Abstract
In the present paper we study the asymptotic behavior of discretized finite dimensional dynamical systems. We prove that under some discrete angle condition and under a Lojasiewicz’s inequality condition, the solutions to an implicit scheme converge to equilibria points. We also present some numerical simulations suggesting that our results may be extended under weaker assumptions or to infinite dimensional dynamical systems.

Mathematics Subject Classification 2010 (MSC2010): 65K05, 65L20, 90C26, 37N40, 26E05, 40A05.

Key words: descent methods, real analytic functions, Lojasiewicz gradient inequality, single limit-point convergence, stability, convergence rates.
1 Introduction

A question that naturally issues when considering the study of the asymptotic behavior of dynamical systems is whether noticeable differences arise between continuous models and their discretizations. This is of course of main interests from the mathematical point of view, but it is also very common to introduce continuous models as a limit of a, say, physical model with low or very large scales of unknowns interactions involved. In this paper, what we have in mind lies indeed in the discretization of a nonlinear wave equation with a (here nonlocal) nonlinear part for which we give some numerical simulations in part 5.3. Having settled this, by means of an implicit discretization in time, the major results of this paper deal in fact with the asymptotic behavior of a discretized version of the following second order differential equation

\[ \ddot{x} + |\dot{x}|^{\alpha} \dot{x} + \nabla F(x) = 0, \]

for some real-valued function \( F \) and \( \alpha \geq 0 \). Different discretizations may be considered. We will here focus on an implicit discretization, in the spirit of the famous paper [1] in which the main results' angular stone is given by the inequality (4) satisfied by a sequence \((x_n)\). For such a sequence, the main results of the present paper, theorems 2.1 and 4.7 state that, on the one hand provided a Lojasiewicz inequality is satisfied as well as, on the other hand, the inequality (7), the convergence of this sequence occurs and the speed of convergence is estimated. This inequality (7) finds its origin in a more abstract inequality namely the so-called “angle condition” for continuous systems, which we describe further in this section. Though it is not stated this way in [1], the results therein have been considered by the authors in [18] to be more dedicated to explicit euler schemes, while in [18] an implicit scheme is considered for gradient-systems. The same implicit situation has been independently considered in [4]. In order to illustrate our results, some numerical simulations given in section 5 are presented with assumptions to comply (7), as well as more general situations which incline to think that the results given in section 4 may be extended.

Semi-implicit schemes are also considered in the present paper in section 5 leading also to think that our results may be also extended to this type of scheme.

Concerning the above evocated nonlinear partial differential evolution equation, with a non-local Hölder norm, rewritten in an abstract form equivalent to (1), we also performed some computations. For these, we used an implicit scheme in time together with a finite element method in space (here the space dimension is 1). The results that we obtain therein are in a way consistent with the asymptotic behaviour of solutions of (1) as given in [11], [12].

Let us briefly recall about the angle condition. We consider

\[ \dot{u}(t) + \mathcal{F}(u(t)) = 0, \quad t \geq 0, \]

where \( \mathcal{F} \in C(\mathbb{R}^p; \mathbb{R}^p) \). Let \( \mathcal{E} \in C^1(\mathbb{R}^p; \mathbb{R}) \). One says that \( \mathcal{E}' \) and \( \mathcal{F} \) satisfy an angle condition if there exists \( \alpha > 0 \) such that

\[ \langle \mathcal{E}'(u), \mathcal{F}(u) \rangle \geq \alpha \| \mathcal{E}'(u) \| \| \mathcal{F}(u) \| \quad \text{for every } u \in \mathbb{R}^p. \]
This condition appeared first in [1] in order to study (2) and discrete systems. It is clear that (1) can be written in the form (2). Chill et al. used in [8] this angle condition to study the behavior of solutions of (1) when \( \alpha = 0 \). More recently, Haraux and Jendoubi generalized in [10] the angle condition by adding a power \( \beta \) to \( \|E'(u)\| \) in order to deal with the equation (1) when \( \alpha \neq 0 \). In the situation when one studies discrete systems, as we already said some ”discrete” angle conditions have been considered. To our knowledge, the first one appeared in [1] and requires that the studied sequence \((x_n)\) satisfies the explicit form:

\[
\Phi(x_n) - \Phi(x_{n+1}) \geq \sigma \|\nabla \Phi(x_n)\| \|x_{n+1} - x_n\|,
\]

where \( \Phi \) is a real-valued function and \( \sigma > 0 \). It would be also worth to study the situation when

\[
\Phi(x_n) - \Phi(x_{n+1}) \geq \sigma \|\nabla \Phi(x_{n+1})\| \|x_{n+1} - x_n\|.
\]

The question of convergence under this last hypothesis instead of (4) is open to our best knowledge. Alaa and Pierre studied in [2] the convergence under the following assumption

\[
\Phi(x_n) - \Phi(x_{n+1}) \geq \sigma [\|\nabla \Phi(x_{n+1})\|^2 + \|x_{n+1} - x_n\|^2].
\]

It is straightforward to see that a sequence satisfying (6) also complies to (5).

In this paper we try to extend the results in [2] by considering (7).

\[2\] Main results of the paper

Let \( \Phi : \mathbb{R}^N \rightarrow \mathbb{R} \) be a \( C^1 \) function, \( \sigma > 0 \), \( \beta \geq 1 \) and let us consider a sequence \((x_n)\) satisfying

\[
\Phi(x_n) - \Phi(x_{n+1}) \geq \sigma [\|\nabla \Phi(x_{n+1})\|^\beta + \|x_{n+1} - x_n\|^{\beta+1}].
\]

**Theorem 2.1.** We assume that there exists \( \theta \in (0, \frac{1}{2}] \) such that

\[
\forall a \in \mathbb{R}^N \exists c_a > 0 \exists r_a > 0 / \forall u \in \mathbb{R}^N : \|x - a\| < r_a \implies \|\nabla \Phi(x)\| \geq c_a |\Phi(x) - \Phi(a)|^{1-\theta}.
\]

Assume also that

\[
\beta(1 - \theta) < 1.
\]

Let \((x_n)\) be a sequence satisfying (7). Then either \( \lim_{n \to +\infty} \|x_n\| = +\infty \), or there exists \( x^\infty \in \mathbb{R}^N \) such that \( \nabla \Phi(x^\infty) = 0 \) and

\[
\lim_{n \to +\infty} x_n = x^\infty.
\]

Precisely, in this case we have

\[
\|x_n - x^\infty\| = \begin{cases}
O(e^{-cn}) & \text{for some } c > 0 \text{ if } \beta = \frac{\theta}{1-\theta} \\
O(n^{-\frac{1-\beta(1-\theta)}{1-\theta}}) & \text{if } \beta > \frac{\theta}{1-\theta}.
\end{cases}
\]
Remark 2.2. Let us note that since $\beta \geq 1$ and $\theta \in (0, \frac{1}{2}]$, then $\beta(1 - \theta) \geq \theta$. Let us also remark that the equality $\beta = \frac{\theta}{1-\theta}$ requires $\beta = 1$ and $\theta = \frac{1}{2}$.

Remark 2.3. If there exists $M > 0$ such that $\forall n \in \mathbb{N}, \|x_n\| \leq M$, then the hypothesis (8) may merely apply to those $a \in \mathbb{R}^N$ such that $\|a\| \leq M$.

Remark 2.4. By using Young’s inequality, one checks that the sequence $(x_n)$ defined by (7) satisfies

$$\Phi(x_n) - \Phi(x_{n+1}) \geq \sigma \frac{\beta + 1}{\beta} \|\nabla \Phi(x_{n+1})\|^{\beta} \|x_{n+1} - x_n\|^\beta.$$

(11)

Remark 2.5. Even in the case $\beta = 1$ (see remark 2.7 page 1296 of [2]) counterexamples to the convergence may occur either in the discrete or the continuous case. For the continuous case, one may refer to [17, 14], while for the discrete situation one may refer to [1].

3 Proof of Theorem 2.1

If $\lim_{n \to +\infty} \|x_n\| \neq +\infty$ the sequence $(x_n)$ has a bounded subsequence. Let $x^\infty$ be an accumulation point of the sequence. Since $(\Phi(x_n))$ is a non-increasing sequence, $\lim_{n \to +\infty} \Phi(x_n) = \Phi(x^\infty)$. Assume that for some $n_0 \in \mathbb{N}, \Phi(x_{n_0}) = \Phi(x^\infty)$, then for all $n \geq n_0$, $\Phi(x_n) = \Phi(x_{n_0})$.

According to (7), $x_n = x_{n_0}$ for all $n \geq n_0$.

Otherwise, for all $n \in \mathbb{N}$, one has $\Phi(x_n) > \Phi(x^\infty)$.

