Abstract

We derive a general sum rule relating the Higgs coupling to W and Z bosons to the total cross section of longitudinal gauge boson scattering in $I = 0, 1, 2$ isospin channels. The Higgs coupling larger than in the Standard Model implies enhancement of the $I = 2$ cross section. Such an enhancement could arise if the Higgs sector is extended by an isospin-2 scalar multiplet including a doubly charged, singly charged, and another neutral Higgs.

February 2011
Introduction. The LHC is on its way to discovering a Higgs boson and measuring or constraining its couplings to other Standard Model (SM) particles. The coupling to W and Z bosons are particularly important because they control the high-energy behavior of the scattering amplitude of longitudinally polarized electroweak gauge bosons. Theoretical constraints on that coupling were previously discussed in Ref. [1] in the framework of Strongly Interacting Light Higgs (SILH) [2], where an approximately elementary Higgs doublet arises as a pseudo-Goldstone boson in a strongly interacting sector. In this letter we revisit this question, without making reference to an elementary Higgs doublet field. By the Higgs boson we simply mean any light neutral scalar particle with custodial isospin 0 and a significant coupling to W and Z.

Parametrizing the Higgs coupling to W and Z as

\[ \mathcal{L}_{hVV} = \frac{h}{v} \left( 2m_W^2 W^+ W^- + m_Z^2 Z^+ Z^- \right) \]

we will see that there is a sum rule relating the coefficient \( a \) to a linear combination of the total cross sections in different isospin channels of longitudinal electroweak gauge boson scattering:

\[ 1 - a^2 = \frac{\alpha^2}{6\pi} \int_0^\infty \frac{ds}{s} \left( 2\sigma_{I=0}^{\text{tot}}(s) + 3\sigma_{I=1}^{\text{tot}}(s) - 5\sigma_{I=2}^{\text{tot}}(s) \right). \]

The equality holds for a light Higgs boson and in the limit of vanishing electroweak gauge couplings, \( g, g' \to 0 \). The SM predicts \( a = 1 \). Intriguingly, CMS recently reported an excess of Higgs-like events in the diphoton channel produced in association with 2 forward jets [3]. This may possibly be interpreted as an enhancement of the vector-boson-fusion Higgs production mode and therefore a hint for \( a > 1 \). From Eq. (2) it is clear that the Higgs coupling to W and Z exceeding the SM value implies that the cross section in the isospin-2 channel dominates over the remaining 2 channels, at least for a certain range of invariant mass \( s \). The simplest way to satisfy the sum rule with \( a > 1 \) is by introducing a resonance in the isospin-2 channel.

Derivation of the sum rule. Below we derive Eq. (2). We will use the equivalence theorem, where the scattering amplitudes of \( W^+_L, W^-_L, Z_L \) are approximated by scattering amplitudes of a triplet massless “pions” \( \pi^a \) parametrizing the coset space of the \( SU(2) \times SU(2)/SU(2)_V \) non-linear sigma model. The \( SU(2)_L \times U(1)_Y \) subgroup of \( SU(2) \times SU(2) \)

\[ \alpha \]

The fact that only one parameter \( a \) controls the Higgs coupling to both W and Z boson is the consequence of assuming custodial symmetry, which is strongly suggested by electroweak precision tests.
is weakly gauged by the electroweak vector fields. At low energies, where the only degrees of freedom are those of the SM (including the Higgs boson $h$), the most general Lagrangian with these symmetries can be parametrized as

$$\mathcal{L} = \frac{1}{2} (\partial_\mu h)^2 - V(h) + \frac{v^2}{4} \text{Tr} \left[ D_\mu U^\dagger D_\mu U \right] \left( 1 + 2a \frac{h}{v} + b \frac{h^2}{v^2} + \ldots \right), \quad U = e^{i \pi \sigma^a / v}. \quad (3)$$

where $D_\mu U = \partial_\mu U - i \left( g/2 \right) \sigma^a L^a_\mu U + i \left( g'/2 \right) B_\mu U \sigma^3$, but we will work in the limit $g, g' \to 0$.

