} \), and hence \( f_{g_2}(C) \notin \{ g_2(0), \ldots, g_2(m - 1) \} \).

On the other hand, since \( \Box C \in \text{Sub}(A_n) \) and \( i \not| C \), we obtain \( \neg f_{g_2}(C) \in X \). That is, \( \neg f_{g_2}(C) \in \{ g_2(m), \ldots, g_2(m + k - 1) \} \). Since the Gödel number of \( \neg f_{g_2}(C) \) is larger than that of \( f_{g_2}(C) \), even if \( f_{g_2}(C) \in X \), \( \neg f_{g_2}(C) \) is listed earlier than \( f_{g_2}(C) \) in the listing \( \chi_0, \ldots, \chi_{k-1} \) of \( X \). Thus, \( \neg f_{g_2}(C) \) is output by \( g_2 \) earlier than any output of \( f_{g_2}(C) \). Therefore, \( Pr_{g_2}^R(\neg f_{g_2}(C) \uparrow) \) holds. That is, \( f_{g_2}(\Box C) \) holds.

The theorem follows from Proposition 4.3.3 and Claims 6.5 and 6.6.

Finally, we obtain that Corollary 6.3 holds regardless of whether \( T \) is \( \Sigma_1 \)-sound or not.

**Corollary 6.7.**

\[
\text{NR} = \bigcap \{ \text{PL}(Pr_T^R) \mid Pr_T^R(x) \text{ is a Rosser provability predicate of } T \}.
\]

Moreover, there exists a Rosser provability predicate \( Pr_T^R(x) \) of \( T \) such that \( \text{NR} = \text{PL}(Pr_T^R) \).
7 Arithmetical completeness of NR4

Arai \cite{1} proved the existence of Rosser provability predicates satisfying the condition D3. For such Rosser provability predicates \( \Pr_4^R(x) \), one has NR4 \( \subseteq \) PL(\( \Pr_4^R \)). In this section, we investigate the provability logic of Arai’s predicates, and prove that NR4 is exactly the provability logic of all Rosser provability predicates satisfying D3.

**Theorem 7.1** (The uniform arithmetical completeness of NR4). There exists a Rosser provability predicate \( \Pr_4^R(x) \) of \( T \) such that

1. for any \( A \in MF \) and any arithmetical interpretation \( f \) based on \( \Pr_4^R(x) \), if NR4 \( \vdash A \), then PA \( \vdash f(A) \); and

2. there exists an arithmetical interpretation \( f \) based on \( \Pr_4^R(x) \) such that for any \( A \in MF \), NR4 \( \vdash A \) if and only if T \( \vdash f(A) \).

**Proof.** Let \( (A_n)_{n \in \omega} \) be a primitive recursive enumeration of all NR4-unprovable \( L(\Box) \)-formulas. For each \( n \in \omega \), let \((W_n, \{\prec_{n,B}\}_{B \in MF, \models n})\) be a primitive recursively constructed finite \( \text{Sub}(A_n) \)-transitive and \( \text{Sub}(A_n) \)-serial \( \mathbf{N} \)-model falsifying \( A_n \). Let \( M = (W, \{\prec_B\}_{B \in MF, \models}) \) be the primitive recursively representable infinite model constructed as the disjoint union of \((W_n, \{\prec_{n,B}\}_{B \in MF, \models n})_{n \in \omega}\) as in the proof of Theorem 4.2. In particular, \( W = \omega \setminus \{0\} \).

Unlike the proofs in the previous sections, our proof of this theorem uses a different function \( h' \) instead of the function \( h \). By using the double recursion theorem, we simultaneously define the primitive recursive functions \( h' \) and \( g_3 \).

Firstly, we define the function \( h' \).

- \( h'(0) = 0 \).
- \( h'(m + 1) = \begin{cases} i & \text{if } h'(m) = 0 \\
& & \text{& } i = \min\{j \in \omega \setminus \{0\} \mid \neg S'(j) \text{ is a t.c. of } P_{T,m} \}
& \text{or } \exists \varphi < m \left[ \neg \varphi \notin P_{T,m} \cup X_{j,m} \right.
& \text{& } S'(j) \rightarrow \neg \Pr_1^R(\Box \varphi) \text{ is a t.c. of } P_{T,m} \left. \right] \} \\
h'(m) & \text{otherwise.} \end{cases} \)

Here, \( S'(x) \) is the \( \Sigma_1 \) formula \( \exists y(h'(y) = x) \). Also, \( \varphi < m \) means that the Gödel number of \( \varphi \) is smaller than \( m \). Also, for each \( j \in W_n \) and number \( m, X_{j,m} \) is the finite set

\[
\left\{ \neg f_{g_3}(D) \mid \Box D \in \text{Sub}(A_n) \quad \& \quad \exists l \in W_n \ [j \prec_{n,D} l \quad \& \quad S'(l) \rightarrow \neg f_{g_3}(D) \text{ is a t.c. of } P_{T,m}] \right\},
\]

where \( f_{g_3} \) is the arithmetical interpretation based on \( \Pr_1^R(x) \) defined as \( f_{g_3}(x) := \exists x (S'(x) \land x \neq 0 \land x \models p) \).

