Non-Abelian String and Particle Braiding in Topological Order: 
Modular SL(3, Z) Representation and 3+1D Twisted Gauge Theory

String and particle braiding statistics are examined in a class of topological orders described by discrete gauge theories with a gauge group $G$ and a 4-cocycle $\omega_4$ of $G$’s cohomology group $H^4(G, \mathbb{R}/\mathbb{Z})$ in 3 dimensional space and 1 dimensional time (3+1D). We establish the topological spin and the spin-statistics relation for the closed strings, and their multi-string braiding statistics. The 3+1D twisted gauge theory can be characterized by a representation of a modular transformation group SL(3, Z). We express the SL(3, Z) generators $S^{xy}$ and $T^{xy}$ in terms of the gauge group $G$ and the 4-cocycle $\omega_4$. As we compactify one of the spatial directions $z$ into a compact circle with a gauge flux $b$ inserted, we can use the generators $S^{xy}$ and $T^{xy}$ of an SL(2, Z) subgroup to study the dimensional reduction of the 3D topological order $C^{3D}$ to a direct sum of degenerate states of 2D topological orders $C_b^{2D}$ in different flux $b$ sectors: $C^{3D} = \oplus_b C_b^{2D}$. The 2D topological orders $C_b^{2D}$ are described by 2D gauge theories of the group $G$ twisted by the 3-cocycles $\omega_3(b)$, dimensionally reduced from the 4-cocycle $\omega_4$. We show that the SL(2, Z) generators, $S^{xy}$ and $T^{xy}$, fully encode a particular type of three-string braiding statistics with a pattern that is the connected sum of two Hopf links. With certain 4-cocycle twists, we discover that, by threading a third string through a particular type of three-string braiding statistics with a pattern that is the connected sum of two Hopf links. With certain 4-cocycle twists, we discover that, by threading a third string through a particular type of three-string braiding statistics with a pattern that is the connected sum of two Hopf links.

I. INTRODUCTION

In the 1986 Dirac Memorial Lectures, Feynman explained the braiding statistics of fermions by demonstrating the plate trick and the belt trick. Feynman showed that the wavefunction of a quantum system obtains a mysterious $(-1)$ sign by exchanging two fermions, which is associated with the fact of requiring an extra $2\pi$ twist or rotation to go back to the original state. However, it is known that there is richer physics in deconfined topological phases of 2+1D and 3+1D spacetime. In 2+1D, there are “anyons” with exotic braiding statistics for point particles. In 3+1D, Feynman only had to consider bosonic or fermionic statistics for point particles, without worrying about anyonic statistics. Nonetheless, there are string-like excitations, whose braiding process in 3+1D can enrich the statistics of deconfined topological phases. In this work, we aim to systematically address the string and particle braiding statistics in deconfined gapped phases of 3+1D topological orders. Namely, we aim to know what statistical phase does the wavefunction of the whole system gain under the string and particle braiding process.

Since the discovery of 2+1D topological orders4–6 (see Ref.7 for an overview), we have now gained quite systematic ways to classify and characterize them, by using the induced representations of the mapping class group of $T^2$ torus (the modular group $SL(2, Z)$ and the gauge/Berry phase structure of ground states6,8–9) and the topology-dependent ground state degeneracy,6,10,11 using the unitary fusion categories,12–19 and using simple current algebra,20–23 pattern of zeros,24–29 and field theories.30–34 Our better understanding of topologically ordered states also holds the promises of applying their rich quantum phenomena, including fractional statistics3 and non-Abelian anyons, for topological quantum computation.35

However, our understanding of 3+1D topological orders is in its infancy and far from systematic. This motivates our work attempting to address:

Q1: “How to (at least partially) classify and characterize 3D topological orders?”

By classification, we mean to count the number of distinct phases of topological orders and to give them a proper label. By characterization, we mean to describe their properties in terms of physical observables. Here our approach to study d-dimensional topological orders is to simply generalize the above 2D approach, to use the ground state degeneracy (GSD) on $d$-torus $T^d = (S^1)^d$, and the associated representations of the mapping class group of $T^d$ (recently proposed in Ref.19 and 38),

$$\text{MCG}(T^d) = \text{SL}(d, Z).$$  

(Refer to Appendix A 4 and Reference cited therein for a brief review of the computation of 2D topological orders.) For 3D, the mapping class group $SL(3, Z)$ is generated by the modular transformation $\hat{S}^{xyz}$ and $\hat{T}^{xy}$:

$$\hat{S}^{xyz} = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad \hat{T}^{xy} = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{2}$$

What are examples of 3D topological orders? One class of them is described by a discrete gauge theory with a finite gauge group $G$. Another class is described by the twisted gauge theory,36 a gauge theory $G$ with a 4-cocycle twist $\omega_4 \in H^4(G, \mathbb{R}/\mathbb{Z})$ of $G$’s fourth cohomology group. But the twisted gauge theory characterization of 3D topological orders is not one-to-one: different pairs $(G, \omega_4)$ can describe the same 3D topological order. In this work, we will use $\hat{S}^{xyz}$ and $\hat{T}^{xy}$ of $SL(3, Z)$ to characterize the topological twisted discrete gauge theory with finite gauge group $G$, which has topology-dependent ground state degeneracy. The twisted gauge theories describe a large class of 3D gapped quantum liquids in condensed matter. Although we will study the $SL(3, Z)$ modular data of the ground state sectors of gapped phases, these data can capture the gapped excitations such as particles and strings. (This strategy is widely-used especially in 2D.) There are two main issues that we will focus on addressing. The first is the dimensional reduction from 3D to 2D of $SL(3, Z)$ modular transformation and cocycles to study 3D topological order. The second is the non-Abelian three-string braiding statistics from a twisted discrete gauge theory of an Abelian gauge group.

(*1) Dimensional Reduction from 3D to 2D: for $SL(3, Z)$ modular $S$, $T$ matrices and cocycles - For the first issue, our general philosophy is the following: 

“Since 3D topological orders are foreign and unfamiliar
to us, we will *dimensionally reduce 3D topological orders to several sectors of 2D topological orders in the Hilbert space of ground states* (not in the real space, see Fig.1). Then we will be able to borrow the more familiar 2D topological orders to understand 3Ds."

We will compute the matrices $S^{xy}$ and $T^{xy}$ that generate the SL(3, $\mathbb{Z}$) representation in the quasi-(particle or string)-excitations basis of 3+1D topological order. We find an explicit expression of $S^{xy}$ and $T^{xy}$, in terms of the gauge group $G$ and the 4-cocycle $\omega_4$, for both Abelian and non-Abelian gauge groups. (A calculation using a different novel approach, the universal wavefunction overlap for the normal untwisted gauge theory, is studied in Ref.39.) We note that SL(3, $\mathbb{Z}$) contains a subgroup SL(2, $\mathbb{Z}$), which is generated by $\hat{S}^{xy}$ and $\hat{T}^{xy}$, where

$$\hat{S}^{xy} = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \quad (3)$$

In the most generic cases of topological orders (potentially *without a gauge group description*), the matrices $S^{xy}$ and $T^{xy}$ can still be block diagonalized as the sum of several sectors in the quasi-excitations basis, each sector carrying an index of $b$,

$$S^{xy} = \oplus_b S_b^{xy}, \quad T^{xy} = \oplus_b T_b^{xy}, \quad (4)$$

The pair $(S_b^{xy}, T_b^{xy})$, generating an SL(2, $\mathbb{Z}$) representation, describes a 2D topological order $C_b^{2D}$. This leads to a dimension reduction of the 3D topological order $C^{3D}$:

$$C^{3D} = \oplus_b C_b^{2D}. \quad (5)$$

In the more specific case, when the topological order allows a gauge group description which we focus on here, we find that the $b$ stands for a gauge flux for group $G$ (Namely, $b$ is a group element for an Abelian $G$, while $b$ is a conjugacy class for a non-Abelian $G$).

The physical picture of the above dimensional reduction is the following (see Fig.1): If we compactify one of the 3D spatial directions (say the $z$ direction) into a small circle, the 3D topological order $C^{3D}$ can be viewed as a direct sum of 2D topological orders $C_b^{2D}$ with (accidental) degenerate ground states at the lowest energy.

FIG. 2. Mutual braiding statistics following the path $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$ along the time evolution (see Sec.III C 2): (a) From a 2D viewpoint of dimensional reduced $C_b^{2D}$, the 2π braiding of two particles is shown. (b) The compact $z$ direction extends two particles to two closed (red, blue) strings. (c) An equivalent 3D view, the $b$ flux (along the arrow - - - ) is regarded as caused by a third (black) string. We identify the coordinates $x, y$ and a compact $z$ to see that a full-braiding process is the *one (red) string going inside to the loop of another (blue) string, and then going back from the outside*. For Abelian topological orders, the mutual braiding process between two excitations (A and B) in Fig.2(a) yields a statistical Abelian phase $e^{i\theta(A,B)} \propto S^{xy}_{(A)(B)}$ proportional to the 2D’s $S^{xy}$ matrix. The dimensional-extended equivalent picture Fig.2(c) implies that the loop-braiding yields a phase $e^{i\theta(\lambda,\mu)}(b) \propto S^{xy}_{b(\lambda)(\mu)}(A)(B)$ of Eq.(34) (up to a choice of canonical basis), where $b$ is the flux of the black string. We clarify that in both (b) and (c) our strings may carry both flux and charge. If a string carries only a pure charge, then it is effectively a point particle in 3D. If a string carries a pure flux, then it is effectively a loop of a pure string in 3D. If a string carries both charge and flux (as a dyon in 2D), then it is a loop with string fluxes attached with some charged particles in 3D. Therefore our Fig.2(c)’s string-string braiding actually represents several braiding processes: the particle-particle, particle-loop and loop-loop braidings, all processes are threaded with a background (black) string.

In this work, we will focus on a generic finite Abelian gauge group $G = \prod_i Z_{N_i}$ (isomorphic to products of cyclic groups) with generic cocycle twists from the group cohomology. We examine the 3+1D twisted gauge theory twisted by 4-cocycle $\omega_4 \in H^4(G, \mathbb{R}/\mathbb{Z})$ of $G$’s third cohomology group, namely

$$C^{3D}_{G,\omega_4} = \oplus_b C_b^{2D}. \quad (6)$$

Surprisingly, even for an Abelian group $G$, we find such a *twisted Abelian gauge theory* can be dual to a twisted or
untwisted non-Abelian gauge theory. We study this fact for 3D as an extension of the 2D examples of Ref.42. By this equivalence, we are equipped with (both untwisted and twisted) non-Abelian gauge theory to study its non-Abelian braiding statistics.

(2) Non-Abelian three-string braiding statistics - We are familiar with the 2D braiding statistics: there is only particle-particle braiding, which yields bosonic, fermionic or anyonic statistics by braiding a particle around another particle.4 We find that the 3D topological order introduces both particle-like and string-like excitations. We aim to address the question:

Q2: “How to characterize the braiding statistics of strings and particles in 3+1D topological orders?”

The possible braiding statistics in 3D learned in the past literature are:
(i) particle-particle braiding can only be bosonic or fermionic due to no nontrivial braid group in 3D for point particles.
(ii) particle-string braiding, which is Aharonov-Bohm effect of $\mathbb{Z}_N$ gauge theory, where a particle as $\mathbb{Z}_N$ charge braiding around a string (or a vortex line) as $\mathbb{Z}_N$ flux, obtaining a $e^{i\pi \mathbb{Z}_N}$ phase of statistics.3,4
(iii) string-string braiding, where a closed string (a red loop), shown in Fig.2(c) excluding the background black string, wrapping around a blue loop. The related idea known as loop-loop braiding forming the loop braid group has been proposed mathematically.44 (See also some earlier studies in Ref.45 and 46.)

However, we will address that there are some extra new braiding statistics between three closed strings:
(iv) three-string braiding, shown in Fig.2(c), where a closed string (a red loop) wrapping around another closed string (a blue loop) but the two loops both are threaded by a third loop (the black string). This braiding configuration is discovered recently by Ref.40, also a related work in Ref.41 for a twisted Abelian gauge theory.

The new ingredient of our work on braiding statistics can be summarized as follows: We consider the string and particle braiding of general twisted gauge theories with the most generic finite Abelian gauge group $G = \prod_{a} \mathbb{Z}_{N_a}$, labeled by the data $(G,\omega)$. We provide a 3D to 2D dimensional reduction approach to realize the three-string braiding statistics of Fig.2. We firstly show that the SL(2, $\mathbb{Z}$) representations $(\mathbb{S}_{b_{xy}}^{xy}, \mathbb{T}_{b_{xy}}^{xy})$ fully encode this particular type of Abelian three-closed-string statistics shown in Fig.2. We further find that, for a twisted gauge theory with an Abelian ($\mathbb{Z}_N$)4 group, certain 4-cocycles (named as Type IV 4-cocycles) will make the twisted theory to be a non-Abelian theory. More precisely, while the two-string braiding statistics of unlink is Abelian, the three-string braiding statistics of Hopf links, obtained from threading the two strings with a third string, will become non-Abelian. We also demonstrate that $(\mathbb{S}_{b_{xy}}^{xy})$ encodes this three-string braiding statistics.

Our article is organized as follows. In Sec.II, we address a third question: Q3: “How to formulate or construct certain 3+1D topological orders on the lattice?” We outline a lattice formulation of twisted gauge theories in terms of 3D twisted quantum double models, which generalize the Kitaev’s 2D toric code and quantum double models. Our model is the lattice Hamiltonian formulation of Dijkgraaf-Witten theory,36 and we provide the spatial lattice as well as the spacetime lattice path integral pictures. In Sec.III, we answer Q4: “What are the generic expressions of SL(3, $\mathbb{Z}$) modular data?” We compute the modular SL(3, $\mathbb{Z}$) representations of $\mathbb{S}$, $\mathbb{T}$ matrices, using both the spacetime path integral approach and the Representation Theory approach. In Sec.III C and IV, we address: Q5: “What is the physical interpretation of SL(3, $\mathbb{Z}$) modular data in 3D?” We use the modular SL(3, $\mathbb{Z}$) data to characterize the braiding-statistics of particles and strings. In Sec.V, we discuss the link and knot patterns of string-braiding systematically, and end with a conclusion. In addition to the main text, we organize the following information in the Supplemental Material: (i) group cohomology and cocycles; (ii) projective representation; (iii) some examples of classification of topological orders; (iv) direct calculations of $\mathbb{S}$, $\mathbb{T}$ using cocycle path integrals.

(NOte: We adopt the name of strings for the vision to incorporate the excitations from both the closed strings (loops) and open strings. Such excitations can have fusion or braiding process. In this work, however, we only focus on the closed string case. Our notation for finite cyclic group is either $\mathbb{Z}_N$ or $\mathbb{Z}_{N}$, though they are equivalent mathematically. We denote $\mathbb{Z}_N$ for the gauge group $G$, the discrete gauge $\mathbb{Z}_N$ flux, or the $\mathbb{Z}_N$ variables, while $\mathbb{Z}_N$ only for the classes of group cohomology or topological order classification. We denote $\gcd(N_i, N_j) \equiv N_{ij}$, $\gcd(N_i, N_j, N_k) \equiv N_{ijk}$, $\gcd(N_i, N_j, N_k, N_l) \equiv N_{ijkl}$, with $\gcd$ stands for the greatest common divisor. We also have $|G|$ as the order of the group, and $\mathbb{F}/\mathbb{Z} \equiv \mathbb{U}(1)$. We may use subindex $n$ for $\omega$, to indicate $n$-cocycle. In principle, we will use types to count the number of cocycles in cohomology groups. But we will use classes to count the number of distinct phases in topological orders. Normally the types overcount the classes. We use the hat symbol $\mathbb{S}$ and $\mathbb{T}$ for the modular matrices acting on the real space in $x, y, z$ directions, so $\mathbb{S}_{xy}^{yz} \cdot (x, y, z) = (z, x, y)$ and $\mathbb{T}_{xy}^{yz} \cdot (x, y, z) = (x + y, y, z)$; while we denote the symbols $\mathbb{S}, \mathbb{T}$ for modular matrices in the quasi-excitations basis.)

II. TWISTED GAUGE THEORY AND COCYCLES OF GROUP COHOMOLOGY

In this section, we aim to address the question:

Q3: “How to formulate or construct certain 3+1D topological orders on the lattice?”

We will consider 3+1D twisted discrete gauge theo-
ries. Our motivation to study the discrete gauge theory is that it is topological and exhibits Aharonov-Bohm phenomena (see Ref. 3 and 43). One approach to formulate a discrete gauge theory is the lattice gauge theory.47 A famous example in both high energy and condensed matter communities is the $Z_2$ discrete gauge theory in 2+1D (or named as $Z_2$ toric code, $Z_2$ spin liquids, $Z_2$ topological order48). Kitaev’s toric code and quantum double model48 provides a simple Hamiltonian,

$$H = -\sum_v A_v - \sum_p B_p,$$

where a space lattice formalism is used, and $A_v$ is the vertex operator acting on the vertex $v$, $B_p$ is the plaquette (or face) term to ensure the zero flux condition on each plaquette. Both $A_v, B_p$ consist of only Pauli spin operators for the $Z_2$ model. Such ground states of the Hamiltonian is found to be $Z_2$ gauge theory with $|G|^2 = 4$-fold topological degeneracy on the $T^2$ torus. Its generalization to a twisted $Z_2$ gauge theory is the $Z_2$ double-semions model, captured by the framework of Levin-Wen string-net model.12,49

### A. Dijkgraaf-Witten topological gauge theory

For a more generic twisted gauge theory, there is indeed another way using the spacetime lattice formalism to construct them by the Dijkgraaf-Witten topological gauge theory.36 There one can formulate the path integral $Z$ (or partition function) of a $(d+1)$D gauge theory ($d$ dimensional space, 1 dimensional time) of a gauge group $G$ as,

$$Z = \sum_{\gamma} e^{iS[\gamma]} = \sum_{\gamma} e^{i2\pi (\omega_{d+1}, \gamma(M_{tri})) (\text{mod } 2\pi)} = \frac{|G|}{|G|^{|N_v|}} \sum_{|g_{ab}|} \prod_{i=1}^d (\omega_{d+1}^{\epsilon_i} (\{g_{ab}\})) |v_a, v_b\rangle \in T_{d+1},$$

where we sum over all mapping $\gamma : M \to BG$, from the spacetime manifold $M$ to $BG$, the classifying space of $G$. In the second equality, we triangulate $M$ to $M_{tri}$ with the edge $[v_a, v_b]$ connecting the vertex $v_a$ to the vertex $v_b$. The action $(\omega_{d+1}, \gamma(M_{tri}))$ evaluates the cocycle $\omega_{d+1}$ on the spacetime $(d+1)$-complex $M_{tri}$. By the relation between the topological cohomology class of $BG$ and the cohomology group of $G$: $H^{d+2}(BG, Z) = H^{d+1}(G, \mathbb{R}/\mathbb{Z})$,36,51 we can simply regard $\omega_{d+1}$ as the $d+1$-cocycles of the cohomology group $H^{d+1}(G, \mathbb{R}/\mathbb{Z})$ (see more details in Appendix A). The group elements $g_{ab}$ are assigned at the edge $[v_a, v_b]$. The $|G|/|G|^{|N_v|}$ factor is to mod out the redundant gauge equivalence configuration, with the number of vertices $N_v$. Another extra $|G|^{-1}$ factor mods out the group elements evolving in the time dimension. The cocycle $\omega_{d+1}$ is evaluated on all the $d+1$-simplex $T_i$ (namely a $d + 2$-cell) triangulation of the spacetime complex. In the case of our 3+1D, we have 4-cocycle $\omega_4$ evaluated at the 4-simplex (or 5-cell) as

$$\omega_4 = \langle g_{01}, g_{12}, g_{23}, g_{34} \rangle. \quad (9)$$

Here the cocycle $\omega_4$ satisfies cocycle condition: $\delta \omega_4 = 1$, which ensures the path integral $Z$ on the 4-sphere $S^4$ (the surface of the 5-ball) will be trivial as 1. This is a feature of topological gauge theory. The $\epsilon$ is the $\pm$ sign of the orientation of 4-simplex, which is determined by the sign of the volume determinant of 4-simplex evaluated by $\epsilon = \text{sgn} (\det (01, 02, 03, 04))$.