According to (8), we get

$$\exists c_0 > 0 \exists r > 0 / \forall x \in \mathbb{R}^n : \|x - x^\infty\| < r \implies \|\nabla \Phi(x)\| \geq c_0 |\Phi(x) - \Phi(x^\infty)|^{1-\theta}.$$  \quad (12)

In the sequel, without loss of generality, we assume $\Phi(x^\infty) = 0$.

Since $x^\infty$ is an accumulation point of $(x_n)$, there exists $n_1 \in \mathbb{N}$ such that

$$\left(\frac{1}{\sigma}\right)^{\frac{1}{\beta + 1}} [\Phi(x_{n_1})]^{\frac{1}{\beta + 1}} < \frac{r}{3}.$$ \quad (13)

$$\|x_{n_1} - x^\infty\| < \frac{r}{3}, \quad \text{and} \quad c_1 [\Phi(x_{n_1})]^{1-\beta(1-\theta)} + c_2 [\Phi(x_{n_1})]^{\frac{1}{\beta + 1}} < \frac{r}{3},$$ \quad (14)

where

$$c_1 = \frac{2^{\beta(1-\theta)\beta}}{(1 - \beta(1 - \theta))\sigma(\beta + 1)c_0^\beta}, \quad c_2 = \frac{1}{\sigma^{\frac{1}{\beta + 1}}} \frac{2^{\frac{1}{\beta + 1}}}{2^{\frac{1}{\beta + 1}} - 1}.$$ \quad (15)

Let $K = \sup\{n \geq n_1 / \forall i \in [n_1, n + 1], \|x_i - x^\infty\| < r\}$, and assume that $K < +\infty$.

Let us note that

$$\forall n \in [n_1 - 1, K] \|x_{n+1} - x^\infty\| < r.$$  \quad (16)

Let $n \in [n_1, K]$. As in [18, 2] we distinguish two cases.

First case, we assume that

$$\Phi(x_{n+1}) > \frac{\Phi(x_n)}{2}.$$  \quad (16)
We have
\[
\left[\Phi(x_n)\right]^{1-\beta(1-\theta)} - \left[\Phi(x_{n+1})\right]^{1-\beta(1-\theta)} = \int_{\Phi(x_n)}^{\Phi(x_{n+1})} (1 - \beta(1 - \theta)) x^{-\beta(1-\theta)} \, dx \\
\geq (1 - \beta(1 - \theta)) [\Phi(x_n) - \Phi(x_{n+1})] [\Phi(x_n)]^{-\beta(1-\theta)} \\
\geq 2^{-\beta(1-\theta)} (1 - \beta(1 - \theta)) [\Phi(x_n) - \Phi(x_{n+1})] [\Phi(x_n)]^{-\beta(1-\theta)} \quad \text{(by (16))} \\
\geq 2^{-\beta(1-\theta)} (1 - \beta(1 - \theta)) \sigma \frac{\beta + 1}{\beta} \|x_{n+1} - x_n\| \|\nabla \Phi(x_{n+1})\| \|\Phi(x_{n+1})\|^{-\beta(1-\theta)} \quad \text{(by (11))} \\
\geq 2^{-\beta(1-\theta)} (1 - \beta(1 - \theta)) \sigma \frac{\beta + 1}{\beta} c_0 \|x_{n+1} - x_n\| \quad \text{(by (12)).}
\]

For the second case, we assume that
\[
\Phi(x_{n+1}) \leq \frac{\Phi(x_n)}{2}. \quad \text{(17)}
\]

From (7), we get
\[
\|x_{n+1} - x_n\| \leq \frac{1}{\sigma^{\frac{1}{\beta+1}}} [\Phi(x_n) - \Phi(x_{n+1})]^{\frac{1}{\beta+1}} \\
\leq \frac{1}{\sigma^{\frac{1}{\beta+1}}} [\Phi(x_n)]^{\frac{1}{\beta+1}} \\
\leq \frac{1}{\sigma^{\frac{1}{\beta+1}}} \frac{2^{\frac{1}{\beta+1}}}{2^{\frac{1}{\beta+1}} - 1} \left( [\Phi(x_n)]^{\frac{1}{\beta+1}} - [\Phi(x_{n+1})]^{\frac{1}{\beta+1}} \right) \quad \text{by (17)}
\]

In both cases we have for all \( n \in [n_1, K] \)
\[
\|x_{n+1} - x_n\| \leq c_1 \left( [\Phi(x_n)]^{1-\beta(1-\theta)} - [\Phi(x_{n+1})]^{1-\beta(1-\theta)} \right) + c_2 \left( [\Phi(x_n)]^{\frac{1}{\beta+1}} - [\Phi(x_{n+1})]^{\frac{1}{\beta+1}} \right), \quad \text{(18)}
\]
where \(c_1\) and \(c_2\) are defined in (15).

Now we have
\[
\|x_{K+2} - x_\infty\|
\leq \|x_{K+2} - x_{K+1}\| + \|x_{K+1} - x_\infty\|
\leq \left(\frac{1}{\sigma}\right)^{\frac{1}{\beta+1}} \left[\Phi(x_{K+1}) - \Phi(x_{K+2})\right]^{\frac{1}{\beta+1}} + \|x_{K+1} - x_\infty\| \quad \text{(by (7))}
\]
\[
\leq \left(\frac{1}{\sigma}\right)^{\frac{1}{\beta+1}} \left[\Phi(x_{n_1})\right]^{\frac{1}{\beta+1}} + \|x_{K+1} - x_\infty\|
\]
\[
\leq \frac{r}{3} + \|x_{K+1} - x_\infty\| \quad \text{(by (13))}
\]
\[
\leq \frac{r}{3} + \|x_{K+1} - x_{n_1}\| + \|x_{n_1} - x_\infty\|
\]
\[
\leq \frac{r}{3} + \sum_{k=n_1}^{K} \|x_{k+1} - x_k\| + \frac{r}{3} \quad \text{(by (13))}
\]
\[
\leq c_1 \left(\left[\Phi(x_{n_1})\right]^{1-\beta(1-\theta)} - \left[\Phi(x_{K+1})\right]^{1-\beta(1-\theta)}\right) + c_2 \left(\left[\Phi(x_{n_1})\right]^{\frac{1}{\beta+1}} - \left[\Phi(x_{K+1})\right]^{\frac{1}{\beta+1}}\right) + \frac{2r}{3}
\]
\[
\leq c_1 \left(\left[\Phi(x_{n_1})\right]^{1-\beta(1-\theta)} + c_2 \left[\Phi(x_{n_1})\right]^{\frac{1}{\beta+1}} \right) + \frac{2r}{3}
\]
\[
< r \quad \text{(by (14))}
\]

which contradicts the definition of \(K\). Thus \(K = \infty\) and (18) is true for all \(n \geq n_1\). So \(\sum \|x_{n+1} - x_n\|\) converges and so the sequence \((x_n)\).

We now will prove (10). We proved (see (18)) that for all \(p \geq n_1\)
\[
\|x_{p+1} - x_p\|
\leq c_1 \left(\left[\Phi(x_{p})\right]^{1-\beta(1-\theta)} - \left[\Phi(x_{p+1})\right]^{1-\beta(1-\theta)}\right) + c_2 \left(\left[\Phi(x_{p})\right]^{\frac{1}{\beta+1}} - \left[\Phi(x_{p+1})\right]^{\frac{1}{\beta+1}}\right).
\]

For any \(n \geq n_1\), there holds
\[
\|x_n - x_\infty\| \leq \sum_{p=n}^{\infty} \|x_{p+1} - x_p\|
\leq c_1 \left[\Phi(x_{n})\right]^{1-\beta(1-\theta)} + c_2 \left[\Phi(x_{n})\right]^{\frac{1}{\beta+1}}
\]

If there exists \(n_2 \geq n_1\) such that \(\Phi(x_{n_2}) = 0\), since \(\Phi(x_n)\) is non-increasing, then for all \(n \geq n_2\), \(\Phi(x_n) = 0\). Using (7), it comes \(x_n = x_\infty\) for all \(n \geq n_2\). Otherwise, in order to estimate the speed of convergence, we will adopt the related method in [18, 2]. See also [12, 5, 10, 13] where the speed of convergence is given in the continuous case.

Without loss of generality one may assume that \(\Phi(x_n) \leq 1\) for all \(n \geq n_1\). From (19), it comes
\[
\|x_n - x_\infty\| \leq \left\{ \begin{array}{ll}
(c_1 + c_2)[\Phi(x_n)]^{\frac{1}{\beta+1}}, & \text{if} \ \beta(1-\theta) = \theta, \\
(c_1 + c_2)[\Phi(x_n)]^{\frac{1-\beta(1-\theta)}{\beta+1}}, & \text{if} \ \beta(1-\theta) > \theta.
\end{array} \right.
\]

(20)
Note that if $\beta(1 - \theta) = \theta$ then $\frac{1}{1+\beta} = 1 - \theta$.

