ABSTRACT

**Background and Aim:** Integrons play an essential role in disseminating drug resistance genes among bacteria. The aim of this study was to determine the prevalence of integrons, and Extended-Spectrum β-Lactamase (ESBL) genes in Escherichia coli (E. coli) isolates collected from patients with urinary tract infection (UTI) referred to teaching hospitals in Ardabil, Iran.

**Materials and Methods:** In this descriptive, cross-sectional study (2017-2018), 163 isolates of E. coli were collected from patients with UTI. The drug susceptibility pattern of these isolates to 12 common antibiotics was investigated using the disk diffusion method based on CLSI guidelines. The prevalence of class 1, 2, 3 integrons and ESBL genes was verified by the PCR method. Finally, the genetic variation of isolates was analyzed using the ERIC-PCR method.

**Results:** Of 163 isolates, 138 (84.7%) isolates were multidrug resistance (MDR) strains. The lowest and highest antibiotic resistance was reported to nitrofurantoin and ampicillin, with a resistance rate of 1.2% and 89.6%, respectively. The incidence of class 1 and 2 integrons was obtained in 39.9% and 14.1% of the isolates, respectively. Class 3 integron was not found in any of the isolates. Based on the ERIC-PCR fingerprinting method, 4 ERIC types were detected.

**Conclusion:** Our study showed that E. coli isolates taken from patients mainly were MDR strain and resistant to many of the common antibiotics used to treat urinary tract infections. Using the correct dose of medication and multidrug therapy would be effective in reducing the incidence of antibiotic resistance.

**Keywords:** Escherichia coli, Integron, Multi-drug resistance, UTI

1. Introduction

Escherichia coli is a member of the Enterobacteriaceae family. The intestinal tract of humans and warm-blooded animals is its natural habitat. Also, its presence in water and food indicates contamination with the feces (1). Even though E. coli is one of the most prevalent commensals, it has five pathotypes that are associated with intestinal and extraintestinal disease, including enteropathogenic E. coli (EPEC), enterohemorrhagic E. coli (EHEC), enterotoxigenic E. coli (ETEC), enteroinvasive E. coli (EIEC), entero-aggregative E. coli (EAEC), diffusely-adherent E. coli (DAEC), adherent-invasive E. coli (AIEC) and uropathogenic E. coli (UPEC) (1). These pathotypes differ in the type of disease and related virulence factors such...
as adhesions, toxins, polysaccharide capsules, invasins, extragenetic material, and pathogenicity-associated islands (PAIs). UPEC is typically responsible for over 90% of urinary tract infections (UTI). UTI is defined as inflammation and disorder of the urinary tract due to the invasion of pathogens. Clinical features of the disease range from urethritis and cystitis to severe complications like kidney infection, pyelonephritis, and even sepsis. According to previous studies, UTI is the most prevalent infectious disease worldwide. The prevalence of this disease in women is higher than in other people. It is estimated that approximately 40% to 60% of women encounter UTI at least once in their lifetime (2). Integrons are mobile genetic elements that can be found in plasmids, transposons, and chromosomes. They were primarily discovered in antibiotic resistance research. They had an essential role in acquiring, expressing, and disseminating resistant genes among pathogens, especially gram-negative bacteria, through horizontal gene transfer (HGT) movement. The structure of integrons principally consists of a gene expressing recombinases or integrase enzyme (intI gene), which is mediated in gene cassettes insertion, recombination site (attI), which is identified by the integrase, and a promoter (Pc) that facilitates transcription of gene cassettes. Thus far, four classes of integrons based on intI gene similarity and about 200 gene cassettes conferring resistance to aminoglycoside, β-lactams, chloramphenicol, quinolones, and trimethoprim have been detected. Incorporating more than one cassette into the integron is associated with resistance to several antibiotics and multiple drug resistance (MDR) strains. Previous studies confirmed a strong relationship between the presence of integrons and multiple drug resistance, especially in Enterobacteriaceae family members, which are also known as very opportunistic agents (3-5).

Extended-spectrum β-lactamas (ESBLs) are a group of β-lactamase enzymes that inactivate powerful antibiotics such as third-generation of cephalosporins. However, these bacteria are susceptible to cephemycins and carbapenems, as well as to the beta-lactamase-inhibitor compound. Although ESBL-producing bacteria are inhibited by cefamycins, AmpC type β-lactamase-producing bacteria can inactivate these agents. The genes expressing AmpC type β-lactamas can be determined on a chromosome or plasmid. In gram-negative bacteria, it is usually chromosomal and inducible. Despite ESBLs, AmpC type β-lactamas can also inactivate the beta-lactam/beta-lactam inhibitor combination. Plasmid-mediated AmpC lactamas are a severe threat in hospitals because these plasmids are easily transmitted through horizontal gene transfer way among species and mediated in nosocomial outbreaks.