We utilize Eq.(8) to calculate the path integral amplitude from an initial state configuration $|\Psi_{in}\rangle$ on the spatial manifold evolving along the time direction to the final state $|\Psi_{out}\rangle$, see Fig.3. In general, the calculation can be done for the mapping class group MCG on any spatial manifold $M_{space}$ as $\text{MCG}(M_{space})$. Here we focus on $M_{space} = T^3$ and $\text{MCG}(T^3) = \text{SL}(3, Z)$, as the modular transformation. We first note that $|\Psi_{in}\rangle = \hat{O}|\Psi_B\rangle$, such a generic $\text{SL}(3, Z)$ transformation $\hat{O}$ under $\text{SL}(3, Z)$ representation can be absolutely generated by $\hat{S}^{xy}$ and $\hat{T}^{xy}$ of Eq.(2),37 thus $\hat{O} = \hat{S}^{xy} \hat{T}^{xy}$. The calculation of the modular $\text{SL}(3, Z)$ transformation from $|\Psi_{in}\rangle$ to $|\Psi_{out}\rangle = |\Psi_A\rangle$ by filling the 4-cocycles $\omega_4$ into the spacetime-complex-triangulation renders the amplitude of the matrix element $O_{(A)(B)}$:

$$O(S^{xy}, T^{xy})_{(A)(B)} = \langle \Psi_A | \hat{O} (S^{xy}, T^{xy}) | \Psi_B \rangle, \quad (10)$$

both space and time are discretely triangulated, so this is a spacetime lattice formalism.

### B. Canonical basis and the generalized twisted quantum double model $D^\omega(G)$ to 3D triple basis

So far we answer the question Q3 using the spacetime-lattice path integral. Our next goal is to construct its Hamiltonian on the space lattice, and to find a good basis representing its quasi-excitations, such that we can efficiently read the information of $O(S^{xy}, T^{xy})$ in this canonical basis. We will outline the twisted quantum double model generalized to 3D as the exactly soluble model in the next subsection, where the canonical basis can diagonalize its Hamiltonian.

**Canonical basis** - For a gauge theory with the gauge group $G$, one may naively think that a good basis for the amplitude Eq.(10) is the group elements $|g_x, g_y, g_z\rangle$, with $g_i \in G$ as the flux labeling three directions of $T^3$. However, this flux-only label $|g_x, g_y\rangle$ is known to be improper on $T^2$ torus already - the canonical basis labeling
particles in 2D is $|\alpha, a\rangle$, requiring both the charge $\alpha$ (as the representation) and the flux $a$ (the group element or the conjugacy class of $G$). We propose the proper way to label excitations for a 3+1D twisted discrete gauge theory for any finite group $G$ in the canonical basis requires one charge $\alpha$ and two fluxes $a, b$:

$$|\alpha, a, b\rangle = \frac{1}{\sqrt{|G|}} \sum_{g_y \in C^a, g_x \in C^b} \operatorname{Tr} \left[ \rho^{a, b}_{\alpha}(g_x) \right] g_x, g_y, g_z. \quad (11)$$

which is the finite group discrete Fourier transformation on $|g_x, g_y, g_z\rangle$. This is a generalization of the 2D result in Ref. 42 and a very recent 3D Abelian case in Ref. 41. Here $\alpha$ is the charge of the representation (Rep) label, which is the $C^{(2)}_{a, b}$ Rep of the centralizers $Z_a, Z_b$ of the conjugacy classes $C^a, C^b$. (For Abelian $G$, the conjugacy class is the group element, and the centralizer is the full $G$.) $C^{(2)}_{a, b}$ Rep means an inequivalent unitary irreducible projective representation of $G$. The $\tilde{\rho}^{a, b}_{\alpha}(c)$ labels this inequivalent unitary irreducible projective $C^{(2)}_{a, b}$ Rep of $G$. The $C^{(2)}_{a, b}$ is an induced 2-cocycle, dimensionally-reduced from the 4-cocycle $\omega_4$. We illustrate $C^{(2)}_{a, b}$ in terms of geometric pictures in Fig. 4. The $\tilde{\rho}^{a, b}_{\alpha}(c)$ are determined as the $C^{(2)}_{a, b}$ projective representation formula:

$$\tilde{\rho}^{a, b}_{\alpha}(c)\tilde{\rho}^{a, b}_{\alpha}(d) = C^{(2)}_{a, b}(c, d)\rho^{a, b}_{\alpha}(cd). \quad (12)$$

The trace term $\operatorname{Tr} \left[ \rho^{a, b}_{\alpha}(g_x) \right]$ is named as the character in the math literature. One can view the charge $\alpha$, along $x$ direction, the flux $a, b$ along the $y, z$. Other details and the calculations of $C^{(2)}_{a, b}$ Rep with many examples can be found in Supplemental Material.

---

FIG. 3. The illustration for $\mathcal{O}_{(A)(B)} = \langle \Psi_A | \hat{O} | \Psi_B \rangle$. The evolution from an initial state configuration $|\Psi_{in}\rangle$ on the spatial manifold (from the top) along the time direction (the dashed line - - - ) to the final state $|\Psi_{out}\rangle$ (on the bottom). For the spatial $T^d$ torus, the mapping class group $\mathrm{MCG}(T^d)$ is the modular $\mathrm{SL}(d, \mathbb{Z})$ transformation. We show schematically the time evolution on the spatial $T^2$, and $T^3$ (shown as $\Pi^2$ attached a $S^1$ circle on each point).

We firstly recall that, in 2D, a reduced 2-cocycle $C_{a}(b, c)$ comes from a slant product $i_{a}\omega(b, c)$ of 3-cocycles, which is geometrically equivalent to filling three 3-cocycles in a triangular prism of Eq. (13). This is known to present the projective representation $\tilde{\rho}^{a}_{\alpha}(b)\tilde{\rho}^{b}_{\alpha}(c) = C_{a}(b, c)\tilde{\rho}^{c}_{\alpha}(bc)$, because the induced 2-cocycle belongs to the second cohomology group $\mathcal{H}^2(G, \mathbb{R}/\mathbb{Z})$. (See its explicit triangulation and a novel use of projective representation in Sec VI.B of Ref. 55.)

Similarly, in 3D, a reduced 2-cocycle $C_{a}(b, c)$ from doing twice of slant products of 4-cocycles forming the geometry of Eq. (14), and renders

$$C^{(2)}_{a, b} = i_b(C_{a}(c, d)) = i_b(i_a\omega(c, d)), \quad (15)$$

present the $C^{(2)}_{a, b}$-projective representation in Eq. (12), which $\tilde{\rho}^{a, b}_{\alpha}(c) : (Z_a, Z_b) \to \mathrm{GL}(Z_a, Z_b)$ can be written as a matrix in the general linear group (GL). This 3D generalization for the canonical basis in Eq. (11) is not only natural, but also consistent to 2D when we turn off the flux along $x$ direction (e.g. set $b = 0$), which reduces 3D’s $|\alpha, a, b\rangle$ to $|\alpha, a\rangle$ of the 2D case.

**Generalizing 2D twisted quantum double model $D^\omega(G)$ to 3D: twisted quantum triple model?** A natural way to combine the Dijkgraaf-Witten theory with Kitaev’s quantum double model Hamiltonian approach will enable us to study the Hamiltonian formalism for the twisted gauge theory, which is achieved in Ref. 50,54 for 2+1D, named as the *twisted quantum double model*. In 2D, the widely-used notation $D^\omega(G)$ implying the twisted quantum double model with its gauge group $G$ and its cocycle twist $\omega$. It is straightforward to generalize their results to 3+1D.

To construct the Hamiltonian on the 3D spatial lattice, we follow Ref. 50 with the form of twisted quantum double model Hamiltonian of Eq. (7) and put the system
on the $T^3$ torus. However, some modification for 3D are adopted: the vertex operator $A_v = [G]^{-1} \sum_{\{v\} = g \in G} A^0_g$ acting on the vertices of the lattice by lifting the vertex point $v$ to $v'$ living in an extra (fourth) dimension as Fig.5, and one computes the 4-cocycle filling amplitude as $Z$ in Eq.(8). A plaquette operator $B_p^{(1)}$ still enforces the zero flux condition on each 2D face (a triangle $p$) spanned by three edges of a triangle. This will ensure the zero flux on each face (along the Wilson loop of a 1-form gauge field). Moreover, zero flux conditions are required if higher form gauge flux are presented. For example, for 2-form field, one shall add an additional $B_p^{(2)}$ to ensure the zero flux on a 3-simplex (a tetrahedron $p$).

Thus, $\sum_p B_p$ in Eq.(7) becomes $\sum_p B_p^{(1)} + \sum_p B_p^{(2)} + \ldots$.

![Fig.5](image)

**FIG. 5.** The vertex operator $A_v$ for the generalized twisted quantum double model in 3D. To evaluate $A_v$, operator acting on the vertex 5, one effectively lifts 5 to 5', and fill 4-cocycles $\omega$ into this geometry to compute the amplitude $Z$ in Eq.(8).

For this specific 3D spatial lattice surrounding vertex 5 by 1, 2, 3, 4 neighbored vertices, there are four 4-cocycles $\omega$ filling in the amplitude of $A_5^{[55]}$.

Analogous to Ref.50, the local operators $A_v$, $B_p$ of the Hamiltonian have nice commuting properties: $[A^0_v, A^0_w] = 0$ if $v \neq u$, $[A^0_v, B_p] = [B_p, A^0_w] = 0$, also $A^0_{v'} = (v') A^0_v$. Notice that $A_p$ defines a ground state projection operator $P_v = |G|^{-1} \sum_g A^0_v$ if we consider a $T^3$ torus triangulated in a cube with only a point $v$ (all eight points are identified). It can be shown that both $A_p$ and $P$ as projection operators projecting other states to the ground state $|\alpha, a, b\rangle$, and $P|\alpha, a, b\rangle = |\alpha, a, b\rangle$ and $A_p|\alpha, a, b\rangle \propto |\alpha, a, b\rangle$. Since $[A^0_v, B_p] = 0$, one can simultaneously diagonalize the Hamiltonian Eq.(7) by this canonical basis $|\alpha, a, b\rangle$ as the ground state basis.

A similar 3D model has been studied recently in Ref.41. There the zero flux condition is imposed in both the vertex operator as well as the plaquette operator. Their Hilbert space thus is more constrained than Ref.50 and ours. However, in the ground state sector, we expect the physics is the same. It is less clear to us whether such a name, twisted quantum double model and its notation $D^d(G)$, are still proper usages in 3D or higher dimensions. With quantum double basis $|\alpha, a\rangle$ in 2D generalized to a triple basis $|\alpha, a, b\rangle$ in 3D, it allures us to call it a twisted quantum triple model in 3D. It awaits mathematicians and mathematical physicists to explore more details in the future.

C. Cocycle of $\mathcal{H}^4(G, \mathbb{R}/\mathbb{Z})$ and its dimensional reduction

To study the twisted gauge theory of a finite Abelian group, we now provide its explicit data of cohomology group and 4-cocycles. Here $\mathcal{H}^{d+1}(G, \mathbb{R}/\mathbb{Z}) = \mathcal{H}^{d+1}(G, U(1))$ by $\mathbb{R}/\mathbb{Z} = U(1)$, as the $(d+1)$th-cohomology group of G over G module U(1). Each class in $\mathcal{H}^{d+1}(G, \mathbb{R}/\mathbb{Z})$ corresponds to a distinct $(d+1)$-cocycle. The different 4-cocycles will label the distinct topological terms of $3+$1D twisted gauge theories. (However, different topological terms may share the same data for topological orders, such as the same modular data $S$ and $T$ and $T'$. Thus different topological terms may describe the same topological order.) The 4-cocycles $\omega_4$ are 4-cocains, but additionally satisfy the cocycle condition $\delta \omega = 1$. The 4-cocain is a mapping $\omega_4(a, b, c, d): (G)^4 \rightarrow U(1)$, which inputs $a, b, c, d \in G$, and outputs a U(1) phase. Furthermore, distinct 4-cococies are not identified by any 4-coboundary $\delta \Omega_3$. (Namely, distinct cocycles $\omega_4$ and $\omega_4'$ do not satisfy $\omega_4/\omega_4' = \delta \Omega_3$ for any 3-cocain $\Omega_3$.) The 4-cocain satisfies the group multiplication rule: $(\omega_4(a, b, c, d)\omega_4'(a, b, c, d))$.

The fourth cohomology group is a kernel of a mapping from $\mathcal{H}^4(G, \mathbb{R}/\mathbb{Z}) = Z^2/\mathbb{Z}^4$. We derive the fourth cohomology group of a generic finite Abelian $G = \prod_{i=1}^k Z_{N_i}$ as $\mathcal{H}^4(G, \mathbb{R}/\mathbb{Z}) = \prod_{1 \leq i < j < k \leq k} (Z_{N_{ij}})^2 \times (Z_{N_{ij}})^2 \times Z_{N_{ijlm}}$. We construct generic 4-cocycles (not identified by 4-coboundaries) for each type, summarized in Table I.

We name the Type II 1st and Type II 2nd 4-cocycles for those with topological term indices: $p_{11(ij)}^{(1st)} \in Z_{N_{ij}}$ and $p_{12(ij)}^{(2nd)} \in Z_{N_{ij}}$ of Eq.(17). There are Type III 1st and Type III 2nd 4-cocycles for topological term indices:

$p_{31(ij)}^{(1st)} \in Z_{N_{ij}}$, and $p_{32(ij)}^{(2nd)} \in Z_{N_{ij}}$. There is also Type IV 4-cocycle topological term index: $p_{41(ijlm)} \in Z_{N_{ijlm}}$.

Since we earlier prelude the relation Eq.(5), $C^{3D} = \oplus_b G^D_b$, between 3D topological orders (described by 4-
We define the reduced form of Type IV \(\omega_4\) in terms of dimensional reduction from 4D topological orders (described by 3-cocycles), it is suggestive to see how the dimensionally-reduced 3-cocycle from 4D gauge theory \(G, \omega\) of Table I. Luckily, the Type II, III \(\omega_4\) flux insertion has twisted \(H^2(G, \mathbb{R}/\mathbb{Z})\) of Eq.(17). The second column shows the topological term indices for 3+1D twisted gauge theory. The slant product \(b_{ijl} \equiv \omega_{ijl}^4(\omega_{ijl}^4)\) is organized in the last column. The third column shows explicit 4-cocycle functions \(\omega_4(a, b, c, d); (G)^4 \to U(1)\). Here \(a = (a_1, a_2, \ldots, a_k)\), with \(a \in G\) and \(a_i \in Z_{N_i}\). (Same notations for \(b, c, d\).) We define the mod \(N_i\) relation by \(c_j + d_j \equiv c_j + d_j \mod N\). The last column shows the induced 3-cocycles from the slant product \(C_b(a, c, d) \equiv i_b \omega_4(a, c, d)\) in terms of Type I, II, III 3-cocycles of \(H^3(G, \mathbb{R}/\mathbb{Z})\) listed in Table XII.

This indeed promisiblly suggests the relation in Eq.(6), \(C^3_{G,\omega_4} \equiv \oplus_b C^3_{G,\omega_4(b)}\), with \(G = G\) the original group. If we view \(b\) as the gauge flux along the \(z\) direction, and compactify \(z\) into a circle, then a single winding around \(z\) acts as a monodromy defect carrying the gauge flux \(b\) (group elements or conjugacy classes).\(^{55,57,58}\) This implies a geometric picture in Fig.7.

One can tentatively write down a relation,
\[
C^3_{G,\omega_4} = \oplus_{b \neq 0} C^2_{G,\omega_4(b)}.
\]

There is a zero flux \(b = 0\) sector \(C^3_{G,\omega_4(b)}\) (with \(\omega_3 = 1\)) where the 2D gauge theory with \(G\) is untwisted. There are other direct sums of \(C^3_{G,\omega_3(b)}\) with nonzero \(b\) flux insertion has twisted \(\omega_3(b)\).

However, different cocycles can represent the same topological order with the equivalent modular data, in the next we should exam this Eq.(19) more carefully not in terms of cocycles, but in terms of the modular data \(S^{xyz}\) and \(T^{xy}\).

### III. REPRESENTATION FOR \(S^{xyz}\) AND \(T^{xy}\)

The modular transformation \(\hat{S}^{xy}\), \(\hat{T}^{xy}\), \(\hat{S}^{xyz}\) of Eq.(2),(3) acts on the 3D real space (see Fig.8) by
\[
\hat{S}^{xy} \cdot (x, y, z) = (-y, x, z),
\]
\[
\hat{T}^{xy} \cdot (x, y, z) = (x + y, y, z),
\]
\[
\hat{S}^{xyz} \cdot (x, y, z) = (z, x, y).
\]

Q4: “What are the generic expressions of \(SL(3, \mathbb{Z})\) modular data?”

In Sec III A, we will first apply the cocycle approach using the spacetime path integral with \(SL(3, \mathbb{Z})\) transfor-
FIG. 8. The modular transformation $SL(2, \mathbb{Z})$ is generated by $\hat{S}^{xy}$ and $T^{xy}$, while the $SL(3, \mathbb{Z})$ is generated by $\hat{S}^{xyz}$ and $T^{xy}$. The dashed arrow $\rightarrow$ stands for the time evolution (as in Fig. 3) from $|\Psi_{\text{in}}\rangle$ to $|\Psi_{\text{out}}\rangle$ under $\hat{S}^{xy}$, $T^{xy}$, $\hat{S}^{xyz}$ respectively. The $\hat{S}^{xy}$ and $T^{xy}$ transformations on a $T^2$ torus’s x-y plane with z direction untouched is equivalent to its transformations on a $T^2$ torus).

A. Path Integral and Cocycle approach

The cocycles approach uses the spacetime lattice formalism, where we triangulate the spacetime complex of a 4-manifold $M = T^3 \times I$, (a $T^3$ torus times a time interval $I$) of Fig. 8 into 4-simplices. We then apply the path integral $Z$ in Eq.(8) and the amplitude form in Eq.(10) to obtain

$$T_{(A)(B)}^{xy} = \langle \Psi_A | \hat{T}^{xy} | \Psi_B \rangle,$$

$$S_{(A)(B)}^{xy} = \langle \Psi_A | \hat{S}^{xy} | \Psi_B \rangle,$$

$$S_{(A)(B)}^{xyz} = \langle \Psi_A | \hat{S}^{xyz} | \Psi_B \rangle,$$

$$\text{GSD} = \text{Tr}[P] = \sum_A \langle \Psi_A | P | \Psi_A \rangle.$$

Here $|\Psi_A\rangle$ and $|\Psi_B\rangle$ are ground state basis on $T^d$ torus, for example, they are $|\alpha, a\rangle$ (with $\alpha$ charge and a flux) in 2+1D and $|\alpha, a, b\rangle$ (with $\alpha$ charge and $a, b$ fluxes) in 3+1D. We also include the data of ground state degeneracy (GSD), where the $P$ is the projection operator to ground states discussed in Sec.II.B. In the case of d-D GSD on $T^d$ (e.g. 3D GSD on $T^3$), we simply compute the $Z$ amplitude filling in $T^d \times S^1 = T^{d+1}$. There is no short cut here except doing explicit calculations.

B. Representation Theory approach

The cocycle approach in Sec.III.A provides nice physical intuitions on the modular transformation process. However, the calculation is tedious. There is a powerful approach simply using Representation Theory, where we will present the general formula of $\hat{S}^{xyz}$, $T^{xy}$, $\hat{S}^{xy}$ data in terms of $(G, \omega, \Delta)$ directly. We outline the three steps:

(i) Obtain the Eq.(15)’s $C_{\alpha,b}^{(2)}$, by doing the slant product twice from 4-cocycle $\omega_4$, or triangulating Eq.13 in Fig.4.