For all $n \geq n_1$, there holds $\|x_n - x^\infty\| < r$, so that according to (12), one has

$$\|\nabla \Phi(x_n)\| \geq c_0 \Phi(x_n)^{1-\theta}. \quad (21)$$

Let

$$G : (0, +\infty) \rightarrow (0, +\infty)$$

$$s \mapsto G(s) = \begin{cases} 
-\ln(s) & \text{if } \beta = \frac{\theta}{1-\theta} \\
\frac{1}{\beta(1-\theta)-\theta s} & \text{if } \beta > \frac{\theta}{1-\theta}.
\end{cases}$$

For all $n \geq n_1$, one has

$$G(\Phi(x_{n+1})) - G(\Phi(x_n)) = \int_{\Phi(x_{n+1})}^{\Phi(x_n)} \frac{ds}{s^{(1-\theta)(1+\beta)}}$$

$$\geq \frac{\Phi(x_n) - \Phi(x_{n+1})}{\Phi(x_n)^{(1-\theta)(1+\beta)}}$$

$$\geq \sigma \|\nabla \Phi(x_n)\|^{1+\beta}$$

(by (7))

$$\geq c_0^{1+\beta} \sigma \quad \text{(by (21)).}$$

We therefore get

$$\forall n \geq n_1 \quad G(\Phi(x_n)) - G(\Phi(x_{n_1})) \geq c_0^{1+\beta} \sigma (n - n_1). \quad (22)$$

Now if we assume that $\beta = \frac{\theta}{1-\theta}$, we get

$$\forall n \geq n_1 \quad -\ln(\Phi(x_n)) + \ln(\Phi(x_{n_1})) \geq c_0^{1+\beta} \sigma (n - n_1),$$

or

$$\forall n \geq n_1 \quad \Phi(x_n) \leq (\Phi(x_{n_1})) e^{-c_0^{1+\beta} \sigma (n - n_1)}.$$

Thus, from (20), it comes

$$\forall n \geq n_1 \quad \|x_n - x^\infty\| \leq [\Phi(x_{n_1})]^{1-\theta} e^{-c_0^{1+\beta} \sigma (1-\theta)(n - n_1)}.$$

Likewise if $\beta > \frac{\theta}{1-\theta}$, we infer from (22)

$$\forall n \geq n_1 \quad G(\Phi(x_n)) \geq c_0^{1+\beta} \sigma (n - n_1) + G(\Phi(x_{n_1})).$$

So for all $n \geq n_1$

$$(\beta(1 - \theta) - \theta)[\Phi(x_n)]^{\beta(1-\theta)-\theta} \leq \frac{1}{c_0^{1+\beta} \sigma (n - n_1) + G(\Phi(x_{n_1}))}$$

or

$$[\Phi(x_n) - \Phi(x^\infty)] \leq \left( \frac{1}{\beta(1-\theta) - \theta c_0^{1+\beta} \sigma (n - n_1) + G(\Phi(x_{n_1}))} \right)^{\frac{1}{\beta(1-\theta)-\theta}}$$

(10) follows again using (20).
4 Application to an implicit scheme

In this section we apply our method to the following example, which to our best knowledge, has not been considered yet in our framework of asymptotic behaviors.

We consider a sequence $((u_n, v_n))_{n \in \mathbb{N}}$ in $\mathbb{R}^d \times \mathbb{R}^d$ satisfying

$$
\begin{cases}
\frac{u_{n+1} - u_n}{\Delta t} = v_{n+1} \\
\frac{v_{n+1} - v_n}{\Delta t} = -\|v_{n+1}\|^\alpha v_{n+1} - \nabla F(u_{n+1})
\end{cases}
$$

(23)

where $\alpha > 0$ and $F : \mathbb{R}^d \rightarrow \mathbb{R}$ is a $C^1$ function such that

$$
\exists c_F > 0, \forall u, v \in \mathbb{R}^d, <\nabla F(u) - \nabla F(v), u - v > \geq -c_F\|u - v\|^{\alpha + 2},
$$

(24)

$$
\exists L_F > 0, \forall u, v \in \mathbb{R}^d, \|\nabla F(u) - \nabla F(v)\| \leq L_F\|u - v\|.
$$

(25)

Let us remark that this case is more general than the case when $\alpha = 0$ already treated in [9], we think that our example thus generalizes the examples therein, though we require somewhat strong assumptions in order to have an ascertained situation.

Remark 4.1. Let us remark that the assumption that, for $C^2$ functions, (25) is equivalent to the fact that $\nabla^2 F$ is bounded, while condition (24) implies that $F$ is convex. Since, the condition (24) is only used in the proof of the next proposition and lemma 4.4, future works examining situations when (24) is not satisfied would probably be of nice interests.

The existence and uniqueness of a sequence satisfying (23) is not clear in general. The proposition below gives some sufficient conditions for which it is the case.

Proposition 4.2. Assume that $F$ is of class $C^2(\mathbb{R}^d)$, coercive and that (24) and (25) hold, then for any $(u_0, v_0) \in \mathbb{R}^{2d}$, provided $\Delta t$ is small enough, the sequence $(u_n, v_n)$ given by (23) is well defined, and we have

$$
\forall n \in \mathbb{N}, \quad \frac{1}{2}\|v_{n+1}\|^2 + F(u_{n+1}) \leq \frac{1}{2}\|v_n\|^2 + F(u_n).
$$

(26)

Proof. Let us now denote $E_0 = \frac{1}{2}\|v_0\|^2 + F(u_0)$. Due to the coercivity of $F$, we can choose some $R > 0$ such that if $F(u) \leq E_0$ then $u \in B(0, R)$. Let us also denote $R' = \sqrt{2E_0}$.

Let us consider some function $N_1 : \mathbb{R}^d \rightarrow \mathbb{R}^d$ which is $C^1$, bounded and globally lipschitz on $\mathbb{R}^d$ and such that $N_1(v) := \|v\|^\alpha v$ on $B(0, 3R')$. Let us also consider a function $N_2 : \mathbb{R}^d \rightarrow \mathbb{R}^d$ which is $C^1$ bounded and globally lipschitz and such that $N_2 = -\nabla F$ on $B(0, 3R)$. It is standard (see [6]) that provided $\Delta t$ is small enough, there exists a unique sequence $(u_n, v_n)$ such that

$$
\begin{cases}
\frac{u_{n+1} - u_n}{\Delta t} = v_{n+1} \\
\frac{v_{n+1} - v_n}{\Delta t} = -N_1(v_{n+1}) + N_2(u_{n+1}).
\end{cases}
$$

(27)
Let us remark that we have
\[ \|u_1\| \leq \|u_0\| + \Delta t\|v_1\| \]
\[ \|v_1\| \leq \|v_0\| + M\Delta t \]
where \( M = \|N_1\|_\infty + \|N_2\|_\infty \).

Thus we get
\[ \|u_1\| \leq \|u_0\| + \Delta t(\|v_0\| + M\Delta t) \]
\[ \|v_1\| \leq \|v_0\| + M\Delta t. \]

Thus for \( \Delta t \) small enough depending only on \( R \) and \( R' \) we have
\[ (u_1, v_1) \in B(0, 2R) \times B(0, 2R') \]
and thus \((u_1, v_1)\) satisfies
\[
\begin{cases}
\frac{u_1 - u_0}{\Delta t} = v_1 \\
\frac{v_1 - v_0}{\Delta t} = -\|v_1\|^\alpha v_1 - \nabla F(u_1)
\end{cases}
\]
(28)

Now if we apply the proof of Proposition 4.5 below with \( n = 0 \) we get that if \( \Delta t \) is small enough we have (26) with \( n = 0 \) (for \( n = 0 \) the proof of Proposition 4.5 only requires that assumptions (24) and (25) are satisfied and the fact that \((u_1, v_1)\) are solutions of (28)). We thus get \( F(u_1) \leq E_0 \) and \( \|v_1\| \leq R' \), we can thus proceed by induction and this gives the existence and uniqueness of a sequence satisfying (23). \( \Box \)

In the sequel all the results depend only on the existence and uniqueness of a unique sequence satisfying (27), which we assume. The previous proposition gives a sufficient condition for which this is the case.