Therefore, it is essential to identify molecular mechanisms by which bacteria can spread resistance genes among themselves and identify indigenous strain antibiotic resistance patterns. These data will help increase our awareness of the antibiotic resistance mechanisms and provide the best empirical therapy. In this regard, this work aimed to study the antibiotic susceptibility pattern of UPEC, prevalence of the classes 1, 2, 3 integrons, and prevalence of ESBLs and AmpC producing strains.

2. Materials and Methods

In this descriptive, cross-sectional study, a total of 163 E. coli isolates were recovered from urine specimens of patients admitted to Bu Ali and Imam Khomeini teaching Hospitals of Ardabil University of medical science in Iran (2017-2018). After obtaining written informed consent (ethical code: IR.ARUMS.REC. 1396.69), each patient’s demographic data, including age, sex, and underlying disease, were recorded. Biochemical tests, such as gram staining, oxidase, and catalase tests, indole production, methyl red, Voges-Proskauer (VP), Simmons citrate, hydrogen sulfide, and urea hydrolysis tests were employed for primary identification and phenotypic detection of E. coli isolates (6). The polymerase chain reaction (PCR) method was used for confirming the results acquired from the phenotypic tests by targeting 16srRNA specific gene as described previously (7). All isolates were stored at ~80°C in a freezing solution containing trypticase soy broth (Padtan Teb Co., Iran) and 20% glycerol (6).

Antimicrobial Susceptibility Testing

Kirby-Bauer disk diffusion method was employed to determine the antimicrobial susceptibility profile of isolates to 12 antibiotics based on the Clinical and Laboratory Standards Institute (CLSI) guidelines (8). The antibiotic discs were Ampicillin 10 μg, Cefazolin 30μg, Cefotaxime 30 μg, Cefazidime 30 μg, Cefepime 30 μg, Ceftriaxone 30 μg, Imipenem 10μg, Gentamicin 10μg, Amikacin 30μg, Nitrofurantoin 300 μg, Ciprofloxacin 5 μg and Trimethoprim-sulfamethoxazole 1.25/23.75 μg (9). In this study, E. coli ATCC 25922 strain was used as a control for drug susceptibility testing. Isolates were resistant to at least one antibiotic in three or more antibiotic classes and were considered as MDR strain.

DNA Extraction

DNA was extracted from colonies of E. coli isolates using the boiling method (10). In brief, the colonies were picked up from 18 h fresh culture nutrient agar plates and dissolved in 200 μL of DNA extraction buffer (Tris-HCl100 mM, pH=7.6, Tween20 0.05%, proteinase K, 200 μg/mL), incubated at 55°C for 3 h followed by 100°C for 10 min. After centrifugation at 5000 × rpm
for 10 min, the supernatant was used as a template for PCR.

**Detection of Class 1, 2 and 3 Integrons by Polymerase Chain Reaction (PCR)**

For detection of integrons in MDR *E. coli* isolates, 3 specific sets of primers were used as described in the study by Kargar et al. (11) (Table 1). All primers were provided by Cinnagene Co. (Tehran, Iran). The PCR reaction was prepared in a total volume of 25 μL containing 1x PCR buffer, 10 mM dNTP mix, 1.5 mmol MgCl₂, 0.2 mM of each dNTP, 1U of Taq DNA polymerase, 5-10 pmol of each primer, 0.5-1 μg of template DNA. The temperature profile for each gene is presented in Table 1. Finally, the PCR products were sequenced on one strand by Pishgam Biotech co. (Tehran, Iran). Obtain results were analyzed by DNAMAN and BLAST soft wares and submitted in Genbank (accession numbers: MK994976.1, MK994-977.1). A PCR reaction without DNA or primers was used as a negative control.