(ii) Derive $\overline{\rho}_{\alpha,b}^{(c)}(c)$ of $C_{\alpha,b}^{(2)}$ projection representation in Eq.(12), which $\overline{\rho}_{\alpha,b}^{(c)}(c)$ is a general linear matrix.

(iii) Write the modular data in the canonical basis $|\alpha, a, b\rangle, |\beta, c, d\rangle$ of Eq.(11).

After some long computations, we find the most general formula $S^{xyz}$ for a group $G$ (both Abelian or non-Abelian) with cocycle twist $\omega_4$:

$$S_{(\alpha, a, b)(\beta, c, d)}^{xyz} = \frac{1}{|G|} \langle \alpha, a, b | \sum_w S_{w}^{xyz} | \beta', c', d' \rangle = \frac{1}{|G|} \sum_{g \in C^a \cap Z_{xy} \cap Z_{xz}} \text{Tr} \overline{\rho}_{\alpha, a, b}^{(c)}(g) \overline{\rho}_{\beta', b, c'}^{(d)}(g) \delta_{g, h_x} \delta_{g, h_y} \delta_{g, h_z}. $$

$$\delta_{g, h} = \delta_{g, h_x} \delta_{g, h_y} \delta_{g, h_z}. $$

We denote $\beta' = \beta_y, d' = d_x$ due to the coordinate identification under $\hat{S}^{xyz}$. The assignment of the directions of gauge fluxes (group elements) are clearly expressed in the second line. We may use the first line expression for simplicity.

We also provide the most general formula of $T^{xy}$ in $|\alpha, a, b\rangle$ basis:

$$T^{xy} = T_{\alpha, a, b} = \frac{\text{Tr} \overline{\rho}_{a, b}^{(c)}(a)}{\dim(a)} = \exp(i \Theta_{\alpha, a, b}).$$

Here $\Theta_{\alpha, a, b}$ is the centralizer of the conjugacy class of $a$. For Abelian $G$, it simplifies to

$$S_{(\alpha, a, b)(\beta, c, d)}^{xyz} = \frac{1}{|G|} \text{Tr} \overline{\rho}_{\alpha, a, b}^{(c)}(a) \text{Tr} \overline{\rho}_{\beta, b, c}^{(d)}(a) \delta_{h, c} = \frac{1}{|G|} S_{\alpha, a, b}^{\beta, c} \delta_{h, c}.$$
Here \( \dim(\alpha) \) means the dimension of the representation, equivalently the rank of the matrix of \( \rho_{\alpha,b}(c) \). Since \( \text{SL}(2, \mathbb{Z}) \) is a subgroup of \( \text{SL}(3, \mathbb{Z}) \), we can express the \( \text{SL}(2, \mathbb{Z}) \)'s \( S^{xy} \) by \( \text{SL}(3, \mathbb{Z}) \)'s \( S^{xyz} \) and \( T^{xy} \) (an expression for both the real spatial basis and the canonical basis):

\[
S^{xy} = ((T^{xy})^{-1}S^{xy})^3(S^{xyz}T^{xy})^2S^{xyz}(T^{xy})^{-1}. \quad (32)
\]

For Abelian \( G \), and when \( C_{\alpha,b}(c,d) \) is a 2-coboundary (cohomologically trivial), the dimensionality of Rep is \( \dim(\text{Rep}) \equiv \dim(\alpha) = 1 \), the \( S^{xy} \) is simplified:

\[
S^{xy}_{(\alpha,a,b)(\beta,c,d)} = \frac{1}{|G|} \frac{\text{tr} \rho_{\alpha,b}(ac^{-1})^* \text{tr} \rho_{\beta,d}(ac^{-1})}{\text{tr} \rho_{\alpha,b}(a) \text{tr} \rho_{\beta,d}(c)} \delta_{b,d}. \quad (33)
\]

We can verify our above results by firstly computing the cocycle path integral approach in Sec.III A, and substitute from the flux basis to the canonical basis by Eq.(11). We have made several consistent checks, by comparing our \( S^{xy} \), \( T^{xy} \), \( S^{xyz} \) to: (1) the known 2D case for the untwisted theory of a non-Abelian group, (2) the recent 3D case for the untwisted theory of a non-Abelian group, (3) the recent 3D case for the twisted theory of a Abelian group. Our expression works for all cases: the (un)twisted theory of (non-)Abelian group. More detailed calculations are reserved in Supplemental Material (Appendix B).

C. Physics of \( S \) and \( T \) in 3D

The \( S^{xy} \) and \( T^{xy} \) in 2D are known to have precise physical meanings. At least for Abelian topological orders, there is no ambiguity that \( S^{xy} \) in the quasiparticle basis provides the mutual statistics of two particles (winding one around the other by \( 2\pi \)), while \( T^{xy} \) in the quasiparticle basis provides the self statistics of two identical particles (winding one around the other by \( \pi \)). Moreover, the intimate spin-statistics relation shows that the statistical phase \( e^{i\Theta} \) gained by interchanging two identical particles is equal to the spin \( s \) by \( e^{2\pi s} \). Fig.9 illustrates the spin-statistics relation. Thus, people also call \( T^{xy} \) as the topological spin of a quasiparticle (\( a, a \)) with charge \( a \) and flux \( a \), in Fig.10(a).

From the 3D viewpoint, however, this \( a, a \) particle is actually a closed string compactified along the compact \( z \) direction. Thus, in Fig.10(b), the self-\( 2\pi \) rotation of the topological spin of a quasiparticle \( (a, a) \) is indeed the self-\( 2\pi \) rotation of a framed closed string. (Physically we understand that there the string can be framed with arrows, because of the inner texture of the string excitations are allowed in a condensed matter system, due to defects or the finite size lattice geometry.) Moreover, from an equivalent 3D view in Fig.10(c), we can view the self-\( 2\pi \) rotation of a framed closed string as the self-\( 2\pi \) flipping of a framed closed string, which flips the string inside-out and then outside-in back to its original status. This picture works for both \( b = 0 \) zero flux sector as well as \( b \neq 0 \) under the background string threading. We thus propose that \( T^{xy}_{b} \) as the topological spin of a framed closed string, threaded by a background string carrying a monodromy \( b \) flux.

1. \( T^{xy}_{b} \) and topological spin of a closed string

We apply the above idea to interpret \( T^{xy}_{b} \), shown in Fig.10. From Eq.(31), we have \( T^{xy}_{b} = T^{xy}_{a,b} \equiv \exp(i\Theta_{a,b}) \) with a fixed \( b \) label for a given \( b \) flux sector. For each \( b \), \( T^{xy}_{b} \) acts as a familiar 2D T matrix \( T^{xy}_{a,b} \), which provides the topological spin of a quasiparticle \( (a, a) \) with charge \( a \) and flux \( a \), in Fig.10(a).

For our case with a gauge group description, the \( b \) (subindex of \( S^{xy}_{b}, T^{xy}_{b}, C^{b}_{D} \)) labels the gauge flux (group element or conjugacy class \( C^{b} \)) winding around the compact \( z \) direction in Fig.1. This \( b \) flux can be viewed as the by-product of a monodromy defect causing a branch cut (a symmetry twist\(^{55,57,58,69} \)), such that the wavefunction will gain a phase by winding around the compact \( z \) direction. Now we further regard the \( b \) flux as a string threading around in the background, so that winding around this background string (e.g. the black string threading in Fig.2(c),10(c),11(c)) gains the \( b \) flux effect if there is a nontrivial winding on the compact direction \( z \). The arrow \( -\leftrightarrow\) along the compact \( z \) schematically indicates such a \( b \) flux effect from the background string threading.

FIG. 9. Both process (a) and (b) starts from creating a pair of particle \( q \) and anti-particle \( \bar{q} \), but the wordlines evolve along time to the bottom differently. The process (a) produces a phase \( e^{i2\pi s} \) due to \( 2\pi \) rotation of \( q \) with spin \( s \). The process (b) produces a phase \( e^{i\Theta} \) due to the exchange statistics. The homotopic equivalence by deformation implies \( e^{i2\pi s} = e^{i\Theta} \).
FIG. 10. Topological spin of (a) a particle by $2\pi$-self rotation in 2D, (b) a framed closed-string by $2\pi$-self rotation in 3D with a compact $z$, (c) a closed-string (blue) by $2\pi$-self flipping, threaded by a background (black) string creating monodromy $b$ flux (along the arrow - - - - -), under a single Hopf link $2_1^2$ configuration. All above equivalent pictures describe the physics of topological spin in terms of $T_{b}^{xy}$. For Abelian topological orders, the spin of an excitation (say A) in Fig.10(a) yields an Abelian phase $e^{i\Theta(A)} = T_{b}^{xy}(A)(A)$ proportional to the diagonal of 2D’s $T_{b}^{xy}$ matrix. The dimensional-extended equivalent picture Fig.10(c) implies that the loop-flipping yields a phase $e^{i\Theta(A),b} = T_{b}^{xy}(A)(A)$ of Eq.(31) (up to a choice of canonical basis), where $b$ is the flux of the black string.

FIG. 11. Exchange statics of (a) two identical particles at positions 1 and 2 by a $\pi$ winding (half-winding), (b) two identical strings by a $\pi$ winding in 3D with a compact $z$, (c) two identical closed-strings (blue) with a $\pi$-winding around, both threaded by a background (black) string creating monodromy $b$ flux, under the Hopf links $2_1^2\#2_1^2$ configuration. Here figures (a)(b)(c) describe the equivalent physics in 3D with a compact $z$ direction. The physics of exchange statics of a closed string turns out to be related to the topological spin of Fig.10, discussed in Sec.III C 3.

2. $S_b^{xy}$ and three-string braiding statistics

Similarly, we apply the same philosophy to do 3D to 2D reduction for $S_b^{xy}$, each effective 2D treading with a distinct gauge flux $b$. We can obtain $S_b^{xy}$ from Eq.(32) with SL(3, $\mathbb{Z}$) modular data. Here we will focus on interpreting $S_b^{xy}$ in the Abelian topological order. Writing $S_b^{xy}$ in the canonical basis $|\alpha, a, b\rangle, |\beta, c, d\rangle$ of Eq.(11), we find that, true for Abelian topological order

$$S_b^{xy} = S_{b(\alpha,a,b)(\beta,c,d)}^{xy} = \frac{1}{|G|} S_{a,c}^{2D \alpha, \beta} \delta_{b,d}. \quad (34)$$

As we predict the generality in Eq.(4), the $S_b^{xy}$ here is diagonalized with the $b$ and $d$ identified (as the $z$-direction flux created by the background string threading). For a given fixed $b$ flux sector, the only free indices are $|\alpha, a\rangle$ and $|\beta, c\rangle$, all collected in $S_{a,c}^{2D \alpha, \beta}$. (Explicit data will be presented in Sec.IV B) Our interpretation is shown in Fig.2. From a 2D viewpoint, $S_b^{xy}$ gives the full $2\pi$ braiding statistics data of two quasiparticle $|\alpha, a\rangle$ and $|\beta, c\rangle$ excitations in Fig.2(a). However, from the 3D viewpoint, the two particles are actually two closed strings compactified along the compact $z$ direction. Thus, the full-$2\pi$ braiding of two particles in Fig.2(a) becomes that of two closed-strings in Fig.2(b). More explicitly, an equivalent 3D view in Fig.2(c), we identify the coordinates $x, y, z$ carefully to see such a full-braiding process is that one (red) string going inside to the loop of another (blue) string, and then going back from the outside.

The above picture again works for both $b = 0$ zero flux sector as well as $b \neq 0$ under the background string threading. When $b \neq 0$, the third (black) background string in Fig.2(c) threading through the two (red, blue) strings. The third (black) string creates the monodromy defect/branch cut on the background, and carrying $b$ flux along $z$ acting on two (red, blue) strings which have non-trivial winding on the third string. This three-string
braiding has been firstly emphasized in a recent paper, here we make further connection to the data $S_{ab}^{xy}$ and understand its physics in a 3D to 2D under $b$ flux sectors.

We have shown and proposed that $S_{ab}^{xy}$ can capture the physics of three-string braiding statistics with two strings threaded by a third background string causing $b$ flux monodromy, where the three strings have the linking configuration as the connected sum of two Hopf links $2_1^1#2_1^1$.

3. Spin-Statistics relation for closed strings

Since a spin-statistics relation for 2D particles is shown by Fig.9. We may wonder, by using our 3D to 2D reduction picture, whether a spin-statistics relation for a closed string holds?

To answer this question, we should compare the topological spin picture of $T_{ab}^{xy} = T_{\alpha x}^{a y, b y} = \exp(i\theta_{\alpha x, b y})$ to the exchange statistic picture of two closed strings in Fig.11. Fig.11 essentially takes a half-braiding of the $S_{ab}^{xy}$ process of Fig.2, and considers doing half-braiding on the same excitations in $\{a, b\} = \{\beta, c, d\}$. In principle, one can generalize the framed worldline picture of particles in Fig.9 to the framed worldsheet picture of closed-strings. (ps. The framed worldline is like a worldsheet, the framed worldsheet is like a worldvolume.) Such an interpretation shows that the topological spin of Fig.10 and the exchange statistics of Fig.11 carry the same data, namely

$$T_{ab}^{xy} = T_{\alpha x}^{a y, b y} = (S_{a y, a y}^{2D, x, y})_{\beta}^{1} \text{ or } (S_{a y, a y}^{2D, x, y})_{\beta}^{1} \times \ast (35)$$

from the data of Eq.(31),(34). The equivalence holds, up to a (complex conjugate $\ast$) sign caused by the orientation of the rotation and the exchange.

In Sec.(IV B), we will show, for the twisted gauge theory of Abelian topological orders, such an interpretation Eq.35 is correct and agrees with our data. We shall name this as the spin-statistics relation for a closed string.

In this section, we have obtained the explicit formulas of $S_{xy}^{x y}, T_{xy}^{xy}$ in Sec.III A, III B, and as well as captured the physical meanings of $S_{ab}^{xy}, T_{ab}^{xy}$ in Sec.III C. Before concluding, we note that the full understanding of $S_{xy}^{x y}$ seems to be intriguingly related to the 3D nature. It is not obvious to us that the use of 3D to 2D reduction can capture all physics of $S_{xy}^{x y}$. We will come back to comment this issue in the Sec.V.

IV. $SL(3, Z)$ MODULAR DATA AND MULTI-STRING BRAIDING

A. Ground state degeneracy and Particle, String types

We now proceed to study the topology-dependent ground state degeneracy (GSD), modular data $S$, $T$ of 3+1D twisted gauge theory with finite group $G = \prod_i Z_{N_i}$. We shall comment that the GSD on $T^2$ of 2D topological order counts the number of quasi-particle excitations, which from the Representation (Rep) Theory is simply counting the number of charges $\alpha$ and fluxes $\beta$ forming the quasi-particle basis $|\alpha, \beta\rangle$ spanned the ground state Hilbert space. In 2D, GSD counts the number of types of quasi-particles (or anyons) as well as the number of basis $|\alpha, \beta\rangle$. For higher dimension, GSD on $T^d$ of $d$-D topological order still counts the number of canonical basis $|\alpha, a, b, \ldots\rangle$, however, may over count the number of types of particles (with charge), strings (with flux), etc excitations. From a untwisted $Z_N$ field theory perspective, the fluxed string may be described by a 2-form $B$ field, and the charged particle may be described by a 1-form $A$ field, with a BF action $\int B dA$. As we can see the fluxes $a, b$ are over-counted.

We suggest that to count the number of types of particles of $d$-D is equivalent to Fig.12 process, where we dig a ball $B^d$ with a sphere $S^{d-1}$ around the particle $q$, which resides on $S^d$. And we connect it through a $S^1$ tunnel to its anti-particle $\bar{q}$. This process causes creation-annihilation from vacuum, and counts how many types of $q$ sectors is equivalent to:

$$\text{the number of particle types} = \text{GSD on } S^{d-1} \times I(36)$$

with $I \simeq S^1$ for this example. For spacetime integral, one evaluates Eq.(29) on $M = S^{d-1} \times S^1 \times S^1$.

For counting closed string excitations, one may naively use $T^2$ to enclose a string as analogous to use $S^2$ to enclose a particle in 3D. Then, one may deduce the number of string types $= \text{GSD on } T^2 \times S^1 \simeq T^3$, and that of spacetime integral on $T^4$, as we already mentioned earlier which is incorrect and overcounting. We suggest, the number of string types $= S^{x y}, T^{x y}$’s number of blocks, (37)

which block is labeled by $b$ as the form of Eq.4. We will show the counting by Eq.(36), (37) in explicit examples in the next.
B. Abelian examples: 3D twisted $Z_{N_1} \times Z_{N_2} \times Z_{N_3}$ gauge theories with Type II, III 4-cocycles

We firstly study the most generic 3+1D finite Abelian twisted gauge theories with Type II, III 4-cocycle twists in Table I. It is general enough for us to consider twisted gauge theories with Type II, III 4-cocycle twists in the canonical basis $|\alpha, a, b\rangle$ (GSD on $\mathbb{T}^3$) counts twice the flux sectors. In Table II, we show their $S^{xyz}$ by computing Eq.(30), where we denote $a = (a_1, a_2, a_3, \ldots)$, with $a_j \in Z_{N_j}$, and the same notation for other $b, c, d$ fluxes:

$$S^{xyz}_{\alpha, a, b} = \frac{1}{|G|} S_{\alpha, a, b}^{\alpha, \beta} \delta_{\alpha, \beta}.$$  

The $S$-matrix reads $g_{xk} = d_k$, $g_{yk} = a_k$ in Eq.(30).

Here we extract the $S_{d, a, b}^{\alpha, \beta}$ part of $S^{xyz}$ ignoring the $|G|^{-1}$ factor:

$$S^{xyz} = S_{(\alpha, a, b)(\beta, c, d)}^{xyz} = \frac{1}{|G|} S_{d, a, b}^{\alpha, \beta} \delta_{\alpha, \beta}. \quad (38)$$

The $S$-matrix reads $g_{xk} = d_k$, $g_{yk} = a_k$ in Eq.(30).

In Table III, we show $T^{xy}$. Here for Abelian $G$, with $C_{a, b}^{(2)}(c, d)$ is a 2-coboundary (cohomologically trivial) thus dim(Rep) = 1, we compute $S^{xy}$ by Eq.(33) and that reduces to Eq.(34) $S^{xy} = S^{xyz}_{(\alpha, a, b)(\beta, c, d)} = \frac{1}{|G|} S^{2D}_{d, a, b} \delta_{\alpha, \beta}$. In Table IV, we show $S^{xy}$ in terms of $S^{2D}_{a, c}(b)$ for simplicity.

| $H^3(G, \mathbb{R}/\mathbb{Z})$ | 4-cocycle | $\alpha, \beta$ | Induced $T^{xy}_{\alpha, \beta}$ |
|--------------------------|-----------|----------------|-------------------------|
| $Z_{N_{12}}$ Type II 1st | $\exp \left( \sum_{k} 2\pi i N_{12} \left( \beta_{k} a_{k} - \alpha_{k} d_{k} \right) \right) \cdot \exp \left( 2\pi i \frac{|N_{12}|}{\pi N_{2}} \left( a_{1} d_{2} + a_{2} d_{1} - 2a_{1} b_{1} d_{2} \right) \right)$ | Type I, II of $H^3$ |
| $Z_{N_{12}}$ Type II 2nd | $\exp \left( \sum_{k} 2\pi i N_{12} \left( \beta_{k} a_{k} - \alpha_{k} d_{k} \right) \right) \cdot \exp \left( 2\pi i \frac{|N_{12}|}{\pi N_{2}} \left( a_{1} d_{2} + a_{2} d_{1} - 2a_{1} b_{1} d_{2} \right) \right)$ | Type I, II of $H^3$ |
| $Z_{N_{123}}$ Type III 1st | $\exp \left( \sum_{k} 2\pi i N_{123} \left( \beta_{k} a_{k} - \alpha_{k} d_{k} \right) \right) \cdot \exp \left( 2\pi i \frac{|N_{123}|}{\pi N_{2} N_{3}} \left( a_{1} d_{2} + a_{2} d_{1} - 2a_{1} b_{1} d_{2} \right) \right)$ | Two Type IIs of $H^3$ |
| $Z_{N_{123}}$ Type III 2nd | $\exp \left( \sum_{k} 2\pi i N_{123} \left( \beta_{k} a_{k} - \alpha_{k} d_{k} \right) \right) \cdot \exp \left( 2\pi i \frac{|N_{123}|}{\pi N_{2} N_{3}} \left( a_{1} d_{2} + a_{2} d_{1} - 2a_{1} b_{1} d_{2} \right) \right)$ | Two Type IIs of $H^3$ |

**TABLE III.** $T^{xy}$ modular data of the 3+1D twisted gauge theories with $G = Z_{N_1} \times Z_{N_2} \times Z_{N_3}$. We can view this in terms of the index $b$ for blocks of $T^{xy}_{\alpha, \beta} = T^{xy}_{a_1 b, a_2 b, a_3 b}$, with the flux $b$ along the compact $z$ direction.