Let \( S = \{ a \in \mathbb{R}^d / \nabla F(a) = 0 \} \). We assume also that there exists \( \theta \in (0, \frac{1}{2}] \) such that
\[
\forall a \in S \ \exists \delta_a > 0 \ \exists \nu_a > 0 \ / \ \forall u \in \mathbb{R}^d : \ ||u - a|| < \delta_a \implies ||\nabla F(u)|| \geq \nu_a |F(u) - F(a)|^{1-\theta}. \quad (29)
\]

**Proposition 4.3.** ([15, 16, 7, 5]) Assumption (29) is verified if one of the following two cases holds:
- \( F \) is a polynomial, or
- \( F \) is analytic and \( S \) is compact.

The proof is given in the appendix.

**Lemma 4.4.** The hypothesis (24) on \( F \) implies that
\[
\forall u, v \in \mathbb{R}^d \quad F(v) \geq F(u) + \langle \nabla F(u), v - u \rangle - \frac{c_F}{2} \|u - v\|^\alpha + 2.
\]
The proof is given in the appendix.

The energy of the system is defined by

$$E(u, v) = \frac{1}{2} \|v\|^2 + F(u).$$

**Proposition 4.5.** Assume $F$ satisfies (24). Let $(u_n, v_n)$ be a sequence satisfying (23), then we have

$$E(u_{n+1}, v_{n+1}) - E(u_n, v_n) \leq -\Delta t \left[ 1 - \frac{c_F}{2} (\Delta t)^{\alpha+1} \right] \|v_{n+1}\|^\alpha + 2.$$

**Proof.** By taking the scalar product of the second relation of (23) with $\Delta tv_{n+1}$, it comes

$$< \frac{v_{n+1} - v_n}{\Delta t}, \Delta tv_{n+1} > = -\Delta t \|v_{n+1}\|^\alpha + 2 < \nabla F(u_{n+1}), \Delta tv_{n+1} >$$

or

$$\|v_{n+1}\|^2 - < v_n, v_{n+1} > = -\Delta t \|v_{n+1}\|^\alpha + 2 < \nabla F(u_{n+1}), u_{n+1} - u_n > . \quad (30)$$

By using the Cauchy-Schwarz inequality, there holds

$$- < v_n, v_{n+1} > \geq -\frac{1}{2} \|v_{n+1}\|^2 - \frac{1}{2} \|v_n\|^2. \quad (31)$$

Combining (30) and (31), if follows that

$$\frac{1}{2} \|v_{n+1}\|^2 - \frac{1}{2} \|v_n\|^2 \leq -\Delta t \|v_{n+1}\|^\alpha + 2 < \nabla F(u_{n+1}), u_{n+1} - u_n > ,$$

and then

$$E(u_{n+1}, v_{n+1}) - E(u_n, v_n) \leq -\Delta t \|v_{n+1}\|^\alpha + 2 + F(u_{n+1}) - F(u_n) - < \nabla F(u_{n+1}), u_{n+1} - u_n > .$$

By using lemma 4.4, we get

$$E(u_{n+1}, v_{n+1}) - E(u_n, v_n) \leq -\Delta t \|v_{n+1}\|^\alpha + 2 \frac{c_F}{2} \|u_{n+1} - u_n\|^\alpha + 2$$

$$= -\Delta t \left[ 1 - \frac{c_F}{2} (\Delta t)^{\alpha+1} \right] \|v_{n+1}\|^\alpha + 2,$$

from which the proof is completed. \hfill \Box

In order to study the asymptotics of the sequence $(u_n)$, we define the $\omega$—limit set

$$\omega((u_n)_{n \in \mathbb{N}}) = \{ a \in \mathbb{R}^d : \exists n_k \rightarrow \infty / u_{n_k} \rightarrow a \}.$$

**Corollary 4.6.** Let $F$ satisfying (24) and assume that $0 < \Delta t < \left( \frac{2}{c_F} \right)^{\frac{1}{\alpha+1}}$. Let $(u_n, v_n)$ be a sequence satisfying (23). If $(u_n)$ is bounded, then $\lim_{n \rightarrow \infty} E(u_n, v_n)$ exists, $v_n \rightarrow 0$ and $\omega((u_n)_{n \in \mathbb{N}})$ is a nonempty compact connected subset of $S$. 

10
Proof. According to proposition 4.5, \((E(u_n, v_n))\) is non increasing, thus converges in \(\mathbb{R} \cup \{-\infty\}\). From the boundedness of \((u_n)\), we deduce that \((E(u_n, v_n))\) converges to a real number. Using again proposition 4.5, \(\sum \|v_{n+1}\|^{\alpha+2}\) converges, so \((v_n)\) tends to 0. Now as \((u_n)\) is bounded, the set \(\omega((u_n)_{n \in \mathbb{N}})\) is compact in \(\mathbb{R}^d\). Besides, from the first relation of (23), one deduces that \((u_{n+1} - u_n)\) tends to 0. It is standard to prove that \(\omega((u_n)_{n \in \mathbb{N}})\) is a connected part of \(\mathbb{R}^d\). The second relation in (23) shows that \(\omega((u_n)_{n \in \mathbb{N}}) \subset S\). \(\square\)

Theorem 4.7. Let \(F : \mathbb{R}^d \rightarrow \mathbb{R} C^2\) satisfying (24), (25) and (29). Assume also that \(0 < \Delta t < \left(\frac{2}{c_P}\right)^{\frac{1}{\alpha+1}}\) and \(\alpha \in (0, \frac{\theta}{1-\theta})\). Let \((u_n, v_n)\) be a sequence satisfying (23) and we assume that \((u_n)\) is bounded. Then there exists \(a \in S\) such that

\[
\lim_{n \to +\infty} \|v_n\| + \|u_n - a\| = 0.
\]

In addition as \(n \to +\infty\) we have

\[
\|u_n - a\| = O\left(n^{\frac{-\theta(1-\theta)n}{1-2\theta+\alpha(1-\theta)}}\right)
\]

(32)

Remark 4.8. If \(F\) is coercive (i.e. \(\lim_{\|u\| \to \infty} F(u) = +\infty\)), then \((u_n)\) is bounded.

Remark 4.9. The case \(\theta = \frac{\alpha+1}{\alpha+2}\) never occurs since \(\theta \in (0, \frac{1}{2}]\) and \(\frac{\alpha+1}{\alpha+2} > \frac{1}{2}\).

Proof. By corollary 4.6, \(v_n \to 0\) and \(\omega((u_n)_{n \in \mathbb{N}})\) is nonempty. Let \(a \in \omega((u_n)_{n \in \mathbb{N}})\). Then there exists \(n_k \to \infty\) such that \(u_{n_k} \to a\). By continuity of \(E\), we have \(\lim_{n \to \infty} E(u_n, v_n) = F(a)\). Up to make the variable change \(u = a + w\) and if we set \(g(w) = F(a + u) - F(a)\) (hence \(\nabla g(w) = \nabla F(a)\)), we can assume that \(a = 0\) and then \(F(0) = 0, \nabla F(0) = 0\).

Now let \(\varepsilon\) be a positive real, and we define for all \(u, v \in \mathbb{R}^d\)

\[
\Phi_\varepsilon(u, v) = E(u, v) + \varepsilon\|\nabla F(u)\|^\alpha < \nabla F(u), v >.
\]

Let us define \(x_n = (u_n, v_n)\). According to the proposition 4.5, for all \(n \in \mathbb{N}\) :

\[
\begin{align*}
\Phi_\varepsilon(x_{n+1}) - \Phi_\varepsilon(x_n) & \leq -\Delta t \left[1 - \frac{c_P}{2} (\Delta t)^{\alpha+1}\right] \|v_{n+1}\|^{\alpha+2} + \varepsilon \|\nabla F(u_{n+1})\|^{\alpha} < \nabla F(u_{n+1}), v_{n+1} > \\
& \quad -\|\nabla F(u_n)\|^{\alpha} < \nabla F(u_n), v_n > \quad \text{for} \quad T_1 \\
& \quad \text{for} \quad T_2 \\
T_1 & = \|\nabla F(u_{n+1})\|^{\alpha} < \nabla F(u_{n+1}), v_n - \Delta t\|v_{n+1}\|^{\alpha} v_{n+1} - \Delta t\nabla F(u_{n+1}) > \\
& = -\Delta t\|\nabla F(u_{n+1})\|^{\alpha+2} - \Delta t\|\nabla F(u_{n+1})\|^{\alpha} v_{n+1} + \|\nabla F(u_{n+1})\|^{\alpha} < \nabla F(u_{n+1}), v_n > \\
& \quad + \|\nabla F(u_{n+1})\|^{\alpha} < \nabla F(u_{n+1}), v_n > \\
& \leq -\Delta t\|\nabla F(u_{n+1})\|^{\alpha+2} + \Delta t\|\nabla F(u_{n+1})\|^{\alpha+1} v_{n+1} + \|\nabla F(u_{n+1})\|^{\alpha} < \nabla F(u_{n+1}), v_n > \\
\end{align*}
\]