Using isospin and crossing symmetry, the basic pion scattering amplitude must have the form

$$T_{ab \to cd} = \langle cd | S | ab \rangle = A_s \delta^{ab} \delta^{cd} + A_t \delta^{ac} \delta^{bd} + A_u \delta^{ad} \delta^{bc}, \quad (4)$$

where $A_s = A(s, t, u)$, $A_t = A(t, s, u)$, $A_u = A(u, t, s)$, and $s + t + u = 0$ for massless pions. At low energies, the amplitudes can be computed from the Lagrangian Eq. (3), which gives:

$$A(s, t, u) = \frac{s}{v^2} \left( 1 - a^2 \frac{s}{s - m_h^2} \right) \approx \left( 1 - a^2 \right) \frac{s}{v^2}. \quad (5)$$

In what follows we will use the amplitudes projected on definite isospin of the initial and final 2-pion state (see Appendix for a recap of isospin decomposition). In terms of the function $A(s, t, u)$ these projections are given by:

$$T_0(s, t) = 3A_s + A_t + A_u, \quad T_1(s, t) = A_t - A_u, \quad T_2(s, t) = A_t + A_u. \quad (6)$$

The idea of the proof is to consider a certain contour integral of a general linear combination of forward isospin amplitudes in the complex plane $s$

$$I_A = \frac{1}{2\pi i} \int_{C_0} ds \frac{A(s)}{s^2}, \quad A(s) = \sum_I w_I T_I(s) \equiv \sum_I w_I T_I(s, t = 0) \quad (7)$$

where $C_0$ is a small circle around $s = 0$. Here $T_I(s, t)$ are amplitudes in the full UV-complete theory. Since at low energies they can be approximated using Eq. (5), straightforward integration yields

$$I_A = (1 - a^2) (2w_0 + w_1 - w_2) / v^2. \quad (8)$$

On the other hand, deforming the circle to a big one and around the cuts on the real axis, as is customary in this kind of arguments [4], we get

$$I_A = \frac{1}{2\pi i} \left( \int_{C_\infty} \frac{ds}{s^2} A(s) + \int_0^\infty \frac{ds}{s^2} [A(s + i\epsilon) - A(s - i\epsilon)] - \int_0^\infty \frac{ds}{s^2} [A(-s - i\epsilon) - A(-s + i\epsilon)] \right) \quad (9)$$
where $C_{\infty}$ is the circle at infinity. We are thus relating IR physics parameter $a$ to the unknown (but potentially measurable) amplitudes at high energies, which far away from $s = 0$ can no longer be approximated using Eq. (5).

Next, we would like to express the contribution of the negative $s$ cut in terms of amplitudes evaluated at positive $s$. Crossing symmetry implies

$$T_{ab \rightarrow cd}(-s, t = 0) = T_{ad \rightarrow cb}(s, t = 0).$$

(10)

This means that $A_s$ goes to $A_u$ under $s \rightarrow -s$. Using Eq. (6) and its inverse, it is easy to get the corresponding relation for $T_I$’s:

$$T_0(-s) = \frac{1}{3}T_0(s) - T_1(s) + \frac{5}{3}T_2(s),$$

$$T_1(-s) = -\frac{1}{3}T_0(s) + \frac{1}{2}T_1(s) + \frac{5}{6}T_2(s),$$

$$T_2(-s) = \frac{1}{3}T_0(s) + \frac{1}{2}T_1(s) + \frac{1}{6}T_2(s).$$

(11)

It is now possible to combine the two cuts into a single positive $s$ integral. We get:

$$I_A = \frac{1}{2\pi i} \int_{C_{\infty}} \frac{ds}{s^2} A(s) + \frac{2w_0 + w_1 - w_2}{\pi} \int_0^\infty \frac{ds}{s^2} \left[ \frac{1}{3} \text{Im} T_0(s) + \frac{1}{2} \text{Im} T_1(s) - \frac{5}{6} \text{Im} T_2(s) \right],$$

(12)

Note that the weights $w_I$ factor out, and it’s exactly the same factor that occurs in Eq. (8).