We find some \( r \in \omega \) such that \( A_r \equiv \bot \) since NR4 \( \not\models \bot \), and we fix any \( j_0 \in W_r \).

Here, we prove that if \( h'(m) = 0 \) and \( h'(m + 1) = i \neq 0 \), then \( i \leq \max\{j_0, m\} \).

It follows that \( h' \) is actually a primitive recursive function. Suppose \( h'(m) = 0 \).
and \( h'(m + 1) = i \neq 0 \). If \( P_{T,m} \) is propositionally unsatisfiable, then \( \neg S'(\overline{t}) \) is a t.c. of \( P_{T,m} \), and then \( i = 1 \leq \max\{j_0, m\} \). So, we may assume that \( P_{T,m} \) is propositionally satisfiable.

- Suppose that \( \neg S'(\overline{t}) \) is a t.c. of \( P_{T,m} \), then \( S'(\overline{t}) \) is a subformula of a formula contained in \( P_{T,m} \) because \( S'(\overline{t}) \) is propositionally atomic. Then, the Gödel number of \( S'(\overline{t}) \) is smaller than \( m \), and hence \( i \leq m \leq \max\{j_0, m\} \).

- Suppose that there exists a sentence \( \varphi \) such that \( \neg \varphi \notin P_{T,m} \cup X_{i,m} \) and \( S'(\overline{t}) \rightarrow \neg \varphi \) is a t.c. of \( P_{T,m} \).
  - If \( \neg \text{Pr}^R_{g_3}(\varphi) \) is a t.c. of \( P_{T,m} \), then so is \( S'(\overline{t}) \rightarrow \neg \text{Pr}^R_{g_3}(\varphi) \). Since \( A_e \) has no subformulas of the form \( \Box D \), we have that \( X_{j_0,m} = \emptyset \). So, \( \neg \varphi \notin P_{T,m} \cup X_{j_0,m} \). We obtain \( i \leq j_0 \leq \max\{j_0, m\} \).
  - If \( \neg \text{Pr}^R_{g_3}(\varphi) \) is not a t.c. of \( P_{T,m} \), then \( S'(\overline{t}) \) is a t.c. of the propositionally satisfiable set \( P_{T,m} \cup \{\text{Pr}^R_{g_3}(\varphi)\} \). Since \( S'(\overline{t}) \) is distinct from propositionally atomic \( \text{Pr}^R_{g_3}(\varphi) \), we have that \( S'(\overline{t}) \) is a subformula of a formula in \( P_{T,m} \) as above. We have \( i \leq m \leq \max\{j_0, m\} \).

We have shown \( i \leq \max\{j_0, m\} \). Moreover, the above argument can be carried out in \( \text{PA} \).

Secondly, we define the function \( g_3 \). We only give the definition of Procedure 2 of the construction of \( g_3 \).

**PROCEDURE 2**

Let \( m, i \neq 0 \), and \( n \) be such that \( h'(m) = 0 \), \( h'(m + 1) = i \), and \( i \in W_n \). Let \( \chi_0, \ldots, \chi_{k-1} \) be the listing of all elements of the set \( X_{i,m-1} \) arranged in descending order of Gödel numbers. For \( l < k \), define

\[
g_3(m + l) = \chi_l.
\]

And define

\[
g_3(m + k + t) = \xi_t.
\]

The definition of \( g_3 \) is finished. The construction of \( g_3 \) is exactly the same as that of \( g_2 \) in the proof of Theorem 6.4, except that it is based on the family of \( N \)-models corresponding to the logic \( \text{NR}4 \) and uses \( X_{i,m-1} \) and \( h' \) instead of \( X \) and \( h \), respectively.

Similarly to Proposition 4.3, the following claim holds.

**Claim 7.2.**

1. \( \text{PA} \vdash \forall x \forall y (0 < x < y \land S'(x) \rightarrow \neg S'(y)) \).
2. \( \text{PA} \vdash \neg \text{Con}_T \leftrightarrow \exists x (S'(x) \land x \neq 0) \).
3. For each \( i \in \omega \setminus \{0\} \), \( T \not\models \neg S'(\overline{t}) \).
4. For each \( n \in \omega \), \( \text{PA} \vdash \forall x \forall y (h'(x) = 0 \land h'(x + 1) = y \land y \neq 0 \rightarrow x > \pi) \).
Proof. 1. This is straightforward from the definition of $h'$.