(33)
\[ T_2 = -\|\nabla F(u_n)\|^\alpha < \nabla F(u_n), v_n > \]
\[ = -\|\nabla F(u_n)\|^\alpha < \nabla F(u_n) - \nabla F(u_{n+1}) + \nabla F(u_{n+1}), v_n > \]
\[ = -\|\nabla F(u_n)\|^\alpha < \nabla F(u_n) - \nabla F(u_{n+1}), v_n > \|
abla F(u_{n+1})\|\alpha < \nabla F(u_{n+1}), v_n > \]
\[ \leq \|\nabla F(u_n)\|^\alpha \|\nabla F(u_n) - \nabla F(u_{n+1})\|\|v_n\| - \|\nabla F(u_{n+1})\|\alpha < \nabla F(u_{n+1}), v_n > \]
\[ \leq L_F \Delta t \|\nabla F(u_n)\|^\alpha \|v_{n+1}\|\|v_n\| - \|\nabla F(u_{n+1})\|\alpha < \nabla F(u_{n+1}), v_n > . \quad (34) \]

\[ L_F \Delta t \|\nabla F(u_n)\|^\alpha \|v_{n+1}\|\|v_n\| \]
\[ \leq L_F \Delta t \|\nabla F(u_n) - \nabla F(u_{n+1}) + \nabla F(u_{n+1})\|\|v_{n+1}\|\|v_n\| \]
\[ \leq L_F \Delta t \left( \|\nabla F(u_n)\|^\alpha + \|\nabla F(u_{n+1})\|\alpha \right) \|v_{n+1}\|\|v_n\| \quad \text{(by (25) and (23))} \]
\[ \leq (L_F \Delta t)^{\alpha+1} \|v_{n+1}\|^{\alpha+1} \|v_n\| + L_F \Delta t \|\nabla F(u_{n+1})\|\|v_{n+1}\|\|v_n\| \]
\[ \leq (L_F \Delta t)^{\alpha+1} \|v_{n+1}\|^{\alpha+1} \|v_n\| + \Delta t \|v_{n+1}\|^{\alpha+1} v_{n+1} + \Delta t \nabla F(u_{n+1})\| \quad \text{(by (23))} \]
\[ \leq (L_F \Delta t)^{\alpha+1} \|v_{n+1}\|^{\alpha+2} + L_F^{\alpha+1}(\Delta t)^{\alpha+2} \|v_{n+1}\|^{\alpha+2} + L_F^{\alpha+1}(\Delta t)^{\alpha+2} \|v_{n+1}\|^{\alpha+1} \|\nabla F(u_{n+1})\| \]
\[ + L_F \Delta t \|\nabla F(u_{n+1})\|\|v_{n+1}\|^2 + L_F(\Delta t)^2 \|\nabla F(u_{n+1})\|\|v_{n+1}\|^{\alpha+2} \quad (35) \]
\[ + L_F(\Delta t)^2 \|\nabla F(u_{n+1})\|^{\alpha+1} \|v_{n+1}\|. \]

Since \( v_n \to 0 \), then without loss of generality we assume that for all \( \forall n \in \mathbb{N}, \quad \|v_n\| \leq 1. \quad (36) \)

From (33) we get
\[ T_1 \leq -\Delta t \|\nabla F(u_{n+1})\|^{\alpha+2} + \Delta t \|\nabla F(u_{n+1})\|^{\alpha+1} \|v_{n+1}\| \]
\[ + \|\nabla F(u_{n+1})\|^\alpha < \nabla F(u_{n+1}), v_n > . \quad (37) \]

Also from (35) we get
\[ L_F \Delta t \|\nabla F(u_n)\|^\alpha \|v_{n+1}\|\|v_n\| \]
\[ \leq (L_F \Delta t)^{\alpha+1} \|v_{n+1}\|^{\alpha+2} + L_F^{\alpha+1}(\Delta t)^{\alpha+2} \|v_{n+1}\|^{\alpha+2} + L_F^{\alpha+1}(\Delta t)^{\alpha+2} \|v_{n+1}\|^{\alpha+1} \|\nabla F(u_{n+1})\| \]
\[ + L_F \Delta t \|\nabla F(u_{n+1})\|\|v_{n+1}\|^2 + L_F(\Delta t)^2 \|\nabla F(u_{n+1})\|\|v_{n+1}\|^{\alpha+2} \quad (38) \]
\[ + L_F(\Delta t)^2 \|\nabla F(u_{n+1})\|^{\alpha+1} \|v_{n+1}\|. \]

Using (38) in (34), we get
\[ T_2 \leq (L_F \Delta t)^{\alpha+1} (1 + \Delta t) \|v_{n+1}\|^{\alpha+2} + L_F^{\alpha+1}(\Delta t)^{\alpha+2} \|v_{n+1}\|^{\alpha+1} \|\nabla F(u_{n+1})\| \]
\[ + L_F \Delta t (1 + \Delta t) \|\nabla F(u_{n+1})\|\|v_{n+1}\|^2 + L_F(\Delta t)^2 \|\nabla F(u_{n+1})\|^{\alpha+1} \|v_{n+1}\| \]
\[ - \|\nabla F(u_{n+1})\|^{\alpha} < \nabla F(u_{n+1}), v_n > . \quad (39) \]

12
On the other hand

\[ \|\nabla F(u_{n+1})\|^a < \nabla F(u_n), v_n > - \|\nabla F(u_n)\|^a < \nabla F(u_{n+1}), v_n > \]

\[ = [(\|\nabla F(u_{n+1})\|^a - \|\nabla F(u_n)\|^a)] < \nabla F(u_{n+1}), v_n > \]

\[ \leq \|\nabla F(u_{n+1})\|^a - \|\nabla F(u_n)\|^a \|\nabla F(u_{n+1})\| \|v_n\| \]

\[ \leq \|\nabla F(u_{n+1}) - \nabla F(u_n)\|^a < \nabla F(u_{n+1}), v_n > \]

\[ \leq (L_F\Delta t)^a \|v_{n+1}\|^a < \nabla F(u_{n+1}), v_n \| \text{ (by (25) and (23))} \]

\[ \leq (L_F\Delta t)^a \|v_{n+1}\|^a < \nabla F(u_{n+1}), v_{n+1} + \Delta t\|v_{n+1}\|^a v_{n+1} + \Delta t\nabla F(u_{n+1}) \| \text{ (by (23))} \]

\[ \leq (L_F\Delta t)^a \|v_{n+1}\|^a + (L_F)^a (\Delta t)^a \|v_{n+1}\|^2 + (L_F)^a (\Delta t)^a \|v_{n+1}\|^a \|\nabla F(u_{n+1})\|^a \]

By using (37) (39) and (40) we obtain

\[ T_1 + T_2 \leq -\Delta t\|\nabla F(u_{n+1})\|^a + \Delta t\|\nabla F(u_{n+1})\|^a v_{n+1} \]

\[ + (L_F\Delta t)^a (1 + \Delta t)\|v_{n+1}\|^a + L_F(\Delta t)^a \|v_{n+1}\|^a \]

\[ + L_F\Delta t(1 + \Delta t)\|\nabla F(u_{n+1})\|^a + (L_F)^a (\Delta t)^a \|v_{n+1}\|^2 \]

\[ + (L_F)^a (\Delta t)^a \|v_{n+1}\|^a \|\nabla F(u_{n+1})\|^2 \]

\[ \leq -\Delta t\|\nabla F(u_{n+1})\|^a + \Delta t(1 + L_F\Delta t)\|\nabla F(u_{n+1})\|^a v_{n+1} \]

\[ + (L_F\Delta t)^a (1 + \Delta t)\|v_{n+1}\|^a \]

\[ + [L_F^a (\Delta t)^a + (L_F\Delta t)^a (1 + \Delta t)] \|v_{n+1}\|^a \|\nabla F(u_{n+1})\| \]

\[ + L_F\Delta t(1 + \Delta t)\|\nabla F(u_{n+1})\|^a \|v_{n+1}\|^2 + (L_F)^a (\Delta t)^a \|v_{n+1}\|^a \|\nabla F(u_{n+1})\|^2 \]

Using now Young’s inequality, we find some constants \(c_3, c_4, c_5, c_6 > 0\) such that

\[ \Delta t(1 + L_F\Delta t)\|\nabla F(u_{n+1})\|^a v_{n+1} \leq \frac{\Delta t}{5} \|\nabla F(u_{n+1})\|^a + c_3 \|v_{n+1}\|^a \]

\[ [L_F^a (\Delta t)^a + (L_F\Delta t)^a (1 + \Delta t)] \|v_{n+1}\|^a \|\nabla F(u_{n+1})\| \leq \frac{\Delta t}{5} \|\nabla F(u_{n+1})\|^a + c_4 \|v_{n+1}\|^a \]

\[ L_F\Delta t(1 + \Delta t)\|\nabla F(u_{n+1})\|^a \|v_{n+1}\|^2 \leq \frac{\Delta t}{5} \|\nabla F(u_{n+1})\|^a + c_5 \|v_{n+1}\|^a \]

\[ (L_F)^a (\Delta t)^a \|v_{n+1}\|^a \|\nabla F(u_{n+1})\|^2 \leq \frac{\Delta t}{5} \|\nabla F(u_{n+1})\|^a + c_6 \|v_{n+1}\|^a \].