The optical theorem relates the imaginary part of the forward amplitude to the total scattering cross section, $\text{Im} T_I(s) = s\sigma_t^{\text{tot}}(s)$ for massless pions. Then, assuming that the integral over the big circle vanishes, that is $A(s)$ grows slower than $s$ at infinity, and then comparing Eq. (8) and Eq. (12) we recover the sum rule Eq. (2).

A similar sum rule with $a = 0$ holds for pion-pion scattering in QCD, in which context it has been derived by Olsson [5]. It has also been given by Adler [6], in a reduced form as in Eq. (21) below. See also [7] for a recent discussion.

**Discussion.** Let us now comment on how general our result is. First of all, we are assuming that the electroweak symmetry breaking sector has a UV completion of a kind which makes it possible to speak of an analytic and unitary S-matrix even at energies much higher than the electroweak scale. This is a reasonably general assumption which should be valid for any field or string theory-type UV completion.

Second, in the process of our proof we had to assume that $A(s)$ grows strictly slower than $s$ at infinity, to make the integral over the big circle vanish. This assumption requires caution,
since the Froissart bound does allow total cross section \( O(\log^2 s) \), which would correspond to a forward scattering amplitude \( O(s \log^2 s) \). However, not all amplitudes are expected to grow maximally fast.

Suppose first that the UV completion is strongly coupled. Then we can hope to apply the Regge theory, which predicts the high energy behavior of the amplitude at \( s \gg t \) of the form

\[
T_{AB \rightarrow CD}(s, t) \sim Z\gamma_{AC}\gamma_{BD} s^{\alpha(0)+\alpha't} \quad \text{(modulo factors of log } s) \quad (13)
\]

where \( \alpha(0) \) and \( \alpha' \) are the intercept and the slope of the leading Regge trajectory which can be exchanged in the t-channel, \( \gamma_{AB} \) and \( \gamma_{CD} \) are the corresponding couplings, and \( Z \) is a trajectory-dependent complex number [8]. The amplitudes saturating the Froissart bound are those which can couple to the pomeron: the isospin 0 trajectory with quantum numbers of the vacuum and of intercept \( \alpha(0) = 1 \). On the other hand, processes with nonzero isospin exchange (like \( \pi^- p \rightarrow \pi^0 n \) in QCD) have cross sections falling off like a power of energy (the Pomeranchuk theorem).

Specializing to the pion scattering amplitude, the isospin 0 nature of the pomeron implies that \( \gamma_{ac} = C\delta_{ac} \) and

\[
T_{ab \rightarrow cd}(s, t = 0) = ZC^2 \delta_{ac}\delta_{bd} s + \ldots, \quad (14)
\]

while the terms which exchange isospin 1 and 2 in the t-channel must be power suppressed. From here it is obvious that the fixed isospin amplitudes have identical leading \( s \) behavior:

\[
T_I(s) \sim ZC^2 s, \quad I = 0, 1, 2. \quad (15)
\]

This causes problems in our proof, as both the contribution of the big circle is nonvanishing and the integrals over the negative and positive cuts are divergent before being combined (notice that generically \( \text{Im } Z \neq 0 \)). Fortunately, there is a simple way out. Let us use the freedom to choose the weights \( w_I \) in our proof so that \( w_0 + w_1 + w_2 = 0 \) (but \( 2w_0 + w_1 - w_2 \neq 0 \)). Then \( \mathcal{A}(s) \) grows slower than \( s \) and our argument goes through. Thus our theorem holds also for strongly coupled UV completions, as long as the Regge theory applies. Incidentally, Eq. (15) implies also the convergence of our sum rule (2), as the factors multiplying the isospin cross sections sum up to zero.