Several remarks follow:

1. For an untwisted gauge theory (topological term
TABLE IV. $S^g$ modular data of the 3+1D twisted gauge theories with $G = Z_{N_1} \times Z_{N_2} \times Z_{N_3}$. There are two more columns ($\mathcal{H}^3(G, \mathbb{R}/\mathbb{Z})$, induced $S^g_{\text{toric}}$) not shown here, since the data simply duplicates Table II’s first and fourth column. The basis chosen here is not canonical for excitations, in the sense that particle braiding around trivial vacuum still gain a non-trivial statistic phase. Finding the proper canonical basis for each $b$ block of $S^g_{\text{toric}}$ can be done by Ref.62’s method.

\[
\omega_4 \rightarrow S^{2D}_{\alpha,b}(c) = \text{tr} \rho^{a,b}_{\alpha}(a^2 c^{-1}) \cdot \text{tr} \rho^{a,b}_{\beta}(ac^{-2})
\]

| II 1st     | $\exp \left( \sum_{k} \frac{\pi}{N_k} (\alpha_k (c_k - 2a_k) + \beta_k (a_k - 2c_k)) \right) \cdot \exp \left( \frac{2 \pi i (\alpha b_1 + \beta b_2)}{N_k (N_k^2 - N_k)} b_1 (2a_1 a_2 - 2a_2^2 - 2c_2^2) + b_2 (2a_1 a_2 + 2c_1 c_2 - a_1 c_2 - a_2 c_1) \right)$ |
| II 2nd     | $\exp \left( \sum_{k} \frac{\pi}{N_k} (\alpha_k (c_k - 2a_k) + \beta_k (a_k - 2c_k)) \right) \cdot \exp \left( \frac{2 \pi i (\alpha b_1 + \beta b_2)}{N_k (N_k^2 - N_k)} b_2 (2a_1 c_1 - 2a_1^2 - 2c_1^2) + b_1 (2a_1 a_2 + 2c_1 c_2 - a_1 c_2 - a_2 c_1) \right)$ |
| III 1st    | $\exp \left( \sum_{k} \frac{2 \pi i}{N_k} (\alpha_k (c_k - 2a_k) + \beta_k (a_k - 2c_k)) \right) \cdot \exp \left( \frac{2 \pi i (\alpha b_1 + \beta b_2)}{N_k (N_k^2 - N_k)} b_1 (2a_2 c_3 + a_2 c_3 - 2a_2 c_3 - 2a_2 c_3) + b_2 (2a_1 a_3 + 2c_1 c_3 - a_1 c_3 - a_3 c_1) \right)$ |
| III 2nd    | $\exp \left( \sum_{k} \frac{2 \pi i}{N_k} (\alpha_k (c_k - 2a_k) + \beta_k (a_k - 2c_k)) \right) \cdot \exp \left( \frac{2 \pi i (\alpha b_1 + \beta b_2)}{N_k (N_k^2 - N_k)} b_3 (a_1 c_2 + a_2 c_1 - 2a_1 a_2 - 2c_1 c_2) + b_1 (2a_3 a_2 + 2c_3 c_2 - a_3 c_2 - a_2 c_3) \right)$ |

The implication of classification. Let us do the counting of number of phases in the simplest example of Type II, $G = Z_2 \times Z_2$ twisted theory. There are four types in $\mathcal{H}^3(G, \mathbb{R}/\mathbb{Z})$. However, we find there are only two distinct topological orders out of four. One is the trivial $(Z_2)^2$ gauge theory as Eq.(39), the other is the nontrivial type as Eq.(40). There are two ways to see this, (i) from the full $S^{xy}$, $T^{xy}$ data. (ii) viewing the sector of $S^g_{\text{toric}}$, $T^g_{\text{toric}}$ under distinct fluxes $b$, which is from a $\mathcal{H}^3(G, \mathbb{R}/\mathbb{Z})$ perspective. We should beware that in principle tagging particles, strings or gauge groups is not allowed, so one can identify many seemingly different orders by relabeling their excitations. We will give more examples of counting 2D, 3D topological orders in Appendix A.

(6) Spin-statistics relation of closed strings in Eq.(35) is verified to be correct here, while we take the complex conjugate in Eq.(35). This is why we draw the orientation of Fig.10,11 oppositely. Interpreting $T^{xy}$ as the topological spin also holds.

(7) Cyclic relation for $S^{xy}$ in 3D: For all above data (Type II, Type III), there is a special cyclic relation when the charge labels are equal $\alpha = \beta$ for $S^{a,b}_g$ (e.g. for pure fluxes $\alpha = \beta = 0$, namely for pure strings):

$$S^{a,b}_g \cdot S^{b,a}_g = 1. \quad (41)$$

However, such a cyclic relation does not hold (even at the zero charge) for $S^{2D}_{\alpha,b}$, namely $S^{2D}_{\alpha,b} \cdot S^{2D}_{\alpha,b}$, $S^{2D}_{\alpha,b} \cdot S^{2D}_{\alpha,b} \neq 1$ in general. Some other cyclic relations are studied recently in Ref.40 and 41, for which we have not yet made detailed comparisons but the perspectives may be different. In Ref.41, their cyclic relation is determined by triple linking numbers associated with the membrane operators. In Ref.40, their cyclic relation is related to the loop braiding of Fig.2, which has its relevancy instead to $S^{2D}_{\alpha,b}$, not our cyclic relation of $S^{a,b}_g$ for 3D. We will comment more about the difference and the subtlety of $S^{xy}$ and $S^{gxy}$ in Sec.V.B.

(2) Both $S^{xy}$, $T^{xy}$ have block diagonal forms as $S^{xy}_b$, $T^{xy}_b$ respect to the $b$ flux (along $z$) correctly reflects what Eq.(4) precludes already.

(3) $T^{xy}$ is in SL(3, $Z$) canonical basis automatically and full-diagonal, but $S^{xy}$ may not be in the canonical basis for each blocks of $S^{xy}_b$, due to its SL(2, $Z$) nature. We can find the proper basis in each $b$ block by the canonical method. Nevertheless, the eigenvalues of $S^{xy}$ in Table IV are still proper and invariant regardless any basis.

(4) Characterization of topological orders: We can further compare the 3D $S^{gxy}_b$ data to SL(2, $Z$)’s data of 2D $S^{gxy}$ of $\mathcal{H}^3(G, \mathbb{R}/\mathbb{Z})$ in Table XII, (see Appendix A for data) All of the dimensional reduction of these data ($S^{gxy}_b$ in Table II, IV, and $T^{gxy}_b$ in Table III) agree with 3-cocycle (induced from 4-cocycle $\omega_4$) in Table I’s last column. Gathering all data, we conclude that Eq.(19) becomes explicitly. For example, Type II twists for $G = (Z_2)^2$ as,

$$C^{3D}_{(Z_2)^2,1} = 4C^{2D}_{(Z_2)^2,1} \quad \text{(39)}$$

$$C^{3D}_{(Z_2)^2,\omega_{4,11}} = C^{2D}_{(Z_2)^2} \otimes C^{2D}_{(Z_2)^2,\omega_{3,11}} + 2C^{2D}_{(Z_2)^2,\omega_{3,11}} \quad \text{(40)}$$

Such a Type II $\omega_{4,11}$ can produce a $b = 0$ sector of $(Z_2$ toric code $\otimes Z_2$ toric code) of 2D as $C^{2D}_{(Z_2)^2}$, some $b \neq 0$ sector of $(Z_2$ double-7emions $\otimes Z_2$ toric code) as $C^{2D}_{(Z_2)^2,\omega_{3,11}}$, and another $b \neq 0$ sector $C^{2D}_{(Z_2)^2,\omega_{3,11}}$ for example. This procedure can be applied to all other types of cocycle twists.

(5) Classification of topological orders: We shall interpret the decomposition in Eq.(19) as the
C. Non-Abelian examples: 3D twisted \((Z_n)^3\) gauge theories with Type IV 4-cocycle

We now study a more interesting example, a generic 3+1D finite Abelian twisted gauge theory with Type IV 4-cocycle twists with \(p_{ijklm} \neq 0\) in Table I. For generality, we have also incorporated Type IV twists together with the aforementioned Type II, III twists. So all 4-cocycle twists will be discussed in this subsection. Differ from the previous example in Sec.IV B of Abelian topological order with Abelian statistics, we will show the contribution from (non-)Abelian excitations. From shall explain our notation in Eq.(43), the \((n)\) Abelian gauge theories, and \(n^{20} \cdot (n - 1)\) statistics.

Ground state degeneracy (GSD)-

We compute the GSD of gauge theories with a Type IV twist on the spatial \(\mathbb{T}^3\) torus, truncated from \(|G|^3 = |n|^3 = n^{12}\) to:

\[
\text{GSD}_{\mathbb{T}^3, IV} = (n^8 + n^9 - n^5) + (n^{10} - n^7 - n^6 + n^3) \equiv \text{GSD}^{Abel}_{\mathbb{T}^3, IV} + \text{GSD}^{nAbel}_{\mathbb{T}^3, IV}. \tag{42}
\]

We derive the above only for a prime \(n\). The GSD truncation is less severe and is in between \text{GSD}_{\mathbb{T}^3, IV} and \(|G|^3\) for non-prime.) As such the canonical basis \((\alpha, a, b)\) of the ground state sector on \(\mathbb{T}^3\) no longer have \(|G|^3\) labels with the \(|G|\) number charge and two pairs of \(|G|\) number of fluxes as Sec.IV B. This truncation is due to the nature of non-Abelian physics of Type IV \(\omega_{4, IV}\) twisted. We shall explain our notation in Eq.(43), the \((n)\) Abel means the contribution from (non-)Abelian excitations. From the Rep Theory viewpoint, we can recover the truncation back to \(|G|^3\) by carefully reconstructing the quantum dimension of excitations. We obtain

\[
|G|^3 = \left( \text{GSD}^{Abel}_{\mathbb{T}^3, IV} \right) + \left( \text{GSD}^{nAbel}_{\mathbb{T}^3, IV} \right) \cdot n^2 \tag{44}
\]

\[
= \left\{ n^4 + n^5 - n^7 \right\} \cdot n^4 \cdot (1)^2
+ \left\{ n^4 - n^5 - n^4 \right\} \cdot n^2 \cdot (n)^2
= \left\{ \text{Flux}^{Abel}_{IV} \right\} \cdot n^4 \cdot (\text{dim}_{1})^2 + \left\{ \text{Flux}^{nAbel}_{IV} \right\} \cdot n^2 \cdot (\text{dim}_{n})^2
\]

The \text{dim}_{m} means the dimension of Rep as \text{dim}(Rep) is \(m\), which is also the quantum dimension of excitations. Here we have a dimension 1 for Abelian and \(n\) for non-Abelian. In summary, we understand the decomposition precisely in terms of each (non-)Abelian contribution by

\[
\begin{align*}
\text{flux sectors} = |G|^2 = |n|^2 = \text{Flux}^{Abel}_{IV} + \text{Flux}^{nAbel}_{IV} \\
\text{GSD}_{\mathbb{T}^3, IV} = \text{GSD}^{Abel}_{\mathbb{T}^3, IV} + \text{GSD}^{nAbel}_{\mathbb{T}^3, IV} \\
\text{dim}(\text{Rep})^2 = n^2, n^2
\end{align*}
\tag{45}
\]

Actually, the canonical basis \((\alpha, a, b)\) (GSD on \(\mathbb{T}^3\)) still works, the sum of Abelian \text{Flux}^{Abel}_{IV} and non-Abelian \text{Flux}^{nAbel}_{IV} counts the flux number of \(a, b\) as the unaltered \(|G|^2\). The charge Rep \(\alpha\) is unchanged with a number of \(|G| = n^4\) for Abelian sector with a rank-1 matrix (1-dim linear or projective) representation, however, the charge Rep \(\alpha\) is truncated to a smaller number \(n^2\) for non-Abelian sector also with a larger rank-\(n\) matrix (\(n\)-dim projective) representation.

Another view on GSD in \(\mathbb{T}^3, IV\) can be inspired by a generic formula like Eq.(4)

\[
\text{GSD}_{\mathbb{T}^3, IV} = \oplus_b \text{GSD}_{b, M'} = \sum_b \text{GSD}_{b, M'}, \tag{46}
\]

where we sum over GSD in all different \(b\) flux sectors, with \(b\) flux along \(S^1\). Here we can take \(M' \times S^3 = \mathbb{T}^3\) and \(M' = \mathbb{T}^2\). For non-Type IV (untwisted, Type II, III) \(\omega_4\) case, we have \(|G|\) sectors of \(b\) flux and each has \(\text{GSD}_{b, \mathbb{T}^3} = |G|^2\). For Type IV \(\omega_4\) case \(|G| = (Z_n)^4\) with a prime \(n\), we have

\[
\text{GSD}_{\mathbb{T}^3, IV} = |G|^2 + (|G| - 1) \cdot |Z_n|^2 \cdot (1 \cdot |Z_n|^3 + (|Z_n|^2 - 1) \cdot n),
\]

\[
n^8 + (n^4 - 1) \cdot n^2 \cdot (1 \cdot n^3 + (n^3 - 1) \cdot n). \tag{47}
\]

As we expect, the first part is from the zero flux \(b = 0\), which is the normal untwisted 2+1D \((Z_n)^4\) gauge theory (toric code) as \(C^{2D}_{(Z_n)^4}\) with \(|G|^2 = n^8\) on 2-torus. The remained \((|G| - 1)^2\) copies are inserted with nonzero flux \((b \neq 0)\) as \(C^{2D}_{(Z_n)^4, \omega_3}\) with Type III 3-cocycle twists of Table XII. In some case but not all cases, \(c^{2D}_{(Z,n), \omega_3}\) is \(C^{2D}_{(Z_n)^3, \omega_3}\). In either case, the GSD \(\mathbb{T}^3, IV\) for \(b \neq 0\) has the same decomposition always equivalent to a untwisted \(Z_n\) gauge theory with \(\text{GSD}_{\mathbb{T}^2} = n^2\) direct product with

\[
\text{GSD}_{\mathbb{T}^2, \omega_3, III} = (1 \cdot n^3 + (n^3 - 1) \cdot n) \tag{48}
\]

\[
\equiv \text{GSD}^{Abel}_{\mathbb{T}^2, \omega_3, III} + \text{GSD}^{nAbel}_{\mathbb{T}^2, \omega_3, III}.
\tag{49}
\]

which we generalize the result derived for 2+1D Type III \(\omega_3\) twisted with \(G = (Z_3)^2\) in Ref.42 to \(G = (Z_n)^3\) of a prime \(n\). One can repeat the counting for 2+1D as Eq.(44)(45), see Appendix A.

To summarize, from the GSD counting, we already foresee there exist non-Abelian strings in 3+1D Type IV twisted gauge theory, with a quantum dimension \(n\). Those non-Abelian strings (fluxes) carries \text{dim}(Rep) = \(n\) non-Abelian charges. Since charges are sourced by particles, those non-Abelian strings are not pure strings but attached with non-Abelian
particles. (For a projection perspective from 3D to 2D, a nonAbelain string of \(C_{3D}^{\text{2D}}\) is a non-Abelian dyon with both charge and flux of \(C_{\text{2D}}^{\text{2D}}\).)

**Modular \(T^{xy}\) of 3D-**

We shall compute \(T^{xy}, S^{xy}\) using the formula derived in Sec.III.B for Type IV \(\omega_{3}\) theory (for generality, we also include the twists by Type II, III \(\omega_{2}\)). Due to the large GSD and the quantum dimension of non-Abelian nature, we focus on a simplest example \(G = (Z_{2})^{4}\) theory to have the smallest amount of data. By \(\mathcal{H}^{4}(G; \mathbb{R}/\mathbb{Z}) = Z_{2}^{2}\), we have \(2^{21}\) types of theories, where \(2^{20}\) types with Type IV are endorsed with non-Abelian statistics. (While \(2^{20}\) types are Abelian gauge theories of non-Type IV have their T,S data in Sec.IV.B.) For \(G = (Z_{2})^{4}\), there are still GSD\(T_{4},S_{1}\) = 1576. Thus both T and S are matrices with the rank 1576. \(T^{xy}\) has 1576 components along diagonal.

For \(G = (Z_{2})^{4}\), we firstly define a quantity \(\eta_{g_{1},g_{2},g_{3}}\) of convenience from the \(C_{a,b}^{(2)}(c,d)\) in Eq.(15),

\[
\eta_{g_{1},g_{2},g_{3}} = \begin{cases} 
0, & \text{if } C_{a,b}^{(2)}(g_{3}, g_{3}) = +1 \\
1, & \text{if } C_{a,b}^{(2)}(g_{3}, g_{3}) = -1 
\end{cases} 
\]  

(50)

Below the \(p_{lm}, p_{l,mn}\) are the shorthand of Type II, III (both 1st, 2nd) topological term labels, the \(p_{lm}f_{lm}(a,b,c), p_{l,mn}f_{lm}(a,b,c)\) abbreviate the function forms in the exponents of Type II, III \(\omega_{t}\) in Table I. Namely, we regard their 4-cocycle \(\omega_{4}(a,b,c,d)\) as a trivial 2-cocycle \(c_{a,b,c}(d)\) written as \(c_{a,b,c}(d) = \eta_{a,b,c}(d)\), where \(\eta_{a,b,c}(d)\) is a 1-cochain: \(\eta_{a,b,c}(d) = \exp(i p_{lm}f_{lm}(a,b,c)) = \exp(\frac{2\pi i}{N_{m}N_{n}p_{lm}a_{m}b_{m}c_{m}})\) for Type II case. \(\eta_{a,b,c}(d) = \exp(\frac{2\pi i}{N_{m}N_{n}p_{l,m}a_{m}b_{m}c_{m}})\) for Type III case. We derive \(T^{xy} = T_{a,b,c}^{xy}\) of Eq.(31) in Table V.

\[
\begin{array}{c|c|c}
\text{Excitations } (\alpha, \alpha, \beta) & \text{Flux } F = \sum_{i=1}^{N_{c}} (\pm i)(\alpha, \alpha, \beta) & \text{Topological Basis } T_{\alpha,\beta}^{\text{Here}} \\
(\alpha, F(j_{\text{Abel}})) & \exp(\sum_{l,m,n}^{1} \pm i \alpha_{l} \alpha_{m} \alpha_{n}) & \text{e.g. } \pm 1 \\
((\pm a_{u}, \pm b_{v}), F(j_{\text{Abel}})) & \exp(\sum_{l,m,n}^{1} \pm i \alpha_{l} \alpha_{m} \alpha_{n}) & \text{e.g. } \pm 1 \text{ or } \pm i
\end{array}
\]

TABLE II: SL(3, \(\mathbb{Z}\)) modular data \(T^{xy} = T_{a,b,c}^{xy}\) for \((Z_{2})^{4}\) theory with Type IV \(\omega^{4}\). The formula of \(T^{xy}\) is separated to two sets: the first set with 736 components (from the sector GSD\(T_{4},S_{1}\)) and another 840 components (from the sector GSD\(T_{3},S_{1}\)). \(F = (a_{u}, b_{v})\) are flux with 8 components, \((a_{1}, a_{2}, a_{3}, a_{4},) \in (Z_{2})^{4}\). The number of distinct fluxes in \(F(j_{\text{Abel}}) = 46\) (\(= \text{Flux}_{\text{Abel}}^{\text{4D}}\)), the number of distinct fluxes \(F(j_{\text{Abel}}) = 210\) (\(= \text{Flux}_{\text{Abel}}^{\text{4D}}\)). This table contains all \(2^{20}\) kinds of \(T^{xy}\) for the non-Abelian theories in \(\mathcal{H}^{4}(G; \mathbb{R}/\mathbb{Z}) = Z_{2}^{2}\) (half of \(2^{21}\)). (\((\pm a_{u}, \pm b_{v})\) pair makes up the numbers of charge Rep \(n^{2} = 2^{3}\) in Eq.(45). Details of the rank 2 matrix Rep is shown in Appendix A.