Hence

\[ T_1 + T_2 \leq -\frac{\Delta t}{5} \|\nabla F(u_{n+1})\|^a + ((L_F\Delta t)^a (1 + \Delta t) + c_3 + c_4 + c_5 + c_6) \|v_{n+1}\|^a. \]
Indeed, a simple computation gives

\[
\Phi_{\epsilon}(x_{n+1}) - \Phi_{\epsilon}(x_n) \leq -\Delta t \left[ 1 - \frac{c_F}{2} (\Delta t)^{\alpha + 1} \right] \|v_{n+1}\|^{\alpha + 2} + \epsilon (T_1 + T_2)
\]

\[
\leq -\Delta t \left[ 1 - \frac{c_F}{2} (\Delta t)^{\alpha + 1} \right] \|v_{n+1}\|^{\alpha + 2} - \frac{\epsilon \Delta t}{5} \|\nabla F(u_{n+1})\|^{\alpha + 2}
\]

\[
+ \epsilon ((L_F \Delta t)^{\alpha + 1} (1 + \Delta t) + c_3 + c_4 + c_5 + c_6) \|v_{n+1}\|^{\alpha + 2}.
\]

By choosing \(\epsilon = \bar{\epsilon} > 0\) small enough, we get constants \(\gamma, \gamma' > 0\) such that

\[
\Phi_{\bar{\epsilon}}(x_n) - \Phi_{\bar{\epsilon}}(x_{n+1}) \geq \gamma' \left[ \|v_{n+1}\|^{\alpha + 2} + \|\nabla F(u_{n+1})\|^{\alpha + 2} \right]
\]

\[
\geq \gamma \left[ \|v_{n+1}\| + \|\nabla F(u_{n+1})\| \right]^{\alpha + 2}. \tag{42}
\]

Let us show that when \((u_n)\) is a bounded sequence, \((x_n)\) satisfies (7) with the function \(\Phi_{\bar{\epsilon}}\).

Indeed, a simple computation gives

\[
\nabla \Phi_{\bar{\epsilon}}(u, v) = \left( \nabla F(u) + \bar{\epsilon} \nabla^2 F(u) \cdot v + \bar{\epsilon} \alpha \nabla F(u)
\right)
\]

\[
\cdot \nabla F(u)
\]

\[
\leq \left[ \|v_{n+1}\| + \|\nabla F(u_{n+1})\| \right]^{\alpha + 2}. \tag{43}
\]

On the other hand

\[
\|x_{n+1} - x_n\| = \|(u_{n+1} - u_n, v_{n+1} - v_n)\|
\]

\[
= \|\Delta t v_{n+1} - \Delta t v_{n+1} - \Delta t \nabla F(u_{n+1})\|
\]

\[
\leq 2 \left( \frac{2}{c_F} \right)^{\frac{1}{\alpha + 2}} \left[ \|v_{n+1}\| + \|\nabla F(u_{n+1})\| \right]. \tag{44}
\]

By combining (42) – (43) and (44), we get that \((\Phi_{\bar{\epsilon}}(x_n))\) satisfies (7) with \(\beta = \alpha + 1\) and

\[
\sigma = \min \left( \frac{2 c_F}{4}, \frac{c_F}{2}, \frac{1}{2^{\alpha + 2} \gamma}, \frac{2\gamma}{\alpha + 2} \right).
\]

From the remark 2.3, let \(B \subset \mathbb{R}^d \times \mathbb{R}^d\) be a ball containing \((u_n, v_n)\). For all \((u, v) \in B\)

\[
\|\nabla \Phi_{\bar{\epsilon}}(u, v)\|
\]

\[
= \|\nabla F(u) + \bar{\epsilon} \nabla^2 F(u) \cdot v + \bar{\epsilon} \alpha \nabla F(u)\|^{\alpha - 2} < \nabla F(u), v > \nabla^2 F(u) \cdot \nabla F(u) + \|v + \bar{\epsilon} \nabla F(u)\|^{\alpha - 2}
\]

\[
\geq (1 - \epsilon C) \|v\| + \|\nabla F(u)\|. \tag{45}
\]

By possibly taking \(\bar{\epsilon} > 0\) smaller, there exists \(\rho > 0\) such that

\[
\forall (u, v) \in B \quad \|\nabla \Phi_{\bar{\epsilon}}(u, v)\| \geq \rho \|v\| + \|\nabla F(u)\|. \tag{45}
\]
If $(a, b)$ is not a critical point of $\Phi$, then $\Phi$ satisfies (8) with $\theta = \frac{1}{2}$ as best exponent, thanks to the continuity of $\Phi$.

Let $(a, b) \in B$ be a critical point of $\Phi$. Then $\nabla F(a) = 0$ and $b = 0$. From (29)

$$\exists \delta_a > 0 \exists \nu_a > 0, \forall u \in \mathbb{R}^d : \|u - a\| < \delta_a \implies \|\nabla F(u)\| \geq \nu_a |F(u) - F(a)|^{1-\theta}. \quad (46)$$

On the other hand, by using the Cauchy-Schwarz inequality, we get

$$[\Phi(u, v) - \Phi(a, 0)]^{1-\theta} = \left[ \frac{1}{2} \|v\|^2 + F(u) - F(a) + \varepsilon \|\nabla F(u)\|^\alpha < \nabla F(u), v \right]^{1-\theta} \leq \|v\|^{(1-\theta)} + |F(u) - F(a)|^{1-\theta} + \|\nabla F(u)\|(\alpha + 1)(1-\theta)\|v\|^{1-\theta}. \quad (47)$$

Thanks to Young’s inequality we obtain

$$\|\nabla F(u)\|(\alpha + 1)(1-\theta)\|v\|^{1-\theta} \leq \|\nabla F(u)\| + \|v\|^{\frac{1-\theta}{\beta-\alpha(1-\theta)}}.\]$$

Then (47) becomes

$$[\Phi(u, v) - \Phi(a, 0)]^{1-\theta} \leq \|v\|^{2(1-\theta)} + |F(u) - F(a)|^{1-\theta} + \|\nabla F(u)\| + \|v\|^{\frac{1-\theta}{\beta-\alpha(1-\theta)}}.$$

Since $2(1-\theta)$ and $\frac{1-\theta}{\beta-\alpha(1-\theta)}$ are bigger than 1, using also (46), we get for all $(u, v) \in B$ with $\|v\| \leq 1$ and $\|u - a\| < \delta_a$

$$[\Phi(u, v) - \Phi(a, 0)]^{1-\theta} \leq \|v\| + |F(u) - F(a)|^{1-\theta} + \|\nabla F(u)\| + \|v\| \leq \left( 2 + \frac{1}{\nu_a} \right) \|\nabla F(u)\| + \|v\| \leq \frac{1}{\rho} \left( 2 + \frac{1}{\nu_a} \right) \|\nabla \Phi(u, v)\| \quad \text{by (45)}.$$

Therefore $\Phi$ satisfies (8). Moreover since $\alpha < \frac{\theta}{\beta-\theta}$, we have

$$\beta(1-\theta) = (\alpha + 1)(1-\theta) < \left( \frac{\theta}{\beta-\theta} + 1 \right) (1-\theta) = \frac{\theta}{1-\theta} (1-\theta) = 1,$$

and (9) is satisfied. All the assumptions of theorem 2.1 are thus satisfied.

In order to get the speed of convergence given in the theorem 4.7, it suffices to remark that when $\beta = 1 + \alpha$ we have

$$\frac{1 - \beta(1-\theta)}{\beta(1-\theta) - \theta} = \frac{\theta - (1-\theta)\alpha}{1 - 2\theta + \alpha(1-\theta)}.$$
5 Numerical simulations.

5.1 The finite dimensional case

In this section we present some numerical results on the implicit scheme given by (23). The simulations were performed with C++ and python3. We dealt with more general situations of $C^2$ functions $F$ than convex and coercive ones as well as we also performed some numerical simulations with a semi-implicit scheme (see below).