2. The implication $\rightarrow$ is easy, and so we prove the implication $\leftarrow$. Argue in PA: Suppose that $S'(i)$ holds for some $i \neq 0$. Let $m$ and $n$ be such that $h'(m) = 0$, $h'(m + 1) = i$, and $i \in W_n$. Also, let $k$ be the cardinality of the set $X_{i,m-1}$. We would like to show that $T$ is inconsistent. We distinguish the following two cases:

- **Case 1:** $\neg S'(\tilde{i})$ is a t.c. of $P_{T,m}$.
  Then, $\neg S'(\tilde{i})$ is $T$-provable. Since $S'(\tilde{i})$ is a true $\Sigma_1$ sentence, it is provable in $T$. Therefore, $T$ is inconsistent.

- **Case 2:** There exists a $\varphi$ such that $\neg \varphi \notin P_{T,m} \cup X_{i,m}$ and $S'(\tilde{i}) \rightarrow \neg Pr_{g_3}(\varphi \gamma)$ is a t.c. of $P_{T,m}$.
  Then, $\neg \varphi \notin P_{T,m-1} \cup X_{i,m-1}$. Hence, $\neg \varphi \notin \{g_3(0), \ldots, g_3(m + k - 1)\}$. Let $s$ and $u$ be such that $\xi_s \equiv \varphi$ and $\xi_u \equiv \neg \varphi$. We have that $s < u$, $g_3(m + k + s) = \varphi$, and $g_3(m + k + u) = \neg \varphi$. In particular, $g_3(m + k + u)$ is the first output of $\neg \varphi$ by $g_3$. Hence, $Pr_{g_3}(\neg \varphi \gamma)$ holds. Then, $S'(\tilde{i}) \rightarrow \neg Pr_{g_3}(\neg \varphi \gamma)$ is a true $\Sigma_1$ sentence, and so it is provable in $T$. Since $S'(\tilde{i}) \rightarrow \neg Pr_{g_3}(\neg \varphi \gamma)$ is also provable in $T$, we have that $T$ is inconsistent.

3. Suppose $T \vdash \neg S'(\tilde{i})$ for $i \neq 0$. Let $p$ be a $T$-proof of $\neg S'(\tilde{i})$. Then, $\neg S'(\tilde{i}) \in P_{T,p}$, and thus $h'(p + 1) \neq 0$. This means that $\exists x(S'(x) \land x \neq 0)$ is true. By clause 2, $T$ is inconsistent, a contradiction.

4. Since $T$ is consistent, we have that $h'(m + 1) = 0$ for all $m \in \omega$ by clause 2. So, clause 4 is immediately obtained.

The following claim is proved as in the proof of Theorem 6.4.

**Claim 7.3.**

1. $\text{PA} + \text{Con}_T \vdash \forall x \forall y \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Proof}_T(x, y) \leftrightarrow x = g_3(y)) \right)$.

2. $\text{PA} \vdash \forall x \left( \text{Fml}_{\mathcal{L}_A}(x) \rightarrow (\text{Prov}_T(x) \leftrightarrow Pr_{g_3}(x)) \right)$.

Hence, $Pr_{g_3}(x)$ is a Rosser provability predicate of $T$.

**Claim 7.4.** Let $i \in W_n$ and $B \in \text{Sub}(A_n)$.

1. If $i \vdash_n B$, then $\text{PA} \vdash S'(\bar{i}) \rightarrow f_{g_3}(B)$.

2. If $i \nvdash_n B$, then $\text{PA} \vdash S'(\bar{i}) \rightarrow \neg f_{g_3}(B)$.

**Proof.** We prove the claim by induction on the construction of $B \in \text{Sub}(A_n)$. We only give a proof of the case $B \equiv \Box C$.

1. Suppose that $i \vdash_n \Box C$. For each $l \in W_n$ with $l \vdash_n C$, by the induction hypothesis, we have $\text{PA} \vdash S'(\bar{l}) \rightarrow f_{g_3}(C)$. Since $W_n$ is finite and the model $(W_n, \{\vdash_n, B\}_{B \in \text{MF}}, \vdash_n)$ is primitive recursively represented, we find a $p \in \omega$ such that

$$\text{PA} \vdash \forall x \in W_n (x \vdash_n C \rightarrow \exists y < p \text{Proof}_T(\neg S'(\bar{x}) \rightarrow f_{g_3}(C) \gamma, y)).$$

(2)
Since □C ∈ Sub(A_n) and (W_n, {<_n,B} B∈MF, ⊨n) is Sub(A_n)-serial, there exists a j ∈ W_n such that i ≺n,C j. Then, j ⊨n C and there exists a T-proof of S’(j) → f_{g_3}(C) smaller than p.

We argue in PA + S’(j): Let m be such that h’(m) = 0 and h’(m + 1) = i.