**Modular \(S^{xy}\) of 3D-**

The \(S^{xy}\) matrix has \(1576 \times 1576\) components. We organize \(S^{xy}\) into four blocks, denoting \((n)\text{Abel}\) for (non)Abelian with 736 (840) components. Defining \(S_{(a,b,a), (b,c,d)}^{xy} = \frac{1}{|G|} S_{a,b,d}^{\text{Abel}} \delta_{b,c}\), we obtain

\[
S^{xy} = \frac{1}{|G|}
\begin{pmatrix}
S_{\text{Abel}, \text{Abel}} & S_{\text{Abel}, n\text{Abel}} \\
S_{n\text{Abel}, \text{Abel}} & S_{n\text{Abel}, n\text{Abel}}
\end{pmatrix}
\]

\[
S_{\text{Abel}, \text{Abel}} = 1 \cdot \exp(\sum_{k}^{N_{k}} (-\alpha_{k} d_{k} + \beta_{k} a_{k}))\cdot \delta_{b,c},
\]

\[
S_{\text{Abel}, n\text{Abel}} = 2 \cdot (-1)(-\alpha_{k} d_{k})\cdot \exp(\sum_{l,m,n}^{1} \pm i \alpha_{l} \alpha_{m} \alpha_{n})\cdot \delta_{b,c},
\]

\[
S_{n\text{Abel}, \text{Abel}} = 2 \cdot (-1)(\beta_{k} a_{k})\cdot \exp(\sum_{l,m,n}^{1} \pm i \alpha_{l} \alpha_{m} \alpha_{n})\cdot \delta_{b,c},
\]

\[
S_{n\text{Abel}, n\text{Abel}} = 4 \cdot \exp(\sum_{l,m,n}^{1} \pm i \alpha_{l} \alpha_{m} \alpha_{n})\cdot \delta_{b,c}.
\]

The \(\exp(\sum_{k}^{N_{k}} (-\alpha_{k} d_{k} + \beta_{k} a_{k}))\) factor in the top-left block shows the pure-particle pure-string braiding of un-
Some remarks follow:

(1) Dimensional reduction from 3D to 2D sectors with \( b \) flux: From the above \( S^{xy} \), \( T^{xy} \), there is no difficulty to derive \( S^{xy} \) from Eq.(32). From all these modular data \( S^{xy}_b, T^{xy}_b \) data, we find consistency with the dimensional reduction of 3D topological order by comparing with induced 3-cocycle \( \omega_3 \) from \( \omega_1 \). Let us consider a single specific example, given the Type IV with induced 3-cocycle \( S \) from \( (1) \).

The \( C_{(Z_2)^4}^{2D} \), again is the normal \( (Z_2)^4 \) gauge theory at \( b = 0 \). The 10 copies of \( C_{(Z_2)^4}^{2D} \) with a untwisted dihedral \( D_4 \) gauge theory \( (|D_4| = 8) \) product with the normal \( (Z_2) \) gauge theory. The duality to \( D_4 \) theory in 2D can be expected, see Table VI. (For a byproduct of our work, we go beyond Ref.42 to give the complete classification of all twisted 2D \( \omega_3 \) of \( G = (Z_2)^3 \) and their corresponding topological orders and twisted quantum double \( D^*G \) in Appendix A.) The remained 5 copies \( C_{(Z_2)^3}^{2D} \), \( \omega_1,\omega_3,\omega_1,\omega_3,\omega_3 \) must contain the twist on the full group \( (Z_2)^4 \), not just its subgroup. This peculiar feature suggests the following remark.

(2) Sometimes there may exist a duality between a twisted Abelian gauge theory and a untwisted non-Abelian gauge theory, one may wonder whether one can find a dual non-Abelian gauge theory for \( C_{(Z_2)^4}^{2D} \). We find that, however, \( C_{(Z_2)^4}^{2D} \) cannot be dual to a normal gauge theory (neither Abelian nor non-Abelian), but must be a twisted (Abelian or non-Abelian) gauge theory. The reason is more involved. Let us firstly recall the more familiar 2D case. One can consider \( G = (Z_2)^3 \) example with \( C_{(Z_2)^3}^{2D} \), with \( H^3(G, \mathbb{Z}/2) = (Z_2)^7 \). There are \( 2^6 \) for non-Abelian types with Type III \( \omega_3 \) (the other \( 2^6 \) Abelian without of Type III \( \omega_3 \). We find the 64 non-Abelian types of 3-cocycles \( \omega_3 \) go to 5 classes labeled \( \omega_3[1], \omega_3[3d], \omega_3[3i], \omega_3[5] \), and \( \omega_3[7] \), and their twisted quantum double model \( D^*G \) are shown in Table VI. The number in the bracket \([..]\) is related to the number of pairs of \( \pm i \) in the T matrix and the \( d/i \) stand for the linear dependence(\( d \)/independence(\( i \)) of fluxes generating cocycles.

| \( \omega_3[1] \) | Twisted quantum double \( D^*G \) | Number of Types |
|------------------|---------------------------------|----------------|
| \( D^{3\omega_3}((Z_2)^3) \), \( D(D_4) \) | 7 |
| \( D^{3\omega_3}((Z_2)^3) \), \( D^7(Q_8) \) | 7 |
| \( D^{3\omega_3}((Z_2)^3) \), \( D(Q_8) \), \( D^{3\omega_3}((D_4) \), \( D^{3\omega_3}((D_4) \) | 28 |
| \( D^{3\omega_3}((Z_2)^3) \), \( D^{3\omega_3}((D_4) \) | 21 |
| \( D^{3\omega_3}((Z_2)^3) \) | 1 |

TABLE VI. \( D^*(G) \), the twisted quantum double model of \( G \) in 2+1D, and their 3-cocycles \( \omega_3 \) (involving Type III) types in \( C_{(Z_2)^3}^{2D} \). We classify the 64 types of 2D non-Abelian twisted gauge theories to 5 classes, which agree with Ref.64. Each class has distinct non-Abelian statistics. Both dihedral group \( D_4 \) and quaternion group \( Q_8 \) are non-Abelian groups of order 8, as \( |D_4| = |Q_8| = |(Z_2)^3| = 8 \). \( D^*G \) data can be found in Ref.64. Details are reserved to Appendix A.

From Table VI, we show that two classes of 3-cocycles for \( D^{3\omega_3}((Z_2)^3) \) of 2D can have dual descriptions by gauge theory of non-Abelian dihedral group \( D_4 \), quaternion group \( Q_8 \). However, the other three classes of 3-cocycles for \( D^{3\omega_3}((Z_2)^3) \) do not have a dual (untwisted) non-Abelian gauge theory.

Now let us go back to consider 3D \( C_{(Z_2)^4,IV}^{2D} \), with \( |Z_2|^4 = 16 \). From Ref.39, we know 3+1D \( D_4 \) gauge theory has decomposition by its 5 centralizers. Apply the rule of decomposition to other groups, it implies that for untwisted group \( G \) in 3D \( C_{G}^{2D} \), we can decompose it into sectors of \( C_{G_0}^{2D} \), here \( G_0 \) becomes the centralizer of the conjugacy class(model) b: \( C_{G}^{2D} = \oplus b C_{G_0}^{2D} \). Some useful information is:

\[
\begin{align*}
C_{(Z_2)^4}^{1D} &= 16 C_{(Z_2)^4}^{2D} \\
C_{D_4}^{2D} &= 2C_{D_4}^{2D} \oplus C_{D_4}^{2D} \oplus C_{Z_2}^{2D} \\
C_{Z_2 \times D_4}^{2D} &= 4C_{Z_2 \times D_4}^{2D} \oplus 4C_{Z_2 \times D_4}^{2D} \oplus 2C_{Z_2 \times Z_4}^{2D} \\
C_{Q_8}^{2D} &= 2C_{Q_8}^{2D} \oplus 3C_{Z_2}^{2D} \\
C_{Z_2 \times Q_8}^{2D} &= 4C_{Z_2 \times Q_8}^{2D} \oplus 6C_{Z_2 \times Z_4}^{2D}.
\end{align*}
\]
and we find that no such decomposition is possible from |G| = 16 group to match Eq. (54)’s. Furthermore, if there exists a non-Abelian G_{n,Abel} to have Eq. (54), those (Z_2)^4, (Z_2) × (D_4) or the twisted (Z_2)^4 must be the centralizers of G_{n,Abel}. But one of the centralizers (the centralizer of the identity element as a conjugacy class b = 0) of G_{n,Abel} must be G_{n,Abel} itself, which has already ruled out from Eq. (55), (57). Thus, we prove that C_{3D}^{2D}(Z_2)^4,ω_{4,IV} is not a normal 3+1D gauge theory (not Z_2 × D_4, neither Abelian nor non-Abelian) but must only be a twisted gauge theory.

We can see the physics from Eq.(54), the three-string statistics under the 0^2_1 flux sector as the branch cut. Nothing prevents us from considering more generic knot and link patterns for three-string or multi-string braiding. Our reason is here - From the full modular SL(3, Z) group viewpoint, the S^{xyz} is a necessary generator to access the full data of the SL(3, Z) group.

FIG. 13. For 3+1D Type IV ω_{4,IV} twisted gauge theory C_{3D}^{2D}(ω_{4,IV},ω_{4,IV}): (a) Two-string statistics in unlink 0^2_1 configuration is Abelian. (The b = 0 sector as C_{2D}^b.) (b) Three-string statistics in two Hopf links 2^1_1 # 2^1_2 configuration is non-Abelian. (The b ≠ 0 sector in C_{2D}^b = C_{2D}^{Z_2}ω_{3,III}.) The b ≠ 0 flux sector creates a monodromy effectively acting as the third (black) string threading the (red,blue) strings. We discover that, see Fig.13, for any twisted gauge theory C_{3D}^{2D}(ω_{4,IV},ω_{4,IV}) with Type IV 4-cocycle ω_{4,IV} (which non-Abelian nature is not affected by adding other Type II,III ω_{4,IV}), by threading a third string through two-string unlink 0^2_1 into three-string Hopf links 2^1_1 # 2^1_2 configuration, Abelian two-string statistics is promoted to non-Abelian three-string statistics. We can see the physics from Eq.(54), the C_{2D}^b is Abelian in b = 0 sector; but non-Abelian in b ≠ 0 sector. The physics of Fig.13 is then obvious, by applying our discussion in Sec.III C about the equivalence between string-threading and the b ≠ 0 monodromy causes a branch cut.

(4) Cyclic relation for non-Abelian S^{xyz} in 3D: Interestingly, for the (Z_2)^4 twisted gauge theory with non-Abelian statistics, we find that a similar cyclic relation Eq.(41) still holds as long as two conditions are satisfied: (i) the charge labels are equivalent α = β and (ii) δ_α∈{b,d,dl} · δ_β∈{a,b,ab} · δ_δ∈{d,a,da} = 1. However, Eq.(41) is modified with a factor depending on the dimensionality of Rep α:

$$S^{α,α}_{a,b,d} · S^{α,α}_{b,a,d} · S^{α,α}_{d,a,b} · |\text{dim}(α)|^{-3} = 1.$$

This identity should hold for any Type IV non-Abelian strings. This is a cyclic relation of 3D nature, instead of a dimensional-reducing 2D nature for S^{2D}_{α,c} (b) of Fig.2.

V. CONCLUSION

A. Knot and Link configuration

Throughout our presentation, we have been indicating that the mathematics of knots and links may be helpful to organize our string-braiding patterns in 3D. Here we illustrate them more systematically. We will use Alexander-Briggs notation for the knots and links, see Fig.14.

The knots and links for our string-braiding patterns are organized into Table VII. We recall that, in Sec.III C, the topological spin for a closed string in the b = 0 flux sector of C_{2D}^b does a self-2π flipping under the 0 unknot configuration. Due to our spin-statistics relation of a closed string, we can view the topological spin of b = 0 sector as the exchange statistics of two identical strings in 0^2_1 unlink configuration. On the other hand, for the topological spin in the b ≠ 0 flux sector, we effectively thread a (blue) string through the (black) unknot, which forms a Hopf link 2^1_2. Meanwhile, we can view the topological spin of b ≠ 0 sector as the exchange statistics of two identical strings threaded by a third (black) string in a connected sum of two Hopf links 2^1_1 # 2^1_1 configuration. Furthermore, we can promote two-string Abelian statistics under the 0^2_1 unlink of b = 0 sector to three-string Abelian (in Sec.IV B) or non-Abelian statistics (in Sec.IV C) under Hopf links 2^1_1 # 2^1_2 of b ≠ 0 sector.

FIG. 14. Under Alexander-Briggs notation, an unknot is 0_1, two unknotted can form an unlink 0^2_1. A Hopf link is 2^1_1, a connected sum of two Hopf links is 2^1_1 # 2^1_2.
However, we have learned that our 3D to 2D reduction by Eq.(4) using $SL(2,Z)$ subgroup’s data $S^{xy}$ and $T^{xy}$ already encode all the physics of braidingss under the simplest knots and links in Fig.14 - These include self-flipping topological spin and exchange/braiding statistics (Sec.III C, IV). It suggests that $S^{xy/z}$ contains more than these string-braiding configurations. In addition, there are more generic Mapping Class Groups MCG($M_{space}$) beyond MCG($T^3$) = $SL(3,Z)$, which potentially encode more exotic multi-string braidings.

Indeed, as we already notice in Sec.IV, the 3D $S$ matrix essentially contains the information of three fluxes $(d,a,b) = (d_z,a_y,b_z)$ in Eq.(38), $S^{xy/z} = S_{(a,a,b)(b,c,d)}$. Since strings carry fluxes in 3D, this further suggests that we should look for the braiding involving with three strings, where the 3-loop braiding has also been recently emphasized in Ref.40 and 41.

The configuration we study so far with three strings is the Hopf link $2_1^1 \# 2_1^1$. We propose that using more general three strings pattern, such as the link $N^3_m$ or its connected sum to study topological states. ($N^3_m$ is in Alexander-Briggs notation, here 3 means that there are three closed loops, $N$ means the crossing number, and $m$ is the label for different kinds for $N^3$ linking.) For example, three-string braiding can include links of $6_1^1$, $6_2^3$, $6_3^3$ in Fig.15. Configurations in Fig.15 are potentially promising for studying the braiding statistics of strings to classify or characterize topological orders.

To examine whether the multi-string braiding is topologically well-defined, we propose a way to check that (such as the braiding processes in Fig.13,15):

\[
N^3_m \equiv \text{topological spin (T)} \oplus \text{exchange statistics} \oplus \text{2-string braiding} = (b = 0) \oplus (b \neq 0).
\]

| $C^{2D}$ | Physics of Strings | Knots and Links |
|----------|-------------------|-----------------|
| $b = 0$  | topological spin (T) | $0_1$ |
|          | exchange statistics | $0_1^2$ |
|          | 2-string braiding   | $0_1^2$ |
| $b \neq 0$ | topological spin (T) | $2_1^2$ |
|          | exchange statistics | $2_1^2 \# 2_1^1$ |
|          | 3-string braiding   | $2_1^2 \# 2_1^1$ |

TABLE VII. Various string-braiding patterns in terms of knots and links in Alexander-Briggs notation: the topological spin of a loop, the exchange/braiding statistics of two loops without any background string inserted ($b = 0$ sector) or with another background string inserted ($b \neq 0$ sector). Here we effectively view the string braiding statistics of 3D topological order in terms of 2D sectors: $C^{2D} = \oplus_b C_b^{2D}$.

Before concluding this subsection, another final remark is that in Sec.III C 3, we mention generalizing the framed worldline picture of particles in Fig.9 to the framed worldsheet picture of closed-strings. (ps. The framed worldline is like a worldsheet, the framed worldsheet is like a worldvolume.) Thus, it may be interesting to study how incorporating the framing of particles and strings (with worldline/worldsheet/worldvolume) can provide richer physics and textures into the knot-link pattern.

### B. Cyclic identity for Abelian and non-Abelian strings

In Sec.IV B and Sec.IV C, we discuss cyclic identity for Abelian and non-Abelian strings particularly for 3+1D twisted gauge theories. We find Eq.(60),

\[
\text{"Cyclic identity of 3D’s $S^{xy}$ matrix of Eq.(38) $S^{xy}_{(a,a,b)(b,c,d)} = \frac{1}{|G|} S_{(a,a,b)} \delta_{b,c}$"}:
\]

\[
S_{a,b,d}^{\alpha,\alpha} \cdot S_{d,a,c}^{\alpha,\alpha} \cdot |\text{dim}(\alpha)|^{-3} = 1.
\]

For the Abelian case, the dimension of Rep is simply $\text{dim}(\alpha) = 1$, which reduces to Eq.(41).

On the other hand, we find that there is also another cyclic identity, based on 2D’s $S^{xy}_b = S_{(a,a,b)}^{(a,b)} = \frac{1}{|G|} S^{2D}_{a,a,b} \delta_{b,c}$ matrix of Eq.(34), written in terms of $S^{2D}_{a,a,b}^{(a,b)}$, at least for Abelian strings of Type II, III 4-cocycle twists, namely

\[
\text{"Cyclic identity of 2D’s $S^{xy}$ matrix"}:
\]

\[
S^{2D}_{a,b,c}^{0,0} \cdot S^{2D}_{b,c,a}^{0,0} \cdot S^{2D}_{c,a,b}^{0,0} = 1.
\]
This Eq. (62) cyclic identity has two additional criteria: (1) Here \( \alpha = \beta = 0 \) means that all strings must have zero charges. (2) In addition, the \( \prod_j Z_{N_j} \) flux labels \( a_i, b_j, c_k \) must satisfy that \( a_i = |a| \hat{e}_i, b_j = |b| \hat{e}_j, c_k = |c| \hat{e}_k \) as a multiple of a single unit flux, each only carries one of \( \prod_j Z_{N_j} \) fluxes. Note that \( \hat{e}_j \equiv (0, \ldots, 0, 1, 0, \ldots, 0) \) is defined to be a unit vector with a nonzero component in the \( j \)-th component for the \( Z_{N_j} \) flux. Eq. (62) is true even in the non-canonical basis, such as the case for the \( b \)-flux sector in Table IV. Thus, the fact whether in the canonical basis or not does not affect the identity Eq. (62), at least for the example of Abelian Type II, III 4-cocycles.

This 2D’s \( S_0^{xy} \) cyclic identity in Eq. (62) is indeed the cyclic relation of Ref. 40. From the fact that we associate 2D’s \( S_0^{xy} \) matrix to the dimensional reduction of string braiding in Fig. 2, it shows that the Abelian statistical angle \( \theta_{a_i,c_k,(b_j)} \) can be defined, up to a basis, as

\[
S_{a_i,c_k,(b_j)}^{2D,0,0} = \exp(i \theta_{a_i,c_k,(b_j)}). \tag{63}
\]

Thus Eq. (62) implies a cyclic relation for Abelian statistical angles:

\[
\theta_{a_i,c_k,(b_j)} + \theta_{c_k,b_j,(a_i)} + \theta_{b_j,a_i,(c_k)} = 0 \pmod{2\pi}. \tag{64}
\]

In contrast, the 3D cyclic relation works for both Abelian and non-Abelian strings, and it does not restrict on zero charge but only for equal charges \( \alpha = \beta \). More importantly, Eq. (61) allows any flux for each \( a, b, c \), instead of limiting to a single unit flux or a multiple of a single unit flux in Eq. (62).