For the weakly coupled UV completions the story complicates somewhat. Such UV completions can contain massive vectors of isospin 1 whose t-channel exchange gives the
leading $s \gg M_V^2, \ s \gg t$ behavior of the form

$$T_{ab\to cd}(s, t) = g^2_V (\delta_{ab}\delta_{cd} - \delta_{ad}\delta_{bc}) \frac{s}{t - M_V^2} + \ldots, \quad (16)$$

which gives

$$\mathcal{A}(s) = (2w_0 + w_1 - w_2) \frac{g^2_V s}{M_V^2}, \quad s \gg M_V^2. \quad (17)$$

Notice that, unlike for the pomeron exchange, this asymptotic behavior is purely real and thus does not cause a divergence in the integrals over the cuts. Nevertheless, there is a nonvanishing contribution from the big circle, so that the RHS of our sum rule gets an extra contribution:

$$c_\infty = \frac{g^2_V v^2}{M_V^2}. \quad (18)$$

Since this contribution is positive, it does not modify our arguments given above that $a > 1$ needs an increase in the $I = 2$ cross section.

Let us now list a few physical scenarios for which our sum rule will be of interest. What are the possibilities for light scalars with $a \neq 1$? One example is to have a light dilaton \[9\]. In this case $a = v/f$, where $f$ is the scale of spontaneous conformal symmetry breaking of which the dilaton is the Goldstone boson. Perturbative intuition may suggest that $v < f$ (and hence $a < 1$) since all vevs contribute to $f$ but not necessarily to $v$. However, the fact that our some rule is not sign definite indicates that this reasoning may be too naive.

Spontaneous breaking of conformal symmetry producing a light dilaton does not look easy to come by without supersymmetry (although see \[10\]). A more generic possibility is to have a light Higgs as a pseudo-Goldstone boson of spontaneously broken global symmetry at a scale $f$ somewhat higher than $v$. Generic features of this scenario have been distilled in the SILH framework \[2\]. To first order in $\xi = v^2/f^2$, the coupling $a$ in SILH is related by

$$a = 1 - c_H \xi/2 \quad (19)$$

to the coefficient $c_H$ of a particular dimension 6 effective operator written in terms of a composite Higgs doublet field,

$$\mathcal{O}_H = \frac{c_H}{2f^2} \partial^\mu (H^\dagger H) \partial_\mu (H^\dagger H), \quad (20)$$

which renormalizes the Higgs boson wave function. Basic group theory implies \[1\] that for all ‘normal’ cosets $c_H > 0$, so that this effect always suppresses the coupling: $a < 1$. By
‘normal’ here we mean cosets $G/H$ based on a compact global symmetry group $G$. Only such cosets are allowed if the UV completion is described by a quantum field theory, since at high energies, where the full symmetry $G$ is expected to be restored, the symmetry currents of a non-compact global symmetry will have non sign-definite two point functions, which is inconsistent with unitarity. However, non-compact coset can be perfectly healthy as a low energy effective theory (as long as the unbroken group $H$ is compact). In fact, string theory low-energy effective actions (supergravities) often contain scalar fields living in non-compact cosets [11]. And if a pseudo-Goldstone Higgs boson lives in a non-compact coset, like $\text{SO}(4,1)/\text{SO}(4)$, then the wave function effect sign is reversed, and one obtains $a > 1$ [11, 12].

Our sum rule should apply both to compact and non-compact cosets. For $a < 1$ the composite Higgs boson ‘under-unitarizes’ the longitudinal WW scattering, as the scattering amplitude (5) continues to grow at $s \gg m_h^2$, although with a reduced coefficient. Our sum rule then suggests that unitarization is completed by heavier resonances of isospin 0 and 1. In fact, unitarization by isospin 1 heavy vectors is a possibility much discussed in the literature, although isospin 0 heavy scalars is also an option. On the other hand, for non-compact cosets $a > 1$ and one can say that the Higgs boson ‘over-unitarizes’. In this case the sum rules suggests isospin 2 resonances which could restore the unitarization balance.