**Phenotypic Evaluation of Broad-Spectrum β-lactamase Production**

Determination of ESBL-producing strains was performed based on CLSI protocols using Double Disc Diffusion Test (DDDT) (12). The bacterial suspension (concentration of suspension adjusted to McFarland standard 0.5) cultured on Müller Hinton medium. Cefotaxime (30 μg) and cefotaxime (30 μg) / clavulanic acid (10 μg) disk (padtanteb, Iran) were placed on the medium at a distance of 2 cm from each other. After 24 hours of incubation at 37°C, the growth inhibition zone was examined. In strains with a growth inhibition zone of 5 mm or more around the cefotaxime / clavulanic acid disk compared to the zone around the cefotaxime disk, it was considered the ESBL-producing strain. After identifying the strains producing ESBLs enzymes, the prevalence of *CTX-M*, *SHV*, *TEM* genes was determined using Table 1 universal primers. Standard strain *E. coli* 25922 ATCC was used as the negative control of the test.

**AmpC Screening using the Disk Diffusion Method**

AmpC beta-lactamase-producing strains were identified using a cefoxitin screening test. In this test, a cefoxitin disc (cefoxitin30g) was used to screen AmpC beta-lactamase-producing strains on the strains that were not identified as producing ESBL enzymes. For this purpose, after culturing the bacterial suspension following the 0.5 McFarland standard, cefoxitin was placed on plates containing Müller-Hinton agar medium. The diameter of the zone of inhibition less than or equal to 18 mm indicated the presence of AmpC inducible beta-lactamase (13).

**Enterobacterial Repetitive Intergenic Consensus Polymerase Chain Reaction (ERIC-PCR)**

The ERIC-PCR was done in a total volume of 20 μL, containing 1x PCR buffer, 0.1% tween20, dNTPs 250 μM, 20 pmol of each primer, MgCl₂ 3.75 mM, Taq DNA polymerase 2units, DNA template 100 ng. Expected amplified products were separated by electrophoresis on 1.5% agarose gel along with 100 bp DNA marker (Cinnaclone, Iran) stained with a green viewer (Pars Tous, Iran) and visualized under UV illumination (VilbertLourmat Co., Japan) (14).

In order to cluster the isolates, based on band scoring, a matrix with 38 rows and 20 columns was prepared in which zero indicates the absence and one indicates the expression of the target gene in each isolate. The dissimilarity matrix and dendrogram plot were constructed using the 'binyery' method and ward D method, respectively. All statistical calculations were performed using R software version 3.5.1 (R Foundation for Statistical Computing, Vienna, Austria).

**Statistical Analysis**

Statistical analyses were done by SPSS version 22 (SPSS Inc., Chicago, IL., USA). The Chi-square and Mann–Whitney tests were employed to estimate the relationship between variables. The significance level was considered less than 0.05 (P<0.05).

**3. Results**

Of the 163 studied patients, 107 cases were female (66%), and 56 were male (34.4%). The average age of the patients was 31.96 ±30.6, with a mean of 20 years and a range of one year to 94 years. The ratio of women to men was 1:91 (P<0.001), which indicated a significant relationship between the age of men and women. Also, 84 cases (51.5%) were from Imam Khomeini Hospital, and 79 cases (48.5%) from Bou Ali Hospital, and 138 (84.7%) cases were multiple drug resistance strains (MDR). Biochemical tests along with amplification of the specific region of 16srrRNA were employed for the identification of *UPEC* strain. The amplification of 919 bp fragment of 16srrRNA of *UPEC* is presented in Figure 1.

Figure 1. Illustration of 16SrRNA PCR product on 1% Agarose gel; lane 1: Size Marker (Ladder100bp: CinnaClon, Iran); lane 2: Negative control; lane 4 to 9: Samples.

The highest and the lowest antibiotic resistance was against ampicillin (89.6%) and nitrofurantoin (1.2%), respectively. Resistance to other antibiotics was as follows: cefazolin 60.7%, cefepime 42.3%, cefotaxime 53.4%, ceftriaxone 49.1%, ceftazidime 49.7%, imipenem 36.2%, gentamicin 20.2%, amikacin 6.7%, ciprofloxacin 41.1% and sulfamethoxazole-trimethoprim 73.6% (Table 2).