C. Main results

We have studied string and particle excitations in 3+1D twisted discrete gauge theories, which belong to a class of topological orders. These 3D theories are gapped topological systems with topology-dependent ground state degeneracy. The twisted gauge theory contains its data of gauge group \( G \) and 4-cocycle twist \( \omega_4 \in H^4(G, \mathbb{F} / \mathbb{Z}) \) of \( G \)’s fourth cohomology group. Such a data provides many types of theories, however several types of theories belong to the same class of a topological order. To better characterize and classify topological orders, we use the mapping class group on \( T^3 \) torus, by \( \text{MCG}(T^3) = \text{SL}(d, \mathbb{Z}) \), to extract the \( \text{SL}(3, \mathbb{Z}) \) modular data \( S_{xyz} \) and \( T_{xyz} \) in the ground state sectors, which however reveal information of gapped excitations of particles and strings. We have posed five main questions Q1-Q5 and other sub-questions throughout our work, and have addressed each of them in some depth. We summarize our results and approaches below, and make comparisons with some recent works:

(1) Dimensional Reduction: By inserting a gauge flux \( b \) into a compactified circle \( z \) of 3D topological order \( C^{3D} \), we can realize \( C^{3D} = \otimes_b C_b^{2D} \), where \( C^{2D} \) becomes a direct sum of degenerate states of 2D topological orders \( C^{2D}_b \) in different flux \( b \) sectors. We should emphasize that this dimensional reduction is not real space decomposition along the \( z \) direction, but the decomposition in the Hilbert space of ground states (excitations basis such as the canonical basis of Eq. (11)). We propose this decomposition in Eq. (5) will work for a generic topological order without a gauge group description. In the most general case, \( b \) becomes certain basis label of Hilbert space. The recent study of Ref. 39 implements the dimensional reduction idea on the normal gauge theories described by 3D Kitaev \( Z_N \) toric code and 3D quantum double models without cocycle twists using the spatial Hamiltonian approach. In our work, we consider more generic twisted gauge theories with a lattice realization in the twisted 3D quantum double models under the framework of Dijkgraaf-Witten theory. 36 We apply both the spatial Hamiltonian approach and the spacetime path integral approach.

(2) Modular Data: We find explicit formula representations of \( SL(3, \mathbb{Z}) \) modular data \( S \) and \( T \) using (i) path integral and cocycle approach, and (ii) Representation (Rep) theory approach. The Rep theory approach is convenient, and perhaps contains more general and simplified expressions. While the recent work either focus on Abelian statistics or focus on normal gauge theories, our formula embodies generic non-Abelian twisted gauge theories thus is most powerful.

(3) Classification and Characterization: We use the modular data \( S \) and \( T \) to characterize the braiding statistics of some 2D and 3D topological orders. We can further use the modular data \( S \) and \( T \) taking into account excitation-relabeling to classify (or partially classify) topological orders. Explicit 2D examples are \( G = (Z_2)^3 \) twisted gauge theories, and 3D examples are \( G = (Z_2)^4 \) twisted gauge theories. Some of our results are compared with the mathematics literature in the Supplemental Material (Appendix A). Some of 2D results are compared to twisted quantum double models \( D^\omega(G) \).

Our result can also facilitate the study of symmetric protected topological states (SPTs) protected by a global symmetry \( G_\ast \). 52 By gauging the \( G_\ast \) symmetry of SPTs, one can use the induced dynamical gauged theory to study the braiding of excitations and to characterize SPTs. 40, 65-67

(4) Physics of string and particle braiding: We provide the physics meaning of the topological spin and spin-statistics relation for a closed string. We also interpret the 3-string braiding statics firstly studied in Ref. 40 from a new perspective - a dimensional reduction with \( b \) flux monodromy. We find that with Type IV 4-cocycle twist for the twisted gauge theory, by threading a third string through two-string unlink \( 0^b_3 \) into three-string Hopf links \( 21^b_2 \) configuration, Abelian two-string statistics is promoted to
non-Abelian three-string statistics. In Ref.39, the sort-of opposite effect of ours is found: where the normal (untwisted) non-Abelian 3D topological order has found with non-Abelian statistics in $b = 0$ sector, but there may have Abelian statistics in $b \neq 0$ sector. Incorporate this understanding, We have a more unified picture organized in Table VIII, for the string-braiding statistics of twisted/untwisted Abelian/non-Abelian gauge theories as topological orders. Since the string deformation on the lattice can blur the Abelian $U(1)$ phase, our non-Abelian string-braiding statistics provides a better alternative for a robust physical observable than Abelian string-braiding statistics.\textsuperscript{40,41} to be tested numerically or experimentally in the future. Last but not least, we propose to use more general patterns, such as $N_m^3$ (or $N_m^3$ # ... ) knots/links of Alexander-Briggs to study the three-string (or multi-string) braiding statistics.

### VI. ACKNOWLEDGEMENTS

JW would like to thank Tian Lan, as well as Ling-Yan Hung and Yidun Wan for helpful conversations and warm encouragements. JW is grateful to Louis H. Kauffman for a long blackboard discussion about the theory of knots and links at Perimeter Institute, along with Yidun Wan. JW also thanks M. de Wild Propitius for email correspondence in the early 2013 and expressing his interests in our work. JW acknowledges the use of computational resources Compute and Titan at Perimeter Institute. We thank Zheng-Cheng Gu for collaboration on a related work Ref.69.

During the Symmetry in Topological Phases workshop at Princeton University, we become aware that the authors of Ref.40 are working on the braiding statistics of 3+1D gapped phases, which intersect some of our studies, but also further inspire our work. In the long process of preparing this manuscript, we notice two recent works appear in Ref.40 and 41 dealing with the Abelian braiding statistics of twisted gauge theories. Also a recent preprint\textsuperscript{58} considers the surface topological order of SPTs with loop braiding statistics.

This research is supported by NSF Grant No. DMR-1005541, NSFC 11074140, NSFC 11274192, BMO Financial Group and the John Templeton Foundation. JW has been supported in part by the U.S. Department of Energy under cooperative research agreement Contract Number DE-FG02-05ER41360, and by Isaac Newton Chair Fellowship. Research at Perimeter Institute is supported by the Government of Canada through Industry Canada and by the Province of Ontario through the Ministry of Research, Economic Development & Innovation.

### Supplemental Material

#### Appendix A: Group Cohomology and Cocycles

##### 1. Cohomology group

Here we review the cohomology group $\mathcal{H}^d + 1(G, \mathbb{R}/\mathbb{Z}) = \mathcal{H}^d + 1(G, U(1))$ by $\mathbb{R}/\mathbb{Z} = U(1)$, as the $(d + 1)$th-cohomology group of $G$ over $G$ module $U(1)$. Each class in $\mathcal{H}^d + 1(G, \mathbb{R}/\mathbb{Z})$ corresponds to a distinct $(d + 1)$-cocycles. The $n$-cocycle is a $n$-cochain additionally satisfying the $n$-cochain-conditions $\delta \omega = 1$. The $n$-cochain is a mapping $\omega(A_1, A_2, \ldots, A_n) : G^n \rightarrow U(1)$ (which inputs $A_i \in G$, $i = 1, \ldots, n$, and outputs a $U(1)$ phase). The $n$-cochains satisfy the group multiplication rule:

\[
(\omega_1 \cdot \omega_2)(A_1, \ldots, A_n) = \omega_1(A_1, \ldots, A_n) \cdot \omega_2(A_1, \ldots, A_n),
\]

(A1)
thus form a group. The coboundary operator $\delta$

$$\delta c(g_1, g_2, \ldots, g_{n+1}) \equiv c(g_2, \ldots, g_{n+1})c(g_1, \ldots, g_n)(-1)^{n+1} \prod_{j=1}^{n} c(g_1, \ldots, g_j g_{j+1}, \ldots, g_{n+1})(-1)^j,$$

(A2)

defines the n-cocycle-condition $\delta \omega = 1$ (a pentagon relation in 2D). We check the distinct n-cocycles are not equivalent by n-coboundaries. The n-cochain forms a group $C^n$, the n-cocycle forms a subgroup $Z^n$ of $C^n$, and the n-coboundary further forms a subgroup $B^n$ of $Z^n$ (since $\delta^2 = 1$). Overall, it shows $B^n \subset Z^n \subset C^n$. The n-cohomology group is exactly a relation of a kernel $Z^n$ (the group of n-cocycles) modding out an image $B^n$ (the group of n-coboundaries):

$$H^n(G, U(1)) = Z^n/B^n.$$  

(A3)

To derive the expression of $H^d(G, U(1))$ in terms of groups explicitly, we apply some key formulas:

(1). Künneth formula:

We denote $R$ as a ring, $\mathbb{M}, \mathbb{M}'$ as the R-modules, $X, X'$ are some chain complex. The Künneth formula shows the cohomology of a chain complex $X \times X'$ in terms of the cohomology of a chain complex $X$ and another chain complex $X'$. For topological cohomology $H^d$, we have

$$H^d(X \times X', \mathbb{M} \otimes_R \mathbb{M}') \cong \bigoplus_{k=0}^d H^k(X, \mathbb{M}) \otimes_R H^{d-k}(X', \mathbb{M}').$$  

(A4)

$$H^d(X \times X', \mathbb{M}) \cong \bigoplus_{k=0}^d H^k(X, \mathbb{M}) \otimes_R H^{d-k}(X', \mathbb{Z}) \oplus \bigoplus_{k=0}^{d+1} \text{Tor}_1^R(H^k(X, \mathbb{M}), H^{d-k+1}(X', \mathbb{Z})).$$  

(A5)

The above is valid for both topological cohomology $H^d$ and group cohomology $H^d$ (for $G'$ is a finite group):

$$H^d(G \times G', \mathbb{M}) \cong \bigoplus_{k=0}^d H^k(G, \mathbb{M}) \otimes_R H^{d-k}(G', \mathbb{Z}) \oplus \bigoplus_{k=0}^{d+1} \text{Tor}_1^R(H^k(G, \mathbb{M}), H^{d-k+1}(G', \mathbb{Z})).$$  

(A6)

(2). Universal coefficient theorem (UCT) can be derived from Künneth formula, Eq. (A5), by taking $X = 0$ or $Z_1$ or a point thus only $H^0(X', \mathbb{M}) = \mathbb{M}$ survives,

$$H^d(X', \mathbb{M}) \cong \mathbb{M} \otimes_R H^d(X', \mathbb{Z}) \oplus \text{Tor}_1^R(\mathbb{M}, H^{d+1}(X', \mathbb{Z})).$$  

(A7)

Using UCT, we can rewrite Eq. (A5) as a decomposition below.

(3). Decomposition:

$$H^d(X \times X', \mathbb{M}) \cong \bigoplus_{k=0}^d H^k[X, H^{d-k}(X', \mathbb{M})].$$  

(A8)

The above is valid for both topological cohomology and group cohomology:

$$H^d(G \times G', \mathbb{M}) \cong \bigoplus_{k=0}^d H^k[G, H^{d-k}(G', \mathbb{M})],$$  

(A9)

provided that both $G$ and $G'$ are finite groups.

The expression of Künneth formula is in terms of the tensor-product operation $\otimes_R$ and the torsion-product $\otimes_R$ operation of a base ring $R$, which we write $\otimes_R \equiv \otimes_1^R$ as shorthand, their properties are:

$$\mathbb{M} \otimes_Z \mathbb{M}' \cong \mathbb{M}' \otimes_Z \mathbb{M},$$

$$\mathbb{Z} \otimes_Z \mathbb{M} \cong \mathbb{M} \otimes_Z \mathbb{Z} = \mathbb{M},$$

$$\mathbb{Z}_n \otimes_Z \mathbb{M} \cong \mathbb{M} \otimes_Z \mathbb{Z}_n = \mathbb{M}/n\mathbb{M},$$

$$\mathbb{Z}_n \otimes_Z U(1) \cong U(1) \otimes \mathbb{Z}_n = 0,$$

$$\mathbb{Z}_m \otimes_Z \mathbb{Z}_n = \mathbb{Z}_{\gcd(m,n)},$$

$$(\mathbb{M}' \otimes \mathbb{M}'') \otimes_R \mathbb{M} = (\mathbb{M}' \otimes \mathbb{R}_1 \mathbb{M}) \oplus (\mathbb{M}'' \otimes \mathbb{R}_1 \mathbb{M}),$$

$$\mathbb{M} \otimes_R (\mathbb{M}' \otimes \mathbb{M}'') = (\mathbb{M} \otimes_R \mathbb{M}') \oplus (\mathbb{M} \otimes_R \mathbb{M}'');$$  

(A10)

and

$$\text{Tor}_1^R(\mathbb{M}, \mathbb{M}') \equiv \mathbb{M} \otimes_R \mathbb{M}',$$

$$\mathbb{M} \otimes_R \mathbb{M}' \cong \mathbb{M} \otimes_R \mathbb{M},$$

$$\mathbb{Z} \otimes_Z \mathbb{M} = \mathbb{M} \otimes_Z \mathbb{Z} = 0,$$

$$\mathbb{Z}_n \otimes Z \mathbb{M} = \{m \in \mathbb{M} | nm = 0\},$$

$$\mathbb{Z}_n \otimes Z U(1) = \mathbb{Z}_n,$$

$$\mathbb{Z}_m \otimes Z \mathbb{Z}_n = \mathbb{Z}_{(m,n)},$$

$$\text{Tor}_1^R(U(1), U(1)) = 0,$$

$$\mathbb{M}' \otimes \mathbb{M}'' \otimes_R \mathbb{M} = \mathbb{M}' \otimes_R \mathbb{M} \oplus \mathbb{M}'' \otimes_R \mathbb{M},$$

$$\mathbb{M} \otimes_R \mathbb{M}' \otimes \mathbb{M}'' = \mathbb{M} \otimes_R \mathbb{M}' \otimes \mathbb{M} \otimes_R \mathbb{M}.$$  

(A11)

For other details, we suggest to read Ref.52 and Reference therein.

We summarize some useful facts in Table IX, and some derived results in Table X.

TABLE X. The table shows the exponent of the $\mathcal{H}_{\text{gcd}}^d(N(i))$ class in $\mathcal{H}^d(G, U(1))$ for $G = \prod_{i=1}^n Z_{N_i}$. We define a shorthand of $\mathcal{H}_{\text{gcd}}(N_{ij}) \equiv \mathcal{H}_{\text{gcd}}(N_{ij})$, etc. for lower gcd. Our definition of the Type $m$ is from its number $m$ of cyclic gauge groups in the gcd class $\mathcal{H}_{\text{gcd}}^d(N(i))$. The number of exponents can be systematically obtained by adding all the numbers of the previous column from the top row to a row before the wish-to-determine number. For example, we show that we derive that $\mathcal{H}^0(G, \mathbb{R}/\mathbb{Z}) = \prod_{1 \leq i < j < k \leq m} Z_{N_i} \times Z_{N_{ij}} \times Z_{N_{ijk}}$ and $\mathcal{H}^1(G, \mathbb{R}/\mathbb{Z}) = \prod_{1 \leq i < j < k < m} (Z_{N_i})^3 \times (Z_{N_{ij}})^3 \times Z_{N_{ijk}}$, etc.

2. Derivation of cocycles

To derive Table X, we find that by doing the Künneth formula decomposition carefully for a generic finite Abelian group $G = \prod_i Z_{N_i}$, some corresponding structure becomes transparent. See Table XI.

| $(d+1)\text{dim}$ | $\mathcal{H}^{d+1}(G, U(1))$ | Künneth formula in $\mathcal{H}^{d+1}(G, U(1))$ | path integral forms in “fields” |
|------------------|-------------------------------|---------------------------------|---------------------------------|
| 0+1D             | $Z_{N_1}$                     | $\mathcal{H}^0(Z_{N_1}, U(1))$ | $\exp(ik \int A_1)$           |
| 1+1D             | $Z_{N_{12}}$                  | $\mathcal{H}^1(Z_{N_1}, U(1)) \otimes \mathcal{H}^0(Z_{N_{12}}, U(1))$ | $\exp(ik \int A_1 A_2)$       |
| 2+1D             | $Z_{N_{123}}$                 | $\mathcal{H}^2(Z_{N_1}, U(1)) \otimes \mathcal{H}^1(Z_{N_{12}}, U(1)) \otimes \mathcal{H}^0(Z_{N_{123}}, U(1))$ | $\exp(ik \int A_1 A_2 A_3)$   |
| 3+1D             | $Z_{N_{1234}}$                | $\mathcal{H}^3(Z_{N_1}, U(1)) \otimes \mathcal{H}^2(Z_{N_{12}}, U(1)) \otimes \mathcal{H}^1(Z_{N_{123}}, U(1)) \otimes \mathcal{H}^0(Z_{N_{1234}}, U(1))$ | $\exp(ik \int A_1 A_2 A_3 A_4)$ |

TABLE XI. Some derived facts about the cohomology group and its cocycles.