We can rephrase our sum rule in terms of the total $\pi\pi$ scattering cross section for various charge combinations,

$$1-a^2 = \frac{v^2}{\pi} \int_0^\infty \frac{ds}{s} \left( \sigma_{00}^{\text{tot}} + \sigma_{0+}^{\text{tot}} - 2\sigma_{++}^{\text{tot}} \right) = \frac{v^2}{\pi} \int_0^\infty \frac{ds}{s} \left( 2\sigma_{+-}^{\text{tot}} - \sigma_{00}^{\text{tot}} - \sigma_{0+}^{\text{tot}} \right) = \frac{v^2}{\pi} \int_0^\infty \frac{ds}{s} \left( \sigma_{++}^{\text{tot}} - \sigma_{+-}^{\text{tot}} \right).$$

(21)

The last form is related to the sum rule

$$c_H = c_\infty + \frac{f^2}{\pi} \int_0^\infty \frac{ds}{s} \left( \sigma_{++}^{\text{tot}} - \sigma_{+-}^{\text{tot}} \right)$$

(22)

derived in Ref. [1] for the coefficient of the SILH effective operator (20), by very similar methods based on analyticity and crossing. In particular, Ref. [1] identified correctly that $c_\infty > 0$ may arise for perturbative UV-completions containing t-channel vector exchanges. Our sum rule is stronger as it uses the full power of the isospin and shows that the contact term $c_\infty$ is likely unnecessary for strongly coupled UV completions.

**UV completion of $a > 1$ via a Scalar Quintuplet.** Let us now examine the situation $a > 1$ more closely but without necessarily committing ourselves to the motivated scenarios
(dilaton, Higgs as a PGB) discussed above. Our sum rule demonstrates that $a > 1$ is possible only when there is an enhancement in the $I = 2$ channel of longitudinal electroweak gauge boson scattering, and the most natural way to produce such an enhancement is via an s-channel isospin 2 resonance. The sum rule fixes the coupling of such a resonance to the $W$ and $Z$ bosons. As we will now explicitly demonstrate, the value of this coupling can be understood by using the familiar concept of unitarization.

Consider an isospin-2 scalar quintuplet $Q = (Q^{++}, Q^+, Q^0, Q^-, Q^{--})$ with mass $m_Q$ coupled in the isospin invariant way (in the limit $g' \to 0$) to the electroweak gauge bosons:

$$\mathcal{L}_Q = \frac{g_Q}{v} \left\{ \sqrt{\frac{2}{3}} Q^0 \left( m_W^2 W^+ W^- - m_Z^2 Z^2_{\mu\mu} \right) + \left( Q^{++} m_W^2 W^+ W^- + \sqrt{2} Q^+ m_W m_Z W^- Z_{\mu} + \text{h.c.} \right) \right\}. \quad (23)$$

In the presence of the quintuplet the basic pion amplitude takes the form [13]

$$A(s, t, u) = \frac{s}{v^2} \left( 1 - a^2 \frac{s}{s - m_h^2} \right) + \frac{g_Q^2}{v^2} \left( \frac{s^2}{3(s - m_h^2)} - \frac{t^2}{2(t - m_Q^2)} - \frac{u^2}{2(u - m_Q^2)} \right). \quad (24)$$

In the considered case $a > 1$, at the energies $s \gg m_h^2$ the scattering amplitude still grows with $s$ but with a negative coefficient ('over-unitarization'). However, if the resonance coupling is fixed at

$$g_Q^2 = \frac{6}{5} (a^2 - 1), \quad (25)$$

then $A(s, t, u)$ stops growing at $s \gg M_Q^2$ and the perturbative unitarity is restored. The cross section corresponding to this coupling is precisely the one predicted by the sum rule.

This raises a curious question: is it possible to embed the above effective theory into a complete renormalizable model valid up to arbitrary high scales and having $a > 1$? The answer is yes. The Higgs sector of the minimal model with this property is a $3 \times 3$ matrix of scalar fields $\Phi$ transforming as $(3, 3)$ under global $SU(2) \times SU(2)$. Under $SU(2)_V$, $\Phi$ decomposes as $1 + 3 + 5$, where $3$ will be the eaten Goldstones $\pi^a$, while $1$ and $5$ are the $h$ and $Q$ of the above example. As usual, the electroweak symmetry is the subgroup of the global symmetry, with $SU(2)_L$ identified with one $SU(2)$ factor, and $U(1)_Y$ realized as the $T^3$ generator of the other $SU(2)$. The electroweak symmetry is broken to $U(1)_{em}$ by the vev $\langle \Phi \rangle = \frac{v}{2\sqrt{2}} I_{3 \times 3}$, which also breaks the global symmetry to the diagonal isospin $SU(2)_V$. The