In the situation of (23), obtaining $(u_{n+1}, v_{n+1})$ from $(u_n, v_n)$ has been done by means of a Newton method.

We have considered different $F$ and different value of $\alpha$, even with $\alpha > 1$. The $F$s that we consider do not necessarily satisfy the conditions imposed in order to get convergences, but in many situations we observe numerical results that are conform to the predicted behavior.

Here are some pictures of the results of the simulations. In each, we have fixed a maximum number of iterations and a stopping condition on to the value of $F$ on the sequences constructed with respect to the minimum value of $F$.

5.1.1 Example 1

We considered the following situation: See figures (1) and (2) and (3) and (4).

$$F : \mathbb{R}^2 \to \mathbb{R}\quad \quad (u, v) \mapsto F(u, v) = \begin{cases} \frac{1}{2}(u^2 + 2v^2 - 1)^2 & \text{if } u^2 + 2v^2 - 1 \geq 0 \\ 0 & \text{elsewhere.} \end{cases}$$

$$\alpha = 0.4, \Delta t = 0.01 \text{ or } 0.1, N = 1000 \text{ is the maximum number of iterations.}$$
Figure 1: Simulation for (48). Here $\alpha = 0.4$ and $\Delta t = 0.01$, the dotted curve is the apparently decreasing relative energy $E(u_n, v_n)/E(u_0, v_0)$. The solid curve is the boundary of the zero level of $F$ (which is in its interior). Convergence occurs to a critical point of $F$ which may be in the interior of the zero level set of $F$. 
Figure 2: $\alpha = 0.4$ and $\Delta t = 0.01$, the dotted curve is the value of the velocity $v_n$. The solid curve describes the coordinates of $u_n$. The dash-dotted curve corresponds to the sequence $(u_n, F(u_n, v_n))$. 
Figure 3: Simulation for (48). Here $\alpha = 0.4$ and $\Delta t = 0.1$, the dotted curve is the relative energy $E(u_n, v_n)/E(u_0, v_0)$. The solid curve is the boundary of the zero level of $F$ (which is in its interior). Convergence occurs to a critical point of $F$ which seems to be on the boundary of the zero level of $F$. 

![Simulation diagram](image)
Figure 4: Simulation for (48). Here $\alpha = 0.4$ and $\Delta t = 0.1$, the dotted curve is the value of the velocity $v_n$. The solid curve describes the coordinates of $u_n$. The dash-dotted curve corresponds to the sequence $(u_n, F(u_n, v_n))$.

5.1.2 Example 2

We also considered the following situation: See figures (5) and (6) and (7) and (8).

$F : \mathbb{R}^2 \to \mathbb{R}$

$$(u, v) \mapsto F(u, v) = \begin{cases} \frac{1}{2}((u - 1)^2 + (v - 1)^2 - 1)^2 & \text{if } (u - 1)^2 + (v - 1)^2 - 1 \geq 0 \\ 0 & \text{elsewhere.} \end{cases}$$ (49)

$\alpha = 0.4$

$\Delta t = 0.01$ or 0.1

$N = 1000$ is the maximum number of iterations.
Figure 5: Simulation for (49). Here $\alpha = 0.4$ and $\Delta t = 0.01$, the dotted curve is the relative energy $E(u_n, v_n)/E(u_0, v_0)$ it is apparently decreasing. The solid curve is the boundary of the zero level of $F$ (which is in its interior). Convergence occurs to a critical point of $F$ which may be in the interior the zero level of $F$. 
Figure 6: $\alpha = 0.4$ and $\Delta t = 0.01$, the dotted curve is the value of the velocity $v_n$. The solid curve describes the coordinates of $u_n$. The dash-dotted curve corresponds to the sequence $(u_n, F(u_n, v_n))$. 
Figure 7: Simulation for (49). Here $\alpha = 0.4$ and $\Delta t = 0.1$, the dotted curve is the relative energy $E(u_n, v_n)/E(u_0, v_0)$. The solid curve is the boundary of the zero level of $F$ (which is in its interior). Convergence occurs to a critical point of $F$ which seems to be on the boundary of the zero level of $F$.

Figure 8: Simulation for (49). Here $\alpha = 0.4$ and $\Delta t = 0.1$, the dotted curve is the value of the velocity $v_n$. The solid curve describes the coordinates of $u_n$. The dash-dotted curve corresponds to the sequence $(u_n, F(u_n, v_n))$. 
5.1.3 Example 3

We also dealt with the following situation where $F$ is $C^2$ and non-convex: See figure (9)

$F : \mathbb{R}^2 \rightarrow \mathbb{R}$

$$(u, v) \mapsto F(u, v) = \frac{1}{2}((u - 1)^2 + (v - 1)^2 - 1)^2$$

$\alpha = 0.4$

$h = 0.01$

$N = 1000$ is the maximum number of iterations.

We also simulated the following: See figure (10)

Figure 9: $\alpha = 0.4$. We again observe the numerical convergence, but have no proof yet.

$$F : \mathbb{R}^2 \rightarrow \mathbb{R}$$

$$(u, v) \mapsto F(u, v) = (u - 1)^2 + (v - 1)^2 - 1)^2$$

$\alpha = 0.4$

$h = 0.1$

$N = 1000$ is the maximum number of iterations.

Here again we observe the numerical convergence.
5.2 Semi-implicit scheme

Let us also mention that we performed some simulations for the semi-implicit case, that is

\[
\begin{align*}
\frac{u_{n+1} - u_n}{\Delta t} &= v_{n+1} \\
\frac{v_{n+1} - v_n}{\Delta t} &= -\|v_{n+1}\|^\alpha v_{n+1} - \nabla F(u_n)
\end{align*}
\]

(52)

Though we do not have proof of the convergence of sequences satisfying (52) with assumptions similar to the ones for the implicit scheme, we believe that convergence holds as the following examples show.

5.2.1 Example 1

One of these example is the following: See figure (11)

\[
F : \mathbb{R}^2 \to \mathbb{R} \\
(u, v) \mapsto F(u, v) = ((u - 1)^2 + (v - 1)^2 - 1)^2
\]

\[\alpha = 0.5\]

\[h = 0.01\]

\[N = 1000\] is the number of iterations.
5.2.2 Example 2

See figure (12)

\[ F : \mathbb{R}^2 \to \mathbb{R} \]

\[ (u, v) \mapsto F(u, v) = ((u - 1)^2 + (v - 1)^2 - 1)^2 \]

\[ \alpha = 1.5 \]

\[ h = 0.001 \]

\[ N = 10000 \] is the number of iterations.
5.2.3 Example 3

See figure (13)

\[ F : \mathbb{R}^2 \to \mathbb{R} \]

\[ (u, v) \mapsto F(u, v) = \frac{u^4}{4} + \frac{u^2}{4} - \frac{u^2v}{2} \]

\[ \alpha = 0.5 \]

\[ h = 0.001 \]

\[ N = 10000 \] is the number of iterations.

Figure 13: \( \alpha = 1.5 \)

5.3 Approximating the nonlinear nonlocal wave equation.

We consider here the nonlinear wave equation set on a regular bounded connected subset of \( \mathbb{R}^N \). Moreover the nonlinearity that we consider here is nonlocal.

\[
\begin{aligned}
\begin{cases}
\frac{\partial^2 u}{\partial t^2} + \| \frac{\partial u}{\partial t} \|^2 \frac{\partial u}{\partial t} - \Delta u + f'(u) = 0, & (t, x) \in (0, \infty) \times \Omega, \\
u(t, x) = 0, & t > 0, x \in \partial \Omega, \\
u(0, x) = u^0(x), & \frac{\partial u}{\partial t}(0, x) = u^1(x).
\end{cases}
\end{aligned}
\]

where \( f : \mathbb{R} \to \mathbb{R} \) a \( C^2 \).

The reason for which the nonlinearity involves a nonlocal term (\( i.e. \) a \( L^2 \)-norm) comes from the fact the discretization that we are going to consider leads to a similar term as in (23).

Let us recall that for the equation (56) some convergence results were obtained in [3].

We wish to approximate the equation (56) by means of an implicit difference scheme in time
and a finite-element method in space.

For this we classically rewrite (56) as a system

\[
\begin{cases}
\frac{\partial v}{\partial t} + \| v \|^2 v - \Delta u + f'(u) = 0, \quad (t, x) \in (0, \infty) \times \Omega, \\
\frac{\partial v}{\partial t} = u, \quad (t, x) \in (0, \infty) \times \Omega, \\
u(t, x) = 0, \quad t > 0, \quad x \in \partial \Omega, \\
u(0, x) = u_0(x), \quad \frac{\partial u}{\partial t}(0, x) = u_1(x).
\end{cases}
\]  

(57)

We will restrict ourselves to the situation when \( u_i \in H^1_0(\Omega) \) for \( i = 0, 1 \).