If ‾f_{g_3}(C) ∈ P_{T,m−1}, then S’(j) is a t.c. of P_{T,m−1} because m > p by Claim 7.2.4. We have h’(m) ≠ 0 by the definition of h’, and this is a contradiction. Hence, f_{g_3}(C) ⊈ P_{T,m−1}. If f_{g_3}(C) ∈ X_{i,m−1}, then there exist □D ∈ Sub(A_n) and l ∈ W_n such that f_{g_3}(C) = f_{g_3}(D), i ≺n,D l, and S’(l) → f_{g_3}(D) is a t.c. of P_{T,m−1}. We have C ⊆ D. Since i ⊨n □C and i ≺n,C l, we have l ⊨n C. By [1], we obtain that S’(l) → f_{g_3}(C) has a T-proof smaller than p. Since m > p by Claim 7.2.4, S’(j) → f_{g_3}(C) is in P_{T,m−1}. Since both S’(l) → f_{g_3}(C) and S’(l) → ‾f_{g_3}(C) are t.c.s of P_{T,m−1}, we have that S’(l) is a t.c. of P_{T,m−1}, a contradiction with h’(m) = 0. Thus, we have ‾f_{g_3}(C) ⊈ X_{i,m−1}, that is, ‾f_{g_3}(C) ⊈ {g_3(m), . . . , g_3(m + k − 1)}.

Therefore, we obtain ‾f_{g_3}(C) ⊈ {g_3(0), . . . , g_3(m + k − 1)}.

Let s and u be such that ξ_s = f_{g_3}(C) and ξ_u = ‾f_{g_3}(C). Then, s < u, g_3(m + k + s) = f_{g_3}(C), g_3(m + k + u) = ‾f_{g_3}(C), and this is the first g_3-output of ‾f_{g_3}(C). Therefore, Pr^{R}_{g_3}(^{-f_{g_3}(C)}) holds. That is, f_{g_3}(□C) holds.

2. Suppose i ≺n □C. There exists a j ∈ W_n such that i ≺n,C j and j ⊵n C. By the induction hypothesis, PA ⊨ S’(j) → ‾f_{g_3}(C). Let p be a T-proof of S’(j) → ‾f_{g_3}(C).

We reason in PA + S’(j): Let m be such that h’(m) = 0 and h’(m + 1) = i. Since m > p by Claim 7.2.4, S’(j) → f_{g_3}(C) is a t.c. of P_{T,m−1}, and hence we have ‾f_{g_3}(C) ∈ X_{i,m−1}. If f_{g_3}(C) ∈ P_{T,m−1}, then S’(j) is a t.c. of P_{T,m−1}, a contradiction. Hence, f_{g_3}(C) ⊈ {g_3(0), . . . , g_3(m + k − 1)}. Then, even if f_{g_3}(C) ∈ X_{i,m−1}, we get that g_3 outputs ‾f_{g_3}(C) earlier than any output of f_{g_3}(C). Hence, Pr^{R}_{g_3}(^{-f_{g_3}(C)}) holds. That is, ‾f_{g_3}(□C) holds.

We prove that Pr^{R}_{g_3}(x) satisfies D3.

Claim 7.5. For any L_A-formula ϕ, PA ⊨ Pr^{R}_{g_3}(^{-ϕ}) → Pr^{R}_{g_3}(^{-Pr^{R}_{g_3}(^{-ϕ})})).

Proof. Since Pr^{R}_{g_3}(^{-ϕ}) is a Σ_1 sentence, PA ⊨ Pr^{R}_{g_3}(^{-ϕ}) → Prov_T(Pr^{R}_{g_3}(^{-ϕ})) by Claim 7.3.1, we have

\[ PA + Con_T ⊨ ∀x \left( \text{Fml}_{L_A}(x) → ( Prov_T(x) ↔ Pr^{R}_{g_3}(x) ) \right). \]

Since PA + Con_T ⊨ ∀x \left( \text{Fml}_{L_A}(x) → ( Prov_T(x) ↔ Pr^{R}_{g_3}(x) ) \right), we obtain

\[ PA + Con_T ⊨ ∀x \left( \text{Fml}_{L_A}(x) → ( Prov_T(x) ↔ Pr^{R}_{g_3}(x) ) \right). \]

Thus,

\[ PA + Con_T ⊨ Pr^{R}_{g_3}(^{-ϕ}) → Pr^{R}_{g_3}(^{-Pr^{R}_{g_3}(^{-ϕ})}). \]

We reason in PA + ¬Con_T + ¬Pr^{R}_{g_3}(^{-Pr^{R}_{g_3}(^{-ϕ})})): By Claim 7.2.2, there exists an i ≠ 0 such that S’(i) holds. Let m and n be such that h’(m) = 0,
$h'(m + 1) = i$, and $i \in W_n$. If $\neg \varphi \in P_{T,m-1}$, then $\varphi \notin P_{T,m-1}$ because $\neg S(\overline{g})$ is not a t.c. of $P_{T,m-1}$ for all $j \neq 0$. In this case, $\neg P_{g_3}^{R}(\varphi)$ holds.