\footnote{For a general discussion of extended Higgs sectors with custodial symmetry, see [14].}
singlet $h$, quintuplet $Q$, and the triplet of Goldstones $\pi^a$ (eaten by $W$ and $Z$) are embedded into $\Phi$ as\footnote{ $\Phi$ is defined to be a real $3 \times 3$ matrix in the adjoint (real) basis. In the charge basis which we’re using here the reality condition translates to $\Phi^\dagger = (R R^T) \Phi (R R^T)$ where $R$ is defined in Eq. (A.1). This in turn corresponds to $\Phi$ being equal to its complex conjugate under reflection with respect to the central $\Phi_{22}$ element.}

$$
\Phi = \begin{pmatrix}
\frac{v}{\sqrt{2}} + \frac{1}{\sqrt{3}} h - \frac{1}{\sqrt{6}} Q^0 + \frac{i}{\sqrt{2}} \pi^0 & -\frac{1}{\sqrt{2}} (Q^+ + i \pi^+) & -Q^{++} \\
-\frac{1}{\sqrt{2}} (Q^- + i \pi^-) & \frac{v}{2 \sqrt{2}} + \frac{1}{\sqrt{3}} h + \sqrt{\frac{2}{3}} Q^0 & -\frac{1}{\sqrt{2}} (Q^+ - i \pi^+) \\
-Q^{-} & -\frac{1}{\sqrt{2}} (Q^- - i \pi^-) & \frac{v}{2 \sqrt{2}} + \frac{1}{\sqrt{3}} h - \frac{1}{\sqrt{6}} Q^0 - \frac{i}{\sqrt{2}} \pi^0
\end{pmatrix}.
$$

The Higgs sector Lagrangian is

$$
\mathcal{L}_{\text{Higgs}} = \frac{1}{2} \text{Tr} \left[ D_\mu \Phi^\dagger D_\mu \Phi \right] - V(\Phi), \quad V(\Phi) = \frac{1}{2} m^2 \text{Tr}[\Phi^\dagger \Phi] + \lambda_1 \text{Tr}[\Phi^\dagger \Phi \Phi^\dagger \Phi] + \lambda_2 \text{Tr}[\Phi^\dagger \Phi] \text{Tr}[\Phi^\dagger \Phi]
$$

where $D_\mu \Phi = \partial_\mu \Phi - ig L_\mu a^a \Phi + ig' B_\mu \Phi T^3$ and the generators $T^a$ are defined in Eq. (A.2).

The singlet and quintuplet masses that follow are given by

$$
m_h^2 = (\lambda_1 + 3 \lambda_2) v^2, \quad m_Q^2 = \lambda_1 v^2,
$$

and can be dialed independently. It is straightforward to demonstrate that Eq. (27) leads to the singlet and quintuplet interactions with electroweak gauge bosons of the form Eq. (1) and Eq. (23) with the couplings $a = \sqrt{8/3}$, $g_Q = \sqrt{2}$. Clearly, $a > 1$ and the relation Eq. (25) is fulfilled.

Note that while the minimal custodially invariant renormalizable model with $a > 1$ predicts $a = \sqrt{8/3}$, in more general renormalizable models this relation can be easily relaxed. The coupling of the isospin singlet to $W$ and $Z$ can be reduced if $h$ mixes with a gauge singlet $N$, for example via a term $N \text{Tr}[\Phi^\dagger \Phi]$ in the potential. In that case two isospin singlet mass eigenstates with $a < \sqrt{8/3}$ are present in the spectrum, however one may reside at the TeV scale and not be easily discoverable at the LHC. The same goes for the model where $\Phi$ is accompanied by the usual Higgs double $H$, in which case 2 isospin singlets, 1 triplet, and 1 quintuplet are present in the physical spectrum. This last case is known in the literature as the Georgi-Machacek model [15].