From the known field theory fact, we know that 2+1D twisted gauge theories from $\mathcal{H}^3(G, U(1)) = \prod_{1 \leq i < j \leq m} Z_{N_i}$ \times $Z_{N_{ij}} \times Z_{N_{ijl}}$, their $Z_{N_i}$ classes are captured by a path integral $\simeq \exp(ik \int A_1 dA_1)$ up to some normalization factor. (Here we omit the wedge product, denoting $A_1 dA_1 \equiv A_1 \wedge d A_1$. We also schematically denote the quantization factor $k_\text{r}$, details of $k_\text{r}$ level quantizations can be found in Ref.69.) The $Z_{N_{ij}}$ classes are captured by a path integral $\simeq \exp(ik \int A_1 dA_1)$, where $A$ is a 1-form gauge field. We deduce that the Künneth formula decomposition in $\mathcal{H}^{d+1}(G, U(1))$ with the torsion product $\text{Tor}_d^G \equiv \mathbb{R}$ suggests a wedge product $\wedge$ structure in the corresponding field theory, while the tensor product $\otimes_Z$ suggests appending an extra exterior derivative $\wedge d$ structure in the corresponding field theory. For example, $\mathcal{H}^1(Z_{N_1}, U(1)) \otimes \mathcal{H}^0(Z_{N_{12}}, U(1)) \to \exp(ik \int A_1 \wedge A_2)$, and $\mathcal{H}^1(Z_{N_1}, U(1)) \to \exp(ik \int A_1)$, then $\mathcal{H}^1(Z_{N_1}, U(1)) \otimes \mathcal{H}^1(Z_{N_{12}}, U(1)) \to \exp(ik \int A_1 A_2)$, etc. Such an organization also shows the corresponding form of cocycles for 3+1D in Table I and 2+1D in Table XII. For example: The relation $A_1 \to a_1$, maps a 1-form field to...
3. Dimensional reduction from a slant product

In general, for dimensional reduction of cochains, we can use the slant product mapping n-cochain $c$ to $(n - 1)$-cochain $i_{g}c$:

$$i_{g}c(g_{1}, g_{2}, \ldots, g_{n-1}) \equiv c(g_{1}, g_{2}, \ldots, g_{j}, g_{j+1} \cdots g_{j'} \cdots g_{n-1})^{n-1} \cdot \prod_{j=1}^{n-1} c(g_{1}, \ldots, g_{j}, g_{j+1} \cdots g_{j'} \cdots g_{n-1})^{-1} \cdot g \cdot (g_{1} \cdots g_{j}) \cdots g_{n-1}^{(-1)^{n-1+j}}. \quad (A12)$$

Here we focus on the Abelian group $G$. For example in 2+1D, we have 3-cocycles from 2-cocycles:

$$C_{A}(B, C) \equiv i_{A}\omega(B, C) = \frac{\omega(A, B, C)\omega(B, C, A)}{\omega(B, A, C)} \quad (A13)$$

In 3+1D, we have 4-cocycles from 3-cocycles:

$$C_{A}(B, C, D) \equiv i_{A}\omega(B, C, D) = \frac{\omega(B, A, C, D)\omega(B, C, D, A)}{\omega(A, B, C, D)\omega(B, C, A, D)} \quad (A14)$$

In order to study the projective representation (the second cohomology group $H^{2}$) from 4-cocycles, we do the slant product again:

$$C_{AB}^{(2)}(C, D) \equiv i_{B}C_{A}(C, D) = \frac{C_{A}(B, C, D)C_{A}(C, D, B)}{C_{A}(C, D, B)} \quad (A15)$$

$$= \frac{\omega(B, A, C, D)\omega(B, C, D, A)}{\omega(A, B, C, D)\omega(B, C, A, D)} \cdot \frac{\omega(A, C, B, D)\omega(C, B, A, D)}{\omega(C, A, B, D)\omega(C, B, A, D)} \cdot \frac{\omega(C, A, D, B)\omega(C, D, B, A)}{\omega(C, A, D, B)\omega(C, D, B, A)} \quad (A16)$$

4. 2+1D topological orders of $H^{3}(G, R/\mathbb{Z})$

a. 3-cocycles

Here we organize the known fact about the third cohomology group $H^{3}(G, R/\mathbb{Z})$ with $G = \prod_{i=1}^{k} Z_{N_{i}}$:

$$H^{3}(G, R/\mathbb{Z}) = \bigoplus_{1 \leq i < j \leq k} Z_{N_{i}} \times Z_{N_{ij}} \times Z_{N_{ij}}.$$  

| $H^{3}(G, R/\mathbb{Z})$ | 3-cocycle name | 3-cocycle form | Induced $C_{a}(b, c)$ |
|--------------------------|----------------|----------------|---------------------|
| $Z_{N_{i}}$              | Type I $k_{(i)}$ | $\omega_{(i)}^{(1)}(a, b, c) = \exp \left( \frac{2\pi i k}{N_{i}} a_{i}(b_{i} + c_{i} - b_{i} + c_{i}) \right)$ | $\exp \left( \frac{2\pi i k}{N_{i}} a_{i}(b_{i} + c_{i} - b_{i} + c_{i}) \right)$ |
| $Z_{N_{j}}$              | Type II $k_{(j)}$ | $\omega_{(j)}^{(2)}(a, b, c) = \exp \left( \frac{2\pi i k}{N_{j}} a_{j}(b_{j} + c_{j} - b_{j} + c_{j}) \right)$ | $\exp \left( \frac{2\pi i k}{N_{j}} a_{j}(b_{j} + c_{j} - b_{j} + c_{j}) \right)$ |
| $Z_{N_{ij}}$             | Type III $k_{(ij)}$ | $\omega_{(ij)}^{(3)}(a, b, c) = \exp \left( \frac{2\pi i k}{N_{ij}} a_{b}c_{j} \right)$ | $\exp \left( \frac{2\pi i k}{N_{ij}} (a_{b}c_{j} - a_{b}c_{j} + b_{i}c_{i}a_{j}) \right)$ |

TABLE XII. The cohomology group $H^{3}(G, R/\mathbb{Z})$ and 3-cocycles $\omega_{3}$ for a generic finite Abelian group $G = \prod_{i=1}^{k} Z_{N_{i}}$. The first column shows the classes in $H^{3}(G, R/\mathbb{Z})$. The second column shows the topological term indices for 2+1D twisted gauge theory. (When all indices $k...k = 0$, it becomes the normal untwisted gauge theory.) The third column shows explicit 3-cocycle function $\omega_{3}(a, b, c)$: $(G)^{3} \rightarrow U(1)$. Here $a = (a_{1}, a_{2}, \ldots, a_{k})$, with $a \in G$ and $a_{i} \in Z_{N_{i}}$. Same notations for $b, c, d$. The last column shows induced 2-cocycles from the slant product $C_{a}(b, c)$ using Eq.(A13).

We will study the the 2D's MCG($\mathbb{T}^{2}$) = $SL(2, \mathbb{Z})$ modular data: $S, T$ using Rep theory approach.
b. Projective Rep and $S$, $T$ for Abelian topological orders

This section will simply review some known facts for the later convenience of new results. Much of the discussions can be absorbed from Ref.\textsuperscript{42, 50, 51, and 63}. Firstly we study the Abelian topological orders from Type I, II 3-cocycles $\omega_3$ of Table XII for 2+1D topological orders. We can determine the $C_a$ projective representation (Rep) and $\tilde{\rho}_a^h(b)$:

$$\tilde{\rho}_a^h(b)\tilde{\rho}_a^c(c) = C_a(b, c)\tilde{\rho}_a^{bc}(bc).$$  \hfill (A17)

Given $Z_a$ is the centralizer of $a \in G$, $C_a$ determines the projective Rep of $Z_a$. Each $C_a$ classifies a class of projective Rep named $C_a$-representations $\tilde{\rho} : Z_a \to \text{GL}(Z_a)$. In Type I, II $\omega_3$, the irreducible $C_A$-representations $\tilde{\rho}_a$ of $Z_a$ are in the one-to-one correspondence to the irreducible linear representations. The linear Rep originates from the normal untwisted $\prod_i Z_{N_i}$ gauge theory/toric code is: $\text{exp}(2\pi i (\sum_i \frac{1}{N_i} \alpha_i h_i))$. It has pure-charge ($\alpha_i$)-pure-flux ($h_i$) coupling formulated by a BF theory in any dimension (a mutual Chern-Simons theory in 2+1D). The full $C_a$-representations is:

$$\tilde{\rho}_a^h(h) = \exp \left(2\pi i \left( \sum_i \frac{1}{N_i} \alpha_i h_i \right) \right) \exp \left(2\pi i \left( \sum_i \frac{1}{N_i} p_i g_i h_i \right) \right) \exp \left(2\pi i \sum_{i,j} \frac{1}{N_i N_j} p_{ij} (a_i a_j) \right).$$ \hfill (A18)

We will interpret $\langle \alpha_1, g_1, \alpha_2, g_2, \alpha_3, g_3 \rangle$ and $\langle \beta_1, h_1, \beta_2, h_2, \beta_3, h_3 \rangle$ as the charges $\alpha, \beta$ and fluxes $a, b$ of particles in a doubled basis $|\alpha, g \rangle, |\beta, h \rangle$. The generic $T$ matrix formula of modular SL(2, $Z$) data is\textsuperscript{42,50}

$$T_{(\alpha, A)(\beta, B)} = T_{(\alpha, A)} \delta_{\alpha, \beta} \delta_{A, B} = \frac{\text{Tr} \tilde{\rho}_a^h(g^A)}{\text{dim}(\alpha)}. \hfill (A19)$$

We obtain:

$$T_{(\alpha, A)} = \exp \left(2\pi i \left( \sum_i \frac{1}{N_i} \alpha_i a_i \right) + \sum_{j=1,2,3} \frac{1}{N_j} p_j (a_j^2) + \sum_{i,j=12,13} \frac{1}{N_i N_j} p_{ij} (a_i a_j) \right), \hfill (A20)$$

which $T_{(\alpha, A)} = e^{i\omega_3}$ describe the exchange statistics of two identical particles or the topological spin of the same particle. On the other hand, the generic $S$ matrix formula in 2+1D reads from\textsuperscript{42,50}

$$S_{(\alpha, A)(\beta, B)} = \frac{1}{|G|} \sum_{gh=h^g} \text{Tr} \tilde{\rho}_a^h(h)^* \text{Tr} \tilde{\rho}_a^g(g)^* \hfill (A21)$$

yields

$$S_{(\alpha, A)(\beta, B)}(p_j, p_{ij}) = \frac{1}{|G|} \exp \left( -2\pi i \sum_i \frac{1}{N_i} \alpha_i b_i + \beta_i a_i + \sum_{j=1,2,3} \frac{1}{N_i} p_j (a_j b_j) + \sum_{i,j=12,13} \frac{1}{N_i N_j} p_{ij} (a_i b_j + b_i a_j) \right). \hfill (A22)$$

One can use a $K$-matrix Chern-Simons theory of an action $S = \frac{1}{4\pi} \int K_{l,l'} a_l \wedge da_l$ to encode the information of $|\alpha, g\rangle, |\beta, h\rangle$ into quasiparticles vectors $l,l'$ respectively, and formulate a $K$ with $S_{l,l'}(p_j, p_{ij}) = \frac{1}{|G|} \exp(-2\pi i l^T K^{-1} l')$. We can use $S$, $T$ to study the classifications of classes of topological orders. For example, for $G = (Z_2)^2$ twisted theories, simply using $T$ under basis(particles)-relabeling, we find the diagonal eigenvalues of $T$ can be labeled by $(N_1, N_{-1}, N_i, N_{-i})$, as numbers of eigenvalues for $T = 1, -1, i, -i$. We show that using the data show in Table XIII is enough to match the classes found in Ref.\textsuperscript{66}. We denote $(n_{\pm 1}, n_{\pm 1}, n_1)$ as the numbers for (the pair of $\pm 1$, the pair of $\pm i$, individual 1). Note that $N_1 + N_{-1} + N_i + N_{-i} = 2n_{\pm 1} + 2n_{\pm i} + n_1 = \text{GSD}^{T_2} = |G|^2$. There are 8 types of 3-cocycles but there are only 4 classes in Table XIII. The number in the bracket $[\cdot]$ of $\omega_3[\cdot]$ indicates the number of $+i$ (or equivalently the number of a pair of $\pm i$, paired due to the twisted quantum doubled model nature).

| Class    | $(N_1, N_{-1}, N_i, N_{-i})$ | $(n_{\pm 1}, n_{\pm 1}, n_1)$ | Number of Types |
|----------|-----------------------------|--------------------------------|-----------------|
| $\omega_3[0]$ | $(10, 6, 0, 0)$           | $(0, 6, 4)$                     | 1               |
| $\omega_3[2]$ | $(8, 4, 2, 2)$            | $(2, 4, 4)$                     | 3               |
| $\omega_3[4]$ | $(6, 2, 4, 4)$            | $(4, 2, 4)$                     | 3               |
| $\omega_3[6]$ | $(4, 4, 0, 6)$            | $(6, 0, 4)$                     | 1               |

TABLE XIII. Phases of $\mathcal{H}^3((Z_2)^2, \mathbb{R}/Z) = (Z_2)^3$. 8 types of 3-cocycles but there are only 4 classes.

For another example, $G = (Z_2)^3$ twisted theories, we find that, in Table XIV, by classifying and identifying the modular $S$, $T$ data, the 64 Abelian types 3-cocycles (all with Abelian statistics) in $\mathcal{H}^3(G, \mathbb{R}/Z)$ are truncated to only 4 classes.
We can denote these two representations as + or \( I, II \) 3-cocycles. There are 8 Abelian charged particles with zero flux, and 14 non-Abelian charged particles (which promote 8 elements in \( \mathbb{R}/\mathbb{Z} \) to \( 8 \) Abelian charges. These charges can be labeled by \((a, \alpha, \beta, \gamma)\). We will label 8 elements in Table XIV. Here we will consider the remaining 64 types 3-cocycles with Type III twist in \( \mathcal{H}^3((Z_2)^3, \mathbb{R}/\mathbb{Z}) \). Although the gauge group \( G \) is Abelian, the Type III cocycle twist promotes the theory to have non-Abelian statistics. Our basic knowledge and formalism are rooted in Ref.42, where the dual \( D_4 \) and \( Q_8 \) gauge theories are found for certain Type III twist. Here we generalize Ref.42's result to all kinds of 3-cocycles twists.

Our expression is the generalized case where 3-cocycles are based on Type III's but can include (or not include) Type I, II 3-cocycles. There are 8 Abelian charged particles with zero flux, and 14 non-Abelian charged particles (which projective Rep \( \rho_\alpha(b) \) is 2 dimensional, described by a rank-2 matrix) with nonzero fluxes as dyons. For \( a, b, c \in G = (Z_2)^3 \), we will label 8 elements in \( G = (Z_2)^3 \) by \((0,0,0), (1,0,0), (0,1,0), (0,0,1), (1,1,0), (1,0,1), (1,1,1)\). We denote the above 8 elements as the abbreviation: \( F(0), F(1), F(2), F(3), F(4), F(5), F(6), F(7) \) accordingly. Let us recall: \( \rho_\alpha(g_b) \) contains \( \alpha \) meaning the representation as charges, also \( g_b \) meaning the flux, and \( g_a \) indicating in general the conjugacy class (i.e. flux) as basis. In short, our notation leads to \( \rho_\alpha(g_b) = \rho_{\text{representation(charge)}}(\text{flux}) \).

- 1 · 8 = 8 particles: \( F(0), (\alpha_1, \alpha_2, \alpha_3) \)

When the flux is zero flux, \( a = F(0) \) is the conjugacy class \( C_{F(0)} \). There are 8 linear irreducible representations as charges. These charges can be labeled by \((\alpha_1, \alpha_2, \alpha_3)\) with \((\alpha_1, \alpha_2, \alpha_3) \in (Z_2)^3, \alpha_1, \alpha_2, \alpha_3 \in \{0,1\}\). So we have

\[
\pi = \frac{2\pi i}{m^2} \left( \sum_{j=1,2,3} \alpha_j b_j \right).
\]

- 7 · 2 = 14 particles: \( F(j), \pm \)

The other remained 7 kinds of fluxes are \( a = F(j) \) for \( j = 1, \ldots, 7 \). There are two kinds of representations for each. We can denote these two representations as + or −. So these together give 14 more type of particles. Totally there are \( 1 \cdot 8 + 7 \cdot 2 = 22 \) quasi-particle excitations as the GSD on \( T^2 \) torus. Generally, the representation is \( \rho_{F(j), \pm}(F(l)) \) for some inserting flux \( F(l) \). This is a 2-dimensional representation. The identity always assigns to \( F(0) \), namely

\[
\rho_{F(j), \pm}(F(0)) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.
\]

We will list down three more elements \( \rho_{F(j), \pm}(F(1)), \rho_{F(j), \pm}(F(2)), \rho_{F(j), \pm}(F(3)) \). The other remaining \( \rho_{F(j), \pm}(F(l)) \) for \( l = 4, \ldots, 7 \) can be determined by Eq.(A17). The representations are adjusted by a 1-dimensional projective Rep by Type I \( \omega_I \), Type II \( \omega_{II} \) 3-cocycles: with topological level quantized coefficients as \( p_1, p_2, p_3 \) of Type I and \( p_{12}, p_{13}, p_{23} \) of Type II. Under the Type I, Type II twists, the Type III Rep adjusts to:

\[
\rho_{F(j), \pm}^{F(0)}(F(l)) = \rho_{F(j), \pm}^{F(0) = a}(b) \rightarrow \rho_{F(j), \pm}^{F(0)}(b) e^{i \frac{\pi}{4} \sum_{j,i \in \{1,2,3\}} p_{j} a_{j} b_{i} + p_{a} a_{i} b_{j}}.
\]

- 2 particles: \( F(1), \pm \)

\( j = 1 \), here \((\alpha_1, \alpha_2, \alpha_3) = F(1) = (1,0,0)\),

\[
\rho_{F(j), \pm}(F(1)) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} e^{i \pi(\alpha_1)} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi(\alpha_2 + \alpha_1)}, \rho_{F(j), \pm}(F(2)) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi(\alpha_2 + \alpha_1 + \alpha_3)}, \rho_{F(j), \pm}(F(3)) = \begin{pmatrix} 0 & 1 \\ 0 & 1 \end{pmatrix} e^{i \pi(\alpha_3 + \alpha_1 + \alpha_2 + \alpha_3)}.
\]

- 2 particles: \( F(2), \pm \)

\( j = 2 \), here \((\alpha_1, \alpha_2, \alpha_3) = F(2) = (0,1,0)\),

\[
\rho_{F(j), \pm}(F(1)) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} e^{i \pi(\alpha_1)} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi(\alpha_2 + \alpha_1)}, \rho_{F(j), \pm}(F(2)) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi(\alpha_2 + \alpha_1 + \alpha_3)}, \rho_{F(j), \pm}(F(3)) = \begin{pmatrix} 0 & 1 \\ 0 & 1 \end{pmatrix} e^{i \pi(\alpha_3 + \alpha_1 + \alpha_2 + \alpha_3)}.
\]
• 2 particles: $F(3), \pm$
  $j = 3$, here $(a_1, a_2, a_3) = F(3) = (0, 0, 1)$,

\[
\begin{align*}
\rho_{F(3), \pm}^F(F(1)) &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_1 a_1)}, \\
\rho_{F(3), \pm}^F(F(2)) &= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} e^{i \pi (p_2 a_2 + p_1 a_1)}, \\
\rho_{F(3), \pm}^F(F(3)) &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} e^{i \pi (p_3 a_3 + p_1 a_1 + p_2 a_2)}
\end{align*}
\]

• 2 particles: $F(4), \pm$
  $j = 4$, here $(a_1, a_2, a_3) = F(4) = (1, 1, 0)$,

\[
\begin{align*}
\rho_{F(4), \pm}^F(F(1)) &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_1 a_1)}, \\
\rho_{F(4), \pm}^F(F(2)) &= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} e^{i \pi (p_2 a_2 + p_1 a_1)}, \\
\rho_{F(4), \pm}^F(F(3)) &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} e^{i \pi (p_3 a_3 + p_1 a_1 + p_2 a_2)}
\end{align*}
\]

• 2 particles: $F(5), \pm$
  $j = 5$, here $(a_1, a_2, a_3) = F(5) = (1, 0, 1)$,

\[
\begin{align*}
\rho_{F(5), \pm}^F(F(1)) &= \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_1 a_1)}, \\
\rho_{F(5), \pm}^F(F(2)) &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_2 a_2 + p_1 a_1)}, \\
\rho_{F(5), \pm}^F(F(3)) &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_3 a_3 + p_1 a_1 + p_2 a_2)}
\end{align*}
\]

• 2 particles: $F(6), \pm$
  $j = 6$, here $(a_1, a_2, a_3) = F(6) = (0, 1, 1)$,

\[
\begin{align*}
\rho_{F(6), \pm}^F(F(1)) &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_1 a_1)}, \\
\rho_{F(6), \pm}^F(F(2)) &= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} e^{i \pi (p_2 a_2 + p_1 a_1)}, \\
\rho_{F(6), \pm}^F(F(3)) &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} e^{i \pi (p_3 a_3 + p_1 a_1 + p_2 a_2)}
\end{align*}
\]

• 2 particles: $F(7), \pm$
  $j = 7$, here $(a_1, a_2, a_3) = F(7) = (1, 1, 1)$, (note in particular this Rep, our choice $\mp$ differs from Ref.42.)

\[
\begin{align*}
\rho_{F(7), \pm}^F(F(1)) &= \mp \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_1 a_1)}, \\
\rho_{F(7), \pm}^F(F(2)) &= \pm \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} e^{i \pi (p_2 a_2 + p_1 a_1)}, \\
\rho_{F(7), \pm}^F(F(3)) &= \pm \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} e^{i \pi (p_3 a_3 + p_1 a_1 + p_2 a_2)}
\end{align*}
\]

With the above projective Rep $\tilde{\rho}_{a}^{(b)}$, we can derive the analytic form of modular data $S$, $T$ in 2D. Here for $G = (Z_2)^3$,

\[
T_{a}^{A} = e^{\frac{i \pi (\sum_{i,m \in \{1,2,3,4\} \text{ s.t. } i < m} p_{i} a_{i}^{2} + \text{other terms})}{2}} (\pm)_{a} (i) \eta_{a,a} \rightarrow T_{a}^{A} = \pm 1 \text{ or } \pm i \quad (A25)
\]

\[
\eta_{g_1, g_2} = \begin{cases} 0, & \text{if } C_{g_1}(g_2, g_2) = +1, \\
1, & \text{if } C_{g_1}(g_2, g_2) = -1. \end{cases} \quad (A26)
\]

More explicitly, we compute $T_{a}^{A}$ in Table A.4.c:

| particle | $T_{a}^{A}$ |
|----------|-------------|
| $(1, a_1, a_2, a_3, F(0))$ | 1 |
| $(\pm, F(1)), (\pm, F(2)), (\pm, F(3))$ | $\pm i^p_1, \pm i^p_2, \pm i^p_3$ |
| $(\pm, F(4)), (\pm, F(5)), (\pm, F(6))$ | $\pm i^p_1 + p_2^p + i^p_2 + p_3^p, \pm i^p_1 + p_2^p + p_3^p, \pm i^p_1 + p_2^p + p_3^p$ |
| $(\pm, F(7))$ | $\pm i^p_1 + p_2^p + p_3^p + i^p_2 + p_3^p + i^p_3$ |

Table XV. The modular $T_{a}^{A}$ matrix for 2D twisted $(Z_2)^3$ theories with non-Abelian statistics. The table contains all 64 non-Abelian theories in $H^A((Z_2)^3, \mathbb{R}/\mathbb{Z})$.