Therefore, in the following, we assume that $\neg \varphi \notin P_{T,m-1}$. Let $k$ be the cardinality of the set $X_{i,m-1}$. Since $\neg P_{g_3}^{R}(\varphi)$ holds, $\neg P_{g_3}^{R}(\varphi)$ is output by $g_3$ earlier than any output of $P_{g_3}^{R}(\varphi)$. Let $s$ and $u$ be such that $\xi_s \equiv P_{g_3}^{R}(\varphi)$ and $\xi_u \equiv \neg P_{g_3}^{R}(\varphi)$. Then, $g_3(m + k + u) = \neg P_{g_3}^{R}(\varphi)$. Since $s < u$ and $g_3(m + k + s) = P_{g_3}^{R}(\varphi)$, $g_3(m + k + u)$ is not the first output of $\neg P_{g_3}^{R}(\varphi)$. It follows that $\neg P_{g_3}^{R}(\varphi) \in P_{T,m-1} \cup X_{i,m-1}$. We would like to show that $\neg P_{g_3}^{R}(\varphi)$ holds. We distinguish the following two cases:

- **Case 1**: $\neg P_{g_3}^{R}(\varphi) \in P_{T,m-1}$.

  If $\neg \varphi \notin P_{T,m-1} \cup X_{i,m-1}$, then $0 \neq h'(m) \leq i$ because the Gödel number of $\varphi$ is smaller than $m - 1$ by Claim 7.2 and $S'(\overline{g}) \rightarrow \neg P_{g_3}^{R}(\varphi)$ is a t.c. of $P_{T,m-1}$. This is a contradiction. Hence, $\neg \varphi \notin P_{T,m-1} \cup X_{i,m-1}$. Since $\neg \varphi \notin P_{T,m-1}$ by the assumption, we have $\neg \varphi \in X_{i,m-1}$. Then, there exist $D \in \text{Sub}(A_n)$ and $l \in W_n$ such that $\neg \varphi \equiv f_{g_3}(D)$, $i \prec_{n,D} l$, and $S'(\overline{g}) \rightarrow f_{g_3}(D)$ is a t.c. of $P_{T,m-1}$. Since $S'(\overline{g}) \rightarrow \neg \varphi$ is a t.c. of $P_{T,m-1}$ but $S'(\overline{g})$ is not, we have $\varphi \notin P_{T,m-1}$. Thus, $\varphi \notin \{g_3(0), \ldots, g_3(m - 1)\}$. Then, even if $\varphi \in X_{i,m-1}$, $\neg \varphi$ is output by $g_3$ earlier than any output of $\varphi$. Therefore, $\neg P_{g_3}^{R}(\varphi)$ holds.

- **Case 2**: $\neg P_{g_3}^{R}(\varphi) \in X_{i,m-1}$.

  Then, there exist $D \in \text{Sub}(A_n)$ and $j \in W_n$ such that $\neg P_{g_3}^{R}(\varphi) \equiv \neg f_{g_3}(D)$, $i \prec_{n,D} j$, and $S'(\overline{g}) \rightarrow \neg f_{g_3}(D)$ is a t.c. of $P_{T,m-1}$. It follows that $P_{g_3}^{R}(\varphi) \equiv f_{g_3}(D)$. By the definition of $f_{g_3}$, there exists a $E \in \text{Sub}(A_n)$ such that $D \equiv \square E$ and $P_{g_3}(\varphi) \equiv P_{g_3}(\neg f_{g_3}(E))$. We have that $\varphi \equiv f_{g_3}(E)$, $\square E \in \text{Sub}(A_n)$, and $i \prec_{n,D} E j$.

  If $\neg f_{g_3}(E) \notin X_{i,m-1}$, then $\neg f_{g_3}(E) \notin P_{T,m-1} \cup X_{i,m-1}$ by the assumption. Since the Gödel number of $f_{g_3}(E)$ is smaller than $m - 1$ and $S'(\overline{g}) \rightarrow \neg P_{g_3}^{R}(\neg f_{g_3}(E))$ is a t.c. of $P_{T,m-1}$, we have $h'(m) \neq 0$. This is a contradiction. Hence, $\neg f_{g_3}(E) \in X_{i,m-1}$. Then, there exists an $l \in W_n$ such that $i \prec_{n,E} l$ and $S'(\overline{g}) \rightarrow \neg f_{g_3}(E)$ is a t.c. of $P_{T,m-1}$. Since $i \prec_{n,E} j$ and $j \prec_{n,E} l$, we obtain $i \prec_{n,E} l$ because $(W_n, \{x_n, B \mid B \in MF, i \in n\})$ is transitive. Therefore, $\neg f_{g_3}(E) \in X_{i,m-1}$, and hence $\neg \varphi \in X_{i,m-1}$.

  Since $S'(\overline{g}) \rightarrow \neg \varphi$ is a t.c. of $P_{T,m-1}$, we have $\varphi \notin P_{T,m-1}$. Hence, $\varphi \notin \{g_3(0), \ldots, g_3(m - 1)\}$. Then, even if $\varphi \in X_{i,m-1}$, $g_3$ outputs $\neg \varphi$ earlier than any output of $\varphi$. Therefore, $\neg P_{g_3}(\varphi)$ holds.