**Comments on Higgs Phenomenology.** The increased coupling to the electroweak gauge bosons may have several effects on the Higgs phenomenology at the LHC, where by
Higgs we mean the isospin singlet $h$ (see also [14]). First of all, the Higgs decay width into WW and ZZ is enhanced:

$$\frac{\Gamma(h \to WW)}{\Gamma_{SM}(h \to WW)} = \frac{\Gamma(h \to ZZ)}{\Gamma_{SM}(h \to ZZ)} = a^2. \tag{29}$$

By the same token, the vector-boson-fusion Higgs production mode is enhanced compared to the SM.

The Higgs decay width into photons can be modified by two separate effects. First, the contribution of the $W$ boson loop to the $h \to \gamma\gamma$ amplitude, which is the dominant one in the SM, gets enhanced by $a$. However, if the model is UV completed with a scalar quintuplet, the symmetries allow the latter to couple to the Higgs as

$$L_{hQQ} = -2g_{hQQ}m_Q^2 \frac{h}{v} \left(|Q^{++}|^2 + |Q^+|^2 + \frac{1}{2}(Q^0)^2\right). \tag{30}$$

In particular, in the minimal renormalizable model Eq. (27) one finds $g_{hQQ} = \sqrt{\frac{m_h^2 + 2m_Q^2}{3m_Q^2}}$. Thus, the charged members of the quintuplet can enter the $h \to \gamma\gamma$ loop amplitude. Assuming only these two factors affect the decay (in particular, assuming that $h$ couples to fermions as in the SM), for $m_h \sim 125$ GeV the width is modified approximately as

$$\frac{\Gamma(h \to \gamma\gamma)}{\Gamma_{SM}(h \to \gamma\gamma)} \approx \left(\frac{a - \frac{2}{9} - \frac{5}{24}g_{hQQ}}{7/9}\right)^2. \tag{31}$$

Since the result depends on $g_{hQQ}$, which is a free parameter not constrained by unitarity arguments, we cannot make a definite prediction about the $h \to \gamma\gamma$ width. One should also remember that the Higgs production rates in all channels strongly depend on the Higgs couplings to the SM fermions, which may also be modified in the present context.

**Summary.** We argued that an observation of enhanced coupling of the Higgs boson to the $W$ and $Z$ bosons implies the enhancement of the longitudinal gauge boson scattering cross section in the isospin-2 channel, such as via a quintuplet of narrow resonances (including doubly charged ones) coupled to WW, WZ, and ZZ.

A Appendix: Isospin amplitudes

Everywhere in this paper we assumed that the electroweak symmetry breaking sector respects an \( SU(2) \times SU(2) \) global symmetry, spontaneously broken to the global \( SU(2)_V \) referred to as custodial isospin. As is well known, custodial isospin ensures the phenomenologically successful relation \( m_W/m_Z \approx \cos \theta_W \), and is therefore expected to remain a good approximate symmetry in any realistic extension of the SM. The three “pions” \( \pi^a \) (the Goldstone bosons that become longitudinal components of W and Z) transform as the triplet representation of custodial isospin. By isospin and crossing symmetry, all pion 2-to-2 scattering amplitude can be expressed by one function of the kinematic variables \( A(s,t,u) \) in the form given in Eq. (4).

Before we give the isospin decomposition of the pion amplitude, we first summarize our conventions for \( SU(2) \) generators. The triplet representation in the real (adjoint) basis \( \pi^a \) can be defined using the structure constants: \( (T^b)_{ac} = i \epsilon^{abc} \). It is often more convenient to work in the charge eigenstate basis where \( T^3 \) is diagonal,

\[
\begin{pmatrix}
\pi^+ \\
\pi^0 \\
\pi^-
\end{pmatrix} = R \cdot \begin{pmatrix}
\pi^1 \\
\pi^2 \\
\pi^3
\end{pmatrix}, \quad R = \begin{pmatrix}
\frac{1}{\sqrt{2}} & -i \sqrt{\frac{1}{2}} & 0 \\
0 & 0 & 1 \\
\frac{1}{\sqrt{2}} & i \sqrt{\frac{1}{2}} & 0
\end{pmatrix}.
\]  
(A.1)