Statistical analysis indicated a significant relationship between increasing age and increasing drug resistance (P<0.001). Also, a significant relationship was observed between sex and cotrimoxazole, cefotaxime, ciprofloxacin, and ceftriaxone antibiotics. The resistance rate of ceftriaxone (P=0.023), cefotaxime (P=0.049), and ciprofloxacin (P=0.033) were higher in men than in women. Still, about sulfamethoxazole-trimethoprim antibiotic, the resistance rate in women was higher than in men (P<0.001). A significant relationship was reported between the ciprofloxacin, gentamicin, nitrofurantoin, cefotaxime, ceftriaxone antibiotics with diabetes. The Resistance...
Integrons and Multidrug-Resistant Uropathogenic Escherichia coli

The results of the PCR assay showed that the prevalence of class I and 2 integrons was 39.9% (n=65) and 14.1% (n=23), respectively. No class 3 integron was verified in any samples (Figure 2). PCR products of \textit{IntI} and \textit{IntI2} were subjected to DNA sequencing by Applied Biosystems 3500 (Pishgam co., Tehran, Iran). The results of DNA sequencing were analyzed using DNAMAN v.4.0 (Lynnon Biosoft, USA) and BLAST soft wares and submitted in Genbank under accession number (MK994977.1, MK994976.1). \textit{IntI} had 100% identity with other sequences in Genbank, while \textit{IntI2} had 99% identity.

The results of the PCR assay showed that the prevalence of class I and 2 integrons was 39.9% (n=65) and 14.1% (n=23), respectively. No class 3 integron was verified in any samples (Figure 2). PCR products of \textit{IntI} and \textit{IntI2} were subjected to DNA sequencing by Applied Biosystems 3500 (Pishgam co., Tehran, Iran). The results of DNA sequencing were analyzed using DNAMAN v.4.0 (Lynnon Biosoft, USA) and BLAST soft wares and submitted in Genbank under accession number (MK994977.1, MK994976.1). \textit{IntI} had 100% identity with other sequences in Genbank, while \textit{IntI2} had 99% identity.

A significant association was observed between MDR strain and the presence of integrons (\(P=0.001\), OR = 6.34; 95% CI: 1.81, 22.17), such that the presence rate of integrons in MDR positive samples was 6.34 times more than the MDR negative samples.

Statistical analyses revealed a significant relevance between the \textit{Int2} variable and the type of hospital (\(P=0.011\)). Accordingly, at Imam Khomeini Hospital, 20.2% of the samples were carriers of type 2 integron (\textit{IntI2}), while at Bu Ali Hospital, this rate was 6.3%. Similar results were not seen about \textit{IntI1}. Also, a
statistically significant correlation between age–integron2 \((P=0.008)\) and sex–integron1 \((0.014)\) was observed. Out of 163 \(E.\ coli\) samples examined based on the phenotypic test, 76 (46.6\%) samples produced ESBLs. Among the ESBLs negative strains (87 samples), 10 isolates (11.49\%) were positive for AmpC production. The results of the prevalence of genes encoding beta-lactamase enzymes CTX-M, SHV, and TEM using PCR were 16.0, 1.8, and 14.1\%, respectively.

In this study, the ERIC-PCR fingerprinting method was used for differentiating and genotyping the limited number of isolates. Based on ERIC-PCR fingerprinting, 95\% confidence level, and 75\% similarity index, isolates were grouped into 4 clusters (ERIC types 1–4). As seen in Figure 3, most of the isolates in ET3 were taken from Bu Ali hospital, while most isolates obtained from Imam Khomeini Hospital are located in ET2.

**Figure 3.** Dendrogram created from enterobacterial repetitive intergenic consensus-polymerase chain reaction (ERIC-PCR) banding pattern of 38 UPEC isolated from patients admitted to teaching hospital in Ardabil province. Marked numbers were related to isolates obtained from Bu Ali hospital while rest of them were recovered from Imam Khomeini Hospital.
4. Discussion

UTI is one of the most common bacterial infections that affects approximately 150 million people worldwide each year (16). According to a study in Iran, the prevalence of this infection is about 13.3%, and UPEC is the most common causative agent (17).

Male infants, older men, and women of all ages are prone to UTI (18). Frequent recurrences of infection, pyelonephritis associated with sepsis, and severe renal destruction are urinary tract infection complications (19). Female gender, previous history of urinary tract infections, sexual activity, diabetes, obesity, genetic susceptibility, prolonged use of the urinary catheter, and old age are the most critical risk factors for urinary tract infection (20).

Trimethoprim/Sulfamethoxazole is a good choice for treating uncomplicated UTI, but resistance rates are high, and other antimicrobial agents such as first-generation cephalosporins and fluoroquinolones should be heeded (2). MDR is defined as the resistance to at least one antibiotic in 3 or more antimicrobial classes (21).