The semi-implicit finite difference scheme in time that we consider consists of, given some time step \( h \), a sequence \((u_n, v_n)\) of elements of \( H^1_0(\Omega)^2\) such that

\[
\begin{cases}
\frac{v_{n+1} - v_n}{h} + \| v_{n+1} \|^2 v_{n+1} - \Delta u_{n+1} + f'(u_{n+1}) = 0 \\
u_{n+1} - u_n = v_{n+1} \\
u_0 = u_0^0 \\
u_1 = u_1^1.
\end{cases}
\]  

(58)

We consider now \( V \) a finite dimensional subspace of \( H^1_0(\Omega) \) of dimension \( N \) and take a basis of \( V \), \((\phi_k)_{k=1,...,N}\), orthonormal in \( L^2(\Omega) \).

We will approximate the implicit difference scheme in time by considering the following finite-element approximation of (58) We will now consider \((U_n, V_n) \in V \times V\) such that

\[
\begin{cases}
\int_{\Omega} \frac{V_{n+1} - V_n}{h} \phi_i + \int_{\Omega} \| V_{n+1} \|^2 V_{n+1} \phi_i + \int_{\Omega} (\nabla U_{n+1} \nabla \phi_i + f'(U_{n+1})\phi_i) \, dx = 0 \\
\int_{\Omega} \frac{U_{n+1} - U_n}{h} \phi_i \, dx = \int_{\Omega} V_{n+1} \phi_i \, dx
\end{cases}
\]  

(59)

If we write \( V_n = \sum_{k=1}^{N} V_{n,k} \phi_k \) and \( U_n = \sum_{k=1}^{N} U_{n,k} \phi_k \) then (59) becomes

\[
\begin{cases}
\frac{V_{n+1,k} - V_{n,k}}{h} + \| V_{n+1} \|^2 V_{n,k} + (\nabla \mathcal{F}(V_{n+1}))_k = 0 \\
\frac{U_{n+1,k} - U_{n,k}}{h} = V_{n+1,k} \\
k = 1, ..., N
\end{cases}
\]  

(60)

where

\[
\mathcal{F} : V \rightarrow \mathbb{R} \quad v \mapsto \mathcal{F}(v) = \frac{1}{2} \int_{\Omega} (\| \nabla v \|^2 + f(v)) \, dx.
\]
It can be easily seen that if \( f \) satisfies the conditions (24) and (25) so does \( \mathcal{F} \).

In this form, we see that (60) stands as the system (23) and thus provided \( f \) satisfies the assumptions required for the theorem 4.7, the results of convergence apply. Let us thus remark that in order to guarantee that \( \mathcal{F} \) satisfies (29) it is sufficient to assume that \( f \) is real analytic. This assumption is also made for the related situation in [9].

We have simulated the wave equation in dimension 1 with different examples. Unfortunately some of the simulations performed (for some specific initial data which we will not present here) lacks to have the asymptotic behaviour that is expected by the theoretical result, on the contrary to what happens when there are no nonlocal terms. We were not able though to overcome, without artefacts, these oscillations on standard computers. In order to get some numerical asymptotic convergence, in many cases adding some regularization on the velocity seems to be sufficient. For example, if one denotes \((v_i^j)\) the computed velocity at each discrete point of \([0,1]\), at time \(ih\), one may consider an intermediate step and define new values \((v_i^{j+1/2})\) as means of the \((v_i^j)\), e.g. \(v_i^{j+1/2} = \alpha_1 v_{i-1}^j + \alpha_2 v_i^j + \alpha_3 v_{i+1}^j\) where \(\alpha_j, j = 1, 2, 3\) are nonnegative numbers such that \(\alpha_1 + \alpha_2 + \alpha_3 = 1\). The asymptotic behavior of the corresponding continuous equation has not, to our knowledge been studied. In that situation the continuous equation would be related to

\[
\frac{\partial^2 u}{\partial t^2} + \|\frac{\partial u}{\partial t}\|_2^2 M(\frac{\partial u}{\partial t}) - \Delta u + f'(u) = 0
\]

where \(M\) is defined by \(M(h)\) the solution of \(-\Delta M(h) = h\) with either 0 boundary condition on a cell or the whole domain of study.

We present some very rough numerical results without proceeding to the aforementioned regularization.

Though we performed different simulations with different initial data and velocity, with \(\alpha = 0.5\), typically \(u_0\) and \(u_1\) are of the form

\[x \mapsto \lambda x(x - 1)(x - 1/2)\]

or some regular approximations of

\[x \mapsto \lambda \min(x, 1 - x)\]

or

\[x \mapsto \lambda(x(1 - x) + \sin(\pi * x))\]

with different \(\lambda\)s for \(u_0\) and \(u_1\), we show here a few among them.

We have considered \(f(x) = x - \sin(x)\) though it does not satisfy our assumptions on \(f\).

Here are some results of simulations:

In the case of figures (14) up to (18), we also computed the \(L^2\) norm of the function determined by \(U_n\) which seems to be decreasing after some iterations in time. We take \(\Delta t\) of the order of \(1/M^2\) where \(M\) is the number of points of discretization in \([0, 1]\).
Figure 14: $\alpha = 0.5$, $T = 9/16$, $f(x) = x - \sin(x)$. 
Figure 15: $\alpha = 0.5$, $T = 9/8$, $f(x) = x - \sin(x)$. 
Figure 16: $\alpha = 0.5$, $T = 45/8$, $f(x) = \sin(x) - x$. Here we can see some oscillations appearing, though there seem to have convergence to 0.
Figure 17: $\alpha = 0.5$, $T = 9/16$, $f(x) = \sin(x) - x$. 

$\mu_0(x) = \min(x, 1-x)$, $v_0 = 4u_0$, nb iterations = 900, Delta t = 1/1600
Figure 18: $\alpha = 0.5$, $T = 45/8$, $f(x) = \sin(x) - x$.

6 Appendix

Proof of the lemma 4.4. We pose $h = v - u$. By using the Taylor formula, we get

$$F(v) = F(u + h) = F(u) + \int_0^1 <\nabla F(u + sh), h> \, ds.$$ 

Then we have

$$F(v) - F(u) - <\nabla F(u), v - u> = \int_0^1 <\nabla F(u + sh) - \nabla F(u), h> \, ds$$

$$\geq \int_0^1 -c_F s^{\alpha+1} \|h\|^{\alpha+2} \, ds \quad \text{by (24)}$$

$$\geq -\frac{c_F}{\alpha+2} \|u - v\|^{\alpha+2}.$$ 

\[\square\]
Proof of the proposition 4.3. The first part of the proposition is a result of D’Acunto and Kurdyka (see [7]). The proof of the second part can be found in [5], we give it for completeness.

Since $F$ is analytic, then by using the result of Lojasiewicz [15, 16], we have for all $a \in S$

$$\exists \theta_a \in (0, \frac{1}{2}] \exists \delta_a > 0/ \forall u \in B(a, \delta_a) \quad \|\nabla F(u)\| \geq |F(u) - F(a)|^{1-\theta_a}. \quad (61)$$

As $S \subset \bigcup_{x \in S} B(x, \delta_x)$ and $S$ is compact, then there $x_1, \ldots, x_p \in S$ such that

$$S \subset \bigcup_{j=1}^{p} B(x_j, \delta_{x_j}).$$

Let $a \in S$, then there exists $j \in \{1, \ldots, p\}$ such that $a \in B(x_j, \delta_{x_j})$. Using (61) we deduce that $F(a) = F(x_j)$. On the other hand, since $F$ is continuous, then there exists $\mu > 0$ such that

$$\forall u \in B(a, \mu) \quad |F(u) - F(a)| \leq 1. \quad (62)$$

Let $\sigma_a = \inf (\mu, \delta_{x_j} - ||a - x_j||)$. Then obviously we have $B(a, \sigma_a) \subset B(x_j, \delta_{x_j}) \cap B(a, \mu)$. Using once again (61), we have for all $u \in B(a, \sigma_a)$

$$|F(u) - F(a)| \leq |F(u) - F(x_j)| + |F(x_j) - F(a)| \leq \|\nabla F(u)\|^{1-\theta_a}$$

Let $\theta = \min_{j \in \{1, \ldots, p\}} \theta_{x_j}$. By (62) we conclude that for all $a \in B(a, \sigma_a)$

$$|F(u) - F(a)|^{1-\theta} \leq |F(u) - F(a)|^{1-\theta_{x_j}} \leq \|\nabla F(u)\|.$$