We have proved $PA + \neg \text{Con}_T \vdash P_{g_3}(\neg \varphi) \rightarrow P_{g_3}^{R}(\neg \varphi)$, $\neg P_{g_3}(\varphi)$. By the law of excluded middle, $PA \vdash P_{g_3}(\varphi) \rightarrow P_{g_3}^{R}(\neg \varphi)$. The first clause of the theorem follows from Claims 7.3 and 7.5. The second clause follows from Claims 7.2 and 7.4.
Corollary 7.6.

\[ \text{NR4} = \bigcap \{ \text{PL}(\Pr^R_T) \mid \Pr^R_T(x) \text{ is a Rosser provability predicate of } T \text{ satisfying D3} \} \]

Moreover, there exists a Rosser provability predicate \( \Pr^R_T(x) \) of \( T \) such that \( \text{NR4} = \text{PL}(\Pr^R_T) \).

A Appendix: \( \Sigma_1 \) provability predicates corresponding to \( K \)

In [9], it is proved that there exists a \( \Sigma_2 \) provability predicate \( \text{Pr}_T(x) \) of \( T \) such that \( K = \text{PL}(\text{Pr}_T) \). It follows

\[
K = \bigcap \{ \text{PL}(\text{Pr}_T) \mid \text{Pr}_T(x) \text{ is a provability predicate of } T \text{ satisfying } D2 \}.
\]

As in Theorems 4.2 and 5.1, we prove that the provability logic of all \( \Sigma_1 \) provability predicates satisfying \( D2 \) is also \( K \).
Theorem A.1 (The uniform arithmetical completeness of $K$). There exists a $\Sigma_1$ provability predicate $Pr_T(x)$ of $T$ such that

1. for any $A \in MF$ and any arithmetical interpretation $f$ based on $Pr_T(x)$, if $K \vdash A$, then $PA \vdash f(A)$; and

2. there exists an arithmetical interpretation $f$ based on $Pr_T(x)$ such that for any $A \in MF$, $K \vdash A$ if and only if $T \vdash f(A)$.

Proof. Let $(W, \prec, \models)$ be a primitive recursively representable Kripke model satisfying the following conditions:

- $W = \omega \setminus \{0\}$,
- $(W, \prec, \models)$ is the disjoint union of finite Kripke models and for every $i \in W$, we can primitive recursively find the finite set $\{j \in W \mid i \prec j\}$ that may be empty,
- for any $K$-unprovable $\mathcal{L}(\Box)$-formula $A$, there exists an $i \in W$ such that $i \not\models A$.

We define the primitive recursive function $g_4$ corresponding to this theorem. We only describe Procedure 2.

**Procedure 2**

Let $m$ and $i \neq 0$ be such that $h(m) = 0$ and $h(m + 1) = i$. Define

$$g_4(m + t) = \begin{cases} \xi_t & \text{if } \xi_t \text{ is a t.c. of } P_{T,m-1} \cup \{\bigvee_{i \triangleleft j} S(j)\}, \\ 0 & \text{otherwise.} \end{cases}$$

Notice that the empty disjunction represents $0 = 1$. Our definition of $g_4$ is finished. Let $f_{g_4}$ be the arithmetical interpretation based on $Pr_{g_4}(x)$ defined by $f_{g_4}(p) \equiv \exists x(S(x) \land x \neq 0 \land x \models p)$.

The following claim is proved similarly as in the proof of Theorem 4.2.

**Claim A.2.** $PA + Con_T \vdash \forall x \forall y \left( \text{Fml}_{\mathcal{L}_A}(x) \to (Proof_T(x,y) \iff x = g_4(y)) \right)$.

Thus, $Pr_{g_4}(x)$ is a $\Sigma_1$ provability predicate of $T$.

**Claim A.3.** $PA$ proves the following statement: “Let $m$ and $i \neq 0$ be such that $h(m) = 0$ and $h(m + 1) = i$. Then, for any $\mathcal{L}_A$-formula $\varphi$, $Pr_{g_4}(\varphi \rightarrow \varphi)$ holds $\iff$ $\varphi$ is a t.c. of $P_{T,m-1} \cup \{\bigvee_{i \triangleleft j} S(j)\}$.”

**Proof.** ($\Rightarrow$): This is because if $\xi_t \in P_{T,m-1}$, then $\xi_t$ is a t.c. of $P_{T,m-1} \cup \{\bigvee_{i \triangleleft j} S(j)\}$.