The generators transform as \( T^a \rightarrow RT^a R^\dagger \), hence in the charge basis\(^4\)

\[
T^1 = \frac{1}{\sqrt{2}} \begin{pmatrix}
0 & -1 & 0 \\
-1 & 0 & 1 \\
0 & 1 & 0
\end{pmatrix}, \quad T^2 = \frac{1}{\sqrt{2}} \begin{pmatrix}
0 & i & 0 \\
-i & 0 & -i \\
0 & i & 0
\end{pmatrix}, \quad T^3 = \begin{pmatrix}
1 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & -1
\end{pmatrix}.
\]  
(A.2)

\(^4\)Our generators \( T^{1,2} \) differ by a sign convention from those used in most quantum mechanics textbooks. The reason is that, to arrive at the standard form, one needs to define the charge basis such that \( \pi^+ = - (\pi^-)^\dagger \) or \( \pi^0 = - (\pi^0)^\dagger \), which is rather awkward in the field theory context. Consequently, our Clebsch-Gordan coefficient in Eq. (A.5) also differ by a sign convention from the standard ones.
Using Eq. (A.1), the pion amplitudes in the charge basis can be easily derived from Eq. (4),
\[ T_{\pi^0\pi^0 \rightarrow \pi^+\pi^-} = A_s, \quad T_{\pi^0\pi^0 \rightarrow \pi^0\pi^0} = A_s + A_t + A_u \]
\[ T_{\pi^0\pi^0 \rightarrow \pi^0\pi^0} = A_t, \quad T_{\pi^+\pi^- \rightarrow \pi^+\pi^-} = A_s + A_t, \]
\[ T_{\pi^0\pi^0 \rightarrow \pi^0\pi^\pm} = A_u, \quad T_{\pi^\pm\pi^\pm \rightarrow \pi^\pm\pi^\pm} = A_t + A_u \]
(A.3)

We will also need the amplitudes in the isospin basis, which diagonalize the S-matrix:
\[ \langle I, m | S | I', m' \rangle = T_I(s,t)\delta_{II'}\delta_{mm'} \]  

(A.4)

The Wigner-Eckart theorem says that these amplitudes depend only on $I$ and not on $m$. Isospin decomposition of the $3 \times 3$ product representation is given by
\[
\begin{pmatrix}
|2, 2\rangle \\
|2, 1\rangle \\
|2, 0\rangle \\
|2, -1\rangle \\
|2, -2\rangle \\
\end{pmatrix}
= \frac{1}{\sqrt{2}} \begin{pmatrix}
|\pi^+\pi^+\rangle \\
|\pi^+\pi^-\rangle + |\pi^-\pi^+\rangle - 2|\pi^0\pi^0\rangle \\
|\pi^-\pi^-\rangle \\
|\pi^-\pi^0\rangle + |\pi^0\pi^-\rangle \\
|\pi^0\pi^-\rangle \\
\end{pmatrix},
\begin{pmatrix}
|1, 1\rangle \\
|1, 0\rangle \\
|1, -1\rangle \\
\end{pmatrix}
= \frac{1}{\sqrt{2}} \begin{pmatrix}
|\pi^+\pi^0\rangle - |\pi^0\pi^+\rangle \\
|\pi^+\pi^-\rangle - |\pi^-\pi^+\rangle \\
|\pi^-\pi^0\rangle - |\pi^0\pi^-\rangle \\
\end{pmatrix},
\]
\[ |0, 0\rangle = \frac{1}{\sqrt{3}} \left( |\pi^+\pi^-\rangle + |\pi^-\pi^+\rangle + |\pi^0\pi^0\rangle \right). \] 

(A.5)

Eq. (A.5) together with Eq. (A.3) immediately lead to the isospin amplitudes given in Eq. (6).