In this study, which was performed on 163 E. coli isolates from patients with urinary tract infections, the prevalence of MDR samples was 84.7%, indicating a high level of antibiotic resistance in these isolates. The prevalence of multidrug-resistant UPEC in other sites of Iran ranges from 10.5% to 79.2% related to Kashan and Hamedan provinces, respectively (22). Also, the global prevalence of MDR strains is increasing, especially in developing countries, due to misuse and overuse of antibiotics (23, 24).

In this study, the highest resistance was reported to ampicillin (89.6%), trimethoprim-sulfamethoxazole (73.6%), and cefazolin (60.7%), while the lowest resistance was to nitrofurantoin (1.2%). The rate of imipenem antibiotic resistance was 36.2%, which was higher than in previous studies (25-27). Our study showed that nitrofurantoin, amikacin, and gentamicin are the most effective antibiotics against MDR isolates.

In a similar study, Mihankhah et al. indicated that E. coli is the most prevalent agent of urinary tract infection in Iran and the highest rate of antibiotic resistance was against ampicillin (89.29%).

In a systematic review, Alizade concluded that the prevalence of antibiotic resistance in gram-negative bacteria, especially E. coli, varies from region to region in Iran and is dramatically rising (28).

Integrons, as a mobile genetic element, have a critical role in maintaining and spreading antimicrobial resistance among bacteria, particularly gram-negative ones. It is accepted that the presence of integrons in MDR strain is substantially higher than susceptible strains (29).

Previous studies in Iran have reported that pooled prevalence rates of class 1, 2 integron are 41.7% and 17.4%, respectively. In the case of E. coli, no cases of class 3 integron have been reported except for a study conducted by Kargar et al. (11) in which the presence of class 3 integron in E. coli was reported in Iran for the first time.

Extended-spectrum β-lactamases (ESBLs) are enzymes produced by different species in the Enterobacteriaceae family, among which E. coli is prominent. ESBLs can destroy potent beta-lactam antibiotics such as three and four generations of cephalosporin. Over 600 variants of ESBLs based on amino acid sequences diversity have been identified, of which TEM, SHV, OXA, and CTX-M are the most common (30).

In our study, the prevalence of ESBL producing strain was 46.62%, while in a similar study in Mashhad, the prevalence of ESBL-producing E. coli was 51.6% (31). A systematic review study in Iran estimated that 75% of E. coli producing ESBL has been isolated from UTI infection, and the prevalence of TEM, SHV, and CTX-M genes were 51%, 37% and 45% respectively (32). Based on the results of this study and our results, the prevalence of the TEM gene in Ardabil province is lower than in other provinces. Due to the increase of multidrug-resistant strains and resistance to routine drugs in treating urinary tract infections, proper use of antibiotics seems very necessary. The first-line drugs for the treatment of urinary tract infections are sulfamethoxazole-trimethoprim and nitrofurantoin. This study showed high-level resistance to sulfamethoxazole-trimethoprim. As a result, treatment with this antibiotic should be more limited. Thus, it is recommended to use other antibiotics such as nitrofurantoin, ciprofloxacin, levofloxacin, and amoxicillin/clavulanic acid to treat isolates resistant to this antibiotic. In the case of ESBLs strains, their identification should be reported because their treatment with penicillins, cephalosporins, and aztreonam will fail. In various studies, the proposed treatment regimen for these strains is using 4th generation cephalosporins such as cefepime and carbapenems (33).

Today, there are different ways for molecular typing of bacteria, among which ERIC-PCR is the fastest method for differentiating the isolates (34). Although PFGE is a standard gold method for molecular typing of bacteria, previous studies revealed that this method is more suitable, cost-effective, and convenient than other PCR-based methods (35, 36).
In our study, ERIC-PCR fingerprinting indicated that despite all isolates causing similar disease, at the genetic level, they are very polymorphic.

In ERIC-PCR analysis, the highest number of isolates was observed in cluster ET2 with 19 isolates. All isolates in this group were resistant to ampicillin and susceptible to nitrofurantoin; they were also isolated from individuals over 70 years old.

To summarize, the results of our study offer valuable information on the prevalence of antibiotic resistance among UPEC strains and provide an appropriate empiric selection of antibiotic therapy based on susceptibility patterns of indigenous strains and local studies.

5. Conclusion

Treatment of the MDR strains is challenging and costly, and rapid identification of these isolates and preventive strategies are vital. Also, identification of clinical risk factors, suitable drug doses, and therapy duration are essential for managing infections originated by these strains.

Acknowledgment

This study financially supported by Ardabil university of medical science and presented as a part of an M.Sc thesis (number: 046).

Conflict of Interest

There is no conflict of interest.