($\Leftarrow$): Immediate from the definition of $g_4$. \[\square\]

**Claim A.4.** $PA \vdash \forall x \forall y (Pr_{g_4}(x \rightarrow y) \land Pr_{g_4}(x) \rightarrow Pr_{g_4}(y))$. 31
Proof. Since $\text{PA} \vdash \forall x \forall y (\text{Prov}_T(x \rightarrow y) \land \text{Prov}_T(x) \rightarrow \text{Prov}_T(y))$, we have $\text{PA} + \text{Con}_T \vdash \forall x \forall y (\text{Pr}_{g_A}(x \rightarrow y) \land \text{Pr}_{g_A}(x) \rightarrow \text{Pr}_{g_A}(y))$ by Claim A.2.

We argue in $\text{PA} + \neg \text{Con}_T$: By Proposition 4.3.2, there exists an $i \neq 0$ such that $S(i)$ holds. Let $m$ be such that $h(m) = 0$ and $h(m + 1) = i$. Suppose $\text{Pr}_{g_A}(\neg \varphi \rightarrow \psi)$ and $\text{Pr}_{g_A}(\neg \varphi \land \varphi)$ hold. By Claim A.3, both $\varphi \rightarrow \psi$ and $\varphi$ are t.c.’s of $P_{T,m-1} \cup \{V_{i,j} S(j)\}$. We have that $\psi$ is also a t.c. of $P_{T,m-1} \cup \{V_{i,j} S(j)\}$. By Claim A.3 again, we obtain that $\text{Pr}_{g_A}(\neg \psi \land \varphi)$ holds.

We have proved $\text{PA} + \neg \text{Con}_T \vdash \forall x \forall y (\text{Pr}_{g_A}(x \rightarrow y) \land \text{Pr}_{g_A}(x) \rightarrow \text{Pr}_{g_A}(y))$. By the law of excluded middle, we conclude $\text{PA} \vdash \forall x \forall y (\text{Pr}_{g_A}(x \rightarrow y) \land \text{Pr}_{g_A}(x) \rightarrow \text{Pr}_{g_A}(y))$. 

Claim A.5. Let $i, l \in W$.

1. $\text{PA} \vdash S(i) \rightarrow \text{Pr}_{g_A}(\neg V_{i,j} S(j))$.

2. If $i < l$, then $\text{PA} \vdash S(i) \rightarrow \neg \text{Pr}_{g_A}(\neg S(l))$.

Proof. We proceed in $\text{PA} + S(i)$: Let $m$ be such that $h(m) = 0$ and $h(m + 1) = i$.

1. Since $V_{i,j} S(j)$ is a t.c. of $P_{T,m-1} \cup \{V_{i,j} S(j)\}$, it follows that $\text{Pr}_{g_A}(\neg V_{i,j} S(j))$ holds by Claim A.3.

2. Suppose, towards a contradiction, that $\neg S(l)$ is a t.c. of $P_{T,m-1} \cup \{V_{i,j} S(j)\}$. Then, $\text{Pr}_{g_A}(\neg V_{i,j} S(j)) \rightarrow \neg S(l)$ is a t.c. of $P_{T,m-1}$. Since $S(l)$ is a disjunct of $V_{i,j} S(j)$, $\neg S(l)$ is also a t.c. of $P_{T,m-1}$. We have that $\neg S(l)$ is a t.c. of $P_{T,m-1}$. This is a contradiction. Hence, $\neg S(l)$ is not a t.c. of $P_{T,m-1} \cup \{V_{i,j} S(j)\}$. By Claim A.3, $\neg \text{Pr}_{g_A}(\neg S(l))$ holds.

The following claim is proved in the same fashion as in the usual proof of Solovay’s arithmetical completeness theorem by using Claim A.5.

Claim A.6. Let $i \in W$ and $B \in \text{MF}$.

1. If $i \models B$, then $\text{PA} \vdash S(i) \rightarrow f_{g_A}(B)$.

2. If $i \not\models B$, then $\text{PA} \vdash S(i) \rightarrow \neg f_{g_A}(B)$.

The first clause of Theorem A.1 follows from Claims A.2 and A.4. The second clause follows from Proposition 4.3.3 and Claim A.6.

Corollary A.7.

$K = \bigcap \{\text{PL} \mid \text{Pr}_T(x) \text{ is a } \Sigma_1 \text{ provability predicate of } T \text{ satisfying D2}\}$.

Moreover, there exists a $\Sigma_1$ provability predicate $\text{Pr}_T(x)$ of $T$ such that $K = \text{PL} \text{ of } T$.
Appendix: Interchangeability of □ and ◊ in NR

The language of propositional modal logic does not have the symbol ◊ as a modal operator. We introduce the expression ◊A as the abbreviation of ◊¬◊¬A. However, in the logic N, □ and ◊ are not dual operators, that is, we show that ◊¬¬p ↔ □p is not provable in NR4.

Proposition B.1. NR4 ⊬ ◊¬¬p → □p.

Proof. Let F = ({a, b}, {≺B}B∈MF) be the N-frame defined as follows: for each B ∈ MF and x, y ∈ {a, b},

\[
x ≺B y \iff \begin{cases} 
  y = b & \text{if } B ∼ p, \\
  x = y & \text{otherwise.}
\end{cases}
\]

Obviously, F is serial. We prove that F is transitive. Suppose x ≺B y ≺B z for B ∈ MF and x, y, z ∈ {a, b}. Since □B ∼ p, we have x = y. Thus, we obtain x ≺B z because y ∼B z.

Let ⊩ be a satisfaction relation on F such that a ⊩ p and b ⊭ p. Since ¬¬p ∼ p, we have that a ≺¬¬p x if and only of x = a. So, we obtain a ⊩ □¬¬p because a ⊩ ¬¬p. Since a ⊩ ¬¬¬□¬¬p, we get a ⊩ ¬¬¬p. On the other hand, we have a ⊭ □¬¬p because a ≺¬¬¬p, b and b ⊭ □¬¬p. Therefore, ¬◊¬¬p → □p is not valid in F. By Corollary 3.10, we conclude that NR4 ⊬ ◊¬¬p → □p.

From another point of view, in NR, the operators □ and ◊ have an interesting relationship. That is, in a sense, □ and ◊ are interchangeable in NR. To state this fact precisely, we introduce the following translation χ.

Definition B.2. We define a translation χ of L(□)-formulas recursively as follows:

1. χ(A) is A if A is a propositional variable or ⊥,
2. χ(¬A) is ¬χ(A),
3. χ(A ◦ B) is χ(A) ◦ χ(B) for ◦ ∈ {∧, ∨, →},
4. χ(□A) is ◊χ(A).

That is, χ(A) is obtained from A by replacing every □ with ◊.

Proposition B.3. For any A ∈ MF, NR ⊬ A if and only if NR ⊬ χ(A).

Proof. (⇒): We prove this implication by induction on the length of proofs in NR. It suffices to prove that NR is closed under the rules \(\frac{A}{◊A}\) and \(\frac{◊A}{¬◊A}\).

Suppose NR ⊬ A. Then, NR ⊬ ¬¬A. By the rule ROS, NR ⊬ ¬◊¬A, that is, NR ⊬ ◊A.
Suppose $\textbf{NR} \vdash \neg A$. By \textbf{Nec}, $\textbf{NR} \vdash \Box \neg A$, and then $\textbf{NR} \vdash \neg \Box \neg A$. This means $\textbf{NR} \vdash \neg \Diamond A$.

$(\Leftarrow)$: We prove the contrapositive. Suppose $\textbf{NR} \not\vdash A$. Then, by Theorem 3.12 there exists a serial $\textbf{N}$-model $\mathcal{M} = (W, \{ \prec\prec_B \}_{B \in \text{MF}}, \models)$ and $w \in W$ such that $w \not\models A$. For each $B \in \text{MF}$, let $\prec\prec_B^*$ be the binary relation on $W$ defined as follows:

$$
\prec\prec_B^* := \begin{cases} 
\prec_B & \text{if } B \text{ is of the form } \neg\neg \chi(\chi(D)), \\
\prec_D & \text{otherwise}.
\end{cases}
$$

Let $\mathcal{M'}$ be the $\textbf{N}$-model $(W, \{ \prec\prec_B^* \}_{B \in \text{MF}}, \models^*)$ defined by $x \models^* p : \iff x \models p$. It is easy to see that the frame of $\mathcal{M'}$ is also serial.

**Claim B.4.** For any $\mathcal{L}(\Box)$-formula $C$ and $x \in W$, $x \models^* \chi(\chi(C))$ if and only if $x \models C$.

**Proof.** This claim is proved by induction on the construction of $C$. If $C$ is a propositional variable, the claim is trivial because $\chi(\chi(p))$ is exactly $p$. The cases of $\bot$ and propositional connectives are easy.

We prove the case that $C$ is of the form $\Box D$. Notice $\prec\prec_{\neg\neg \chi(\chi(D))} = \prec_D$. By the induction hypothesis, for any $y \in W$, $y \models^* \chi(\chi(D))$ if and only if $y \models D$.

$$
x \models^* \chi(\chi(D)) \iff x \models^* \Box \neg\neg \chi(\chi(D)),
\iff \forall y \in W (x \prec\prec_{\neg\neg \chi(\chi(D))} y \Rightarrow y \models^* \neg\neg \chi(\chi(D))),
\iff \forall y \in W (x \prec_D y \Rightarrow y \models^* \chi(\chi(D))),
\iff \forall y \in W (x \prec_D y \Rightarrow y \models D),
\iff x \models \Box D.
\qed
$$

Since $w \not\models A$, we obtain $w \not\models^* \chi(\chi(A))$ by Claim B.4. By Theorem 3.12 again, we obtain $\textbf{NR} \not\vdash \chi(\chi(A))$. Since we have already proved the implication ($\Rightarrow$) of the proposition, we conclude $\textbf{NR} \not\vdash \chi(A)$.  

\[34\]