With the modular $S^{xy} = S^{xy}_{(a,a),(b,b)}$ matrix (of 64 types of 2D twisted $(Z_2)^3$ theories with non-Abelian statistics):

\[
S = \frac{1}{|G|} \begin{pmatrix}
1 & 2(-1)^{b_1 a_1 + b_2 a_2 + b_3 a_3} & 2(-1)^{b_1 a_1 + b_2 a_2 + b_3 a_3} \\
2(-1)^{a_1 b_1 + a_2 b_2 + a_3 b_3} & \delta_{a,b} A_{4} (\pm 1)^{\eta_{a,a}}, (\pm 1) & \delta_{a,b} A_{4} (\pm 1)^{\eta_{a,a}}, (\pm 1) \\
2(-1)^{a_1 b_1 + a_2 b_2 + a_3 b_3} & -\delta_{a,b} A_{4} (\pm 1)^{\eta_{a,a}}, (\pm 1) & \delta_{a,b} A_{4} (\pm 1)^{\eta_{a,a}}, (\pm 1) \\
\end{pmatrix}
\]

In Eq.(A27), the factor $(\pm 1)^{\eta_{a,a}}$ is derived from a computation of $(i)^{\eta_{a,a}}, (i)^{\eta_{a,a}} = \delta_{a,b}$. From Eq.(A26), we notice that $\eta_{a,a} = 1$ is nonzero only when $a = (1, 1, 1) = F(7)$ for the $(Z_2)^3$ flux.
5. Classification of 2+1D twisted \((Z_2)^3\) gauge theories, \(D^\omega((Z_2)^3)\) and \(\mathcal{H}^3((Z_2)^3, \mathbb{R}/\mathbb{Z})\).

Those twisted \((Z_2)^3\) gauge theories dual to \(D_4\), \(Q_8\) non-Abelian gauge theories are firstly discovered by Ref.42. Here we will present the other three classes which cannot be dual to any non-Abelian gauge theory, but only to a twisted (Abelian or non-Abelian) gauge theory itself. We again label the diagonal eigenvalues of \(T\) by \((N_1, N_{-1}, N_i, N_{-i})\), their number of eigenvalues for \(T = 1, -1, i, -i\). We also use shorthand \((n_{\pm 1}, n_{\pm i}, n_1)\) instead, which stands for the numbers for (the pair of \(\pm i\), the pair of \(\pm 1\), individual 1) in the diagonal of \(T\). Note that \(N_1 + N_{-1} + N_i + N_{-i} = 2n_{\pm 1} + 2n_{\pm i} + n_1 = \text{GSD}_{12} = 22\). There are 64 types of 3-cocycles corresponding to theories with non-Abelian statistics but there are only 5 inequivalent classes in Table XIII. The number in the bracket \([\_]\) of \(\omega_3[\_]\) indicating the number of +i (or equivalently the number of a pair of ±i, paired due to the quantum doubled model nature).

| Class   | \([n_{\pm 1}, n_{\pm i}, n_1]\) | \([N_1, N_{-1}, N_i, N_{-i}]\) | Twisted quantum double \(D^\omega(G)\) | Number of Types |
|---------|----------------------------------|----------------------------------|----------------------------------------|----------------|
| \(\omega_3[1]\) | (1.6.8) | (14.6.1.1) | \(D^{3\alpha}[\mathbb{Z}_2^3], D(D_4)\) | 7 |
| \(\omega_3[3d]\) | (3.4.8) | (12.4.3.3) | \(D^{3\alpha}[\mathbb{Z}_2^3], D(Q_8)\) | 7 |
| \(\omega_3[3i]\) | (3.4.8) | (12.4.3.3) | \(D^{3\alpha}[\mathbb{Z}_2^3], D(Q_8), D(Q_4), D^{\alpha^2}(D_4)\) | 28 |
| \(\omega_3[5]\) | (5.2.8) | (10.2.5.5) | \(D^{3\alpha}[\mathbb{Z}_2^3], D^{\alpha^2}(D_4)\) | 21 |
| \(\omega_3[7]\) | (7.0.8) | (8.0.7.7) | \(D^{3\alpha}[\mathbb{Z}_2^3]\) | 1 |

TABLE XVI. \(D^\omega(G)\) is the twisted quantum double of \(G\) with a cocycle twist \(\omega\) of \(G\)'s cohomology group. Here we consider a 3-cocycle twist \(\omega_3\) in \(\mathcal{H}^3((Z_2)^3, \mathbb{R}/\mathbb{Z}) = (Z_2)^7\), which \(\omega_3\) contains a factor of Type III 3-cocycle. We compute the second and the fourth columns, and then compare them with the mathematics literature Ref.64 to match for the third column. We find that the 64 types of non-Abelian theories are truncated to 5 classes.

Although \(\omega_3[3d]\) and \(\omega_3[3i]\) share the same \(T\) matrix data, but they can still be distinguished by the linear dependency of the fluxes which carry three pairs of eigenvalues 1. (And, of course, they can be distinguished by the more-involved \(S\) matrix.) There are 7 types in the \(\omega_3[3d]\) class, whose \(\pm i\) are generated by linear-dependent fluxes. Another 28 types in the \(\omega_3[3i]\) class, whose \(\pm i\) are generated by linear-independent fluxes. In this notation of linear (in)dependency, we have \(\omega_3[1] = \omega_3[\bar{1}], \omega_3[5] = \omega_3[\bar{5}], \omega_3[7] = \omega_3[\bar{7}]\). Such a concept is also used in the mathematic literature in Ref.64, where they study the Frobenius-Schur indicators, Frobenius-Schur exponents and the support of cocycle twist, supp \(\omega\); and use these data to classify twisted quantum double model \(D^\omega(G)\). Remarkably, we find that using our data is enough to match the classes found in the math literature\(^{64}\) in the quantum double and module category framework.

These altogether with Sec.A 4 b form a complete data set of \(\mathcal{H}^3((Z_2)^3, \mathbb{R}/\mathbb{Z}) = (Z_2)^7\), where 128 types of 3-cocycles fall into 4 distinct classes of Abelian topological orders in Table XIII and 5 distinct classes of non-Abelian topological orders in Table XVI. Totally there are 9 distinct classes of topological orders within twisted \((Z_2)^3\) gauge theories. We note that \(\omega_3[3i], \omega_3[5], \omega_3[7]\) can only be twisted gauge theories, not dual to any untwisted non-Abelian gauge theory.

6. 3+1D topological orders of \(\mathcal{H}^4(G, \mathbb{R}/\mathbb{Z})\)

This section continues the discussion and notations from \(\mathcal{H}^3(G, \mathbb{R}/\mathbb{Z})\) of 2+1D to \(\mathcal{H}^4(G, \mathbb{R}/\mathbb{Z})\) of 3+1D topological orders. Now we fill in some more information about the data of the projective Rep.

a. Projective Rep and \(S\), \(T\) for Abelian topological orders

The data of \(\mathcal{P}^4_{\alpha}(c)\) is organized below for \(G = Z_{N_1} \times Z_{N_3} \times Z_{N_5}\) of the cohomology group \(\mathcal{H}^4(G, \mathbb{R}/\mathbb{Z})\). Its modular \(S\), \(T\) matrices for this Rep have been presented in Table II, III, IV. In the main text, we provide an example of classifying 3D topological orders from 3+1D \((Z_2)^2\) twisted gauge theories of 4 types (from \(\mathcal{H}^4((Z_2)^3, \mathbb{R}/\mathbb{Z}) = (Z_2)^7\)), and find out that 4 types are truncated to only 2 distinct classes of topological orders.

b. Projective Rep and \(S\), \(T\) for non-Abelian topological orders

Below we will present the data of twisted gauge theories for those with non-Abelian statistics in \(\mathcal{H}^4(G = (Z_2)^4, \mathbb{R}/\mathbb{Z})\) labeled by 4-cocycles \(\omega_4\). Among \(\mathcal{H}^4((Z_2)^4, \mathbb{R}/\mathbb{Z}) = (Z_2)^{21}\) types of theories, there are 20 types of them endorsed
with non-Abelian statistics. In some case, we will write the formula in terms of a slightly generic matrix.

Analogous to Sec.A.4.c, we recall that the 3D triple basis renders: \( \tilde{\rho}_\alpha^{-a,b}(g^c) = \tilde{\rho}_{\alpha}^{\text{representation(charge)}}(\text{flux,flux}) \) as basis (flux). So we understand that the representation \( \rho(c) \) is constrained by the flux \( a, b \). We will consider Type IV \( \omega_{4,11} \) twisted theories, but we include \( \omega_{4,11,11} \) further multiplied by Type II \( \omega_{4,11} \). Thus, the representation also relates to their topological terms \( p_m \) of Type II \( \omega_{4,11} \) labeling \( (Z_2)^2(1) \) = \( (Z_2)^{12} \) types of theories, \( p_{l,m} \) of Type III \( \omega_{4,11,11} \) labeling \( (Z_2)^2(1) \) = \( (Z_2)^{12} \) types of theories. Totally all these 4-cocycles multiplied by \( \omega_{4,11} \) yields the \( 2^{20} \) type of theories endorsed with non-Abelian statistics. Under the Type II, Type III twists, the Type IV Rep is adjusted to:

\[
\tilde{\rho}_{a,b}(\pm,\pm) = \frac{1}{2} \sum_{l<m<n} \rho_{l,m,n} f_{l,m,n}(a,b,c) e^{i 2 \pi \frac{1}{4} F(a,b,c) + p_{l,m} f_{l,m}(a,b,c)}.
\]

Note that the trace \( \text{Tr} \tilde{\rho}_{a,b}(\pm,\pm) \) is nonzero only when (1) \( c = a, c = b \) or \( c = ab \) with \( \text{Tr} \tilde{\rho}_{a,b}(\pm,\pm) \neq 0 \), or (2) \( c = F(0) \) zero flux, i.e. \( \text{Tr} \tilde{\rho}_{a,b}(\pm,\pm)(F(0)) \neq 0 \). Other cases have zero traces. Among the degeneracy sectors on the \( \mathbb{T}^3 \) torus, we have GSD_{13} = \( (n^8 + n^9 - n^5) + (n^{10} - n^7 - n^6 + n^3) \) (ground state bases in terms of particles and string quasi-excitations), which is 1576 for \( n = 2 \). We can use \( |G|^2 = (n^4)^2 = 256 \) (doubled) fluxes to do the first labeling. Note the fluxes form a doubled basis \( (a, b) \) in \( [a, a, b] \). Among 256 fluxes, there are \( n^4 + n^5 - n = 46 \) fluxes carrying Abelian excitations, while the remained \( (n^8 - n^4 + n^5 - n^3) - 210 = 46 \) non-Abelian excitations. (Beware: the bases carry two fluxes and one charge, these bases should not be confused with string and particle types.) We may organize the ground state bases in terms of two kinds, which correspond to Abelian and non-Abelian excitations:

- \((n^4 + n^5 - n) \cdot n^4 = 46 \times 16 = 736\) Abelian excitations: \( F(j_{ab}), (a_1, a_2, a_3, a_4) \)

Here \( a = F(j_{ab}) \) can be zero fluxes, or nonzero fluxes by satisfying the following conditions:

\[
a_1 b_2 = a_2 b_1, a_1 b_3 = a_3 b_1, a_1 b_4 = a_4 b_1, a_2 b_3 = a_3 b_2, a_2 b_4 = a_4 b_2, a_3 b_4 = a_4 b_3 \quad (\text{mod} \ N)
\]

There are \((n^4 + n^5 - n)\) independent solutions for these sets of \( a, b \). The conjugacy class \( C^F(j_{ab}) \) stands for fluxes. There are \( n^4 \) representation as charges; these can be labeled by \((a_1, a_2, a_3, a_4)\) with \((a_1, a_2, a_3, a_4) \in (Z_2)^4\), and \( Z_2 = \{0, 1\} \). We will write \((a_1, a_2, a_3, a_4) = a\). Eq.(A28) becomes

\[
\tilde{\rho}_{a,b}(\pm,\pm)(e) = \tilde{\rho}_{a,b}(1)(a_1,a_2,a_3,a_4)(e) = \exp \left( \sum_{k=1}^{4} 2 \pi i n_k a_k c_k \right).
\]

For \( n = 2 \), there are \((2^4 + 2^5 - 2) = 46\) (doubled) fluxes contributing Abelian excitations.

- \((n^8 - (n^4 + n^5 - n)) \cdot n^2 = 210 \times 4 = 840\) non-Abelian excitations: \( F(j_{\text{non,ab}}), (\pm, \pm) \)

For \( n = 2 \), there are \((n^8 - (n^4 + n^5 - n)) = 210\) (doubled) fluxes contributing non-Abelian excitations. Each of them carries 2-dimensional Rep with two pairs of \((\pm, \pm)\) charge Rep. Thus the number of doubled fluxes multiplied...
by 4 yields 840 excitations. It is equivalent to count the $C_{a,b}^{(2)}(c,d)$ class that they belong to. There are six $c_d m$ terms in the Type IV 4-cocycles:

$$C_{a,b}^{(2)}(c,d) = \exp \left( \frac{2\pi i p_{IV}(1234)}{N_{a,b,m}} (a_4 b_3 - a_3 b_4) c_1 d_2 + (a_2 b_4 - a_4 b_2) c_1 d_3 + (a_4 b_1 - a_1 b_4) c_2 d_3 + (a_3 b_2 - a_2 b_3) c_1 d_4 + (a_1 b_3 - a_3 b_1) c_2 d_4 + (a_2 b_1 - a_1 b_2) c_3 d_4 \right).$$ \hfill (A31)

Below each solution will be multiplied by 6, due to $(\frac{3}{3}) \times 2$, that 3 terms $a,b,ab$ can choose 2 as the generator basis for $a, b$. Those terms have $Tr[p_{a,b}^{\pm}((\pm,\pm)) \rho(c)] \neq 0$ for $c = 0, a, b, ab$. And the permutation of $a, b$ results in an extra multiple of 2. We organize the solutions to the following six styles. Each style may contain dimensionally reduced 3-cocycles, as “Type III 3-cocycle like” or “mixed-Type III 3-cocycles.” Here “Type III 3-cocycle like” means that the dimension reduced 2D theory has an induced 3-cocycle which is a Type III 3-cocycle within a subgroup $(Z_2)^3$. “Mixed-Type III 3-cocycle” means that the dimension reduced 2D theory has an induced 3-cocycle which contains several Type III 3-cocycles spanning the full group $(Z_2)^3$. The six styles of solutions are:

- $C_{a,b}^{(2)}(c,d)$ contains 1 $cd$ term: $(\frac{6}{1}) \times 6 = 36$ non-Abelian fluxes - **Style 1** (Type III 3-cocycle like):

- $C_{a,b}^{(2)}(c,d)$ contains 2 $cd$ term: $(\frac{6}{2}) \times 3 = 6 = 72$ non-Abelian fluxes - **Style 2** (Type III 3-cocycle like):

We have $(\frac{3}{3})$ subtract 3, due to it is impossible to have nonzero coefficients $cd$ terms of $C_{a,b}^{(2)}(c,d)$ for both of the following terms together:

(1) $c_3d_4$ and $c_1d_2$ terms, (2) $c_2d_4$ and $c_1d_3$ terms, (3) $c_2d_3$ and $c_1d_4$ terms.

- $C_{a,b}^{(2)}(c,d)$ contains 3 $cd$ term: $(\frac{6}{3}) \times 6 = 48$ non-Abelian fluxes - **Style 3** (Type III 3-cocycle like), **Style 4** (mixed-Type III 3-cocycles):

- **Style 3** (Type III 3-cocycle like) $(\frac{3}{3}) \times 6$:

$(\frac{3}{3})$ out of 6 have nonzero coefficients for: (1) $c_2d_3$, $c_2d_4$, $c_3d_4$. (2) $c_1d_3$, $c_1d_4$, $c_3d_4$. (3) $c_1d_2$, $c_1d_4$, $c_2d_4$. (3) $c_1d_2$, $c_1d_3$, $c_2d_3$. Each type has 6 possible choices for $a,b$.  

- **Style 4** (mixed-Type III 3-cocycles) $(\frac{3}{3}) \times 6$:

$(\frac{3}{3})$ out of 6 have nonzero coefficients for: (1) $c_1d_2$, $c_1d_3$, $c_1d_4$. (2) $c_1d_2$, $c_2d_3$, $c_2d_4$. (3) $c_1d_2$, $c_1d_3$, $c_2d_4$. (4) $c_1d_4$, $c_2d_4$, $c_2d_4$. Each type has 6 possible choices for $a,b$.

- $C_{a,b}^{(2)}(c,d)$ contains 4 $cd$ term: $(\frac{6}{4} - (\frac{3}{3}) \cdot 3 = 3 \times 6 = 18$ non-Abelian fluxes - **Style 5** (mixed-Type III 3-cocycles):

Among 15 terms (with 4 $cd$) in $(\frac{3}{3}) = 15$, there are only 3 terms allowed.

(1) $c_1d_2$, $c_2d_3$, $c_1d_4$, $c_2d_4$, (2) $c_1d_3$, $c_2d_3$, $c_1d_4$, $c_2d_4$, (3) $c_1d_2$, $c_1d_3$, $c_2d_3$, $c_2d_3$. There are terms from $(\frac{3}{3}) \cdot 3 = 12$ is not allowed, like $c_1d_2$, $c_1d_3$, $c_2d_3$, $c_1d_4$. (i.e. choose 3 elements as $(\frac{3}{3})$ and choose one of the three, thus times 3, to pair with the remaining unchosen.)

- $C_{a,b}^{(2)}(c,d)$ contains 5 $cd$ term: $(\frac{6}{5}) \times 6 = 36$ non-Abelian fluxes - **Style 6** (mixed-Type III 3-cocycles):

$(\frac{3}{3})$ out of 6 have nonzero coefficients: (1) $c_1d_2$, $c_1d_3$, $c_1d_4$, (2) $c_1d_2$, $c_2d_3$, $c_2d_4$, (3) $c_1d_2$, $c_1d_3$, $c_2d_4$, (4) $c_1d_4$, $c_2d_2$, $c_2d_4$, (5) $c_1d_2$, $c_1d_3$, $c_2d_2$, $c_2d_4$, (6) $c_1d_3$, $c_1d_4$, $c_2d_4$, (7) $c_1d_3$, $c_1d_4$, $c_2d_2$. Those Style 1, 2, 3 are pure Type III 3-cocycle $\omega_3$ like, which $\rho_{a,b}^{ab,\pm}(c)$ can be deduced from Sec.A4 c’s $G = (Z_2)^3$ result. Style 4, 5, 6 are mixed Type III 3-cocycle in the full $G = (Z_2)^3$ group, so one needs to assign the Rep $\rho_{a,b}^{ab,\pm}(c)$ in slightly different manners. But it turns out that rank-2 matrices are always sufficient to encode the irreducible projective representation of $C_{a,b}^{(2)}(c,d)$. After finding the $\rho_{a,b}^{ab,\pm}(c)$, we analytically derive their non-Abelian $S^{xyz}$, $T^{xyz}$ of 3D presented in the main text, in Table V, Eq.(51), Eq.(52).

Appendix B: $S^{xyz}$ and $T^{xyz}$ calculation in terms of the gauge group $G$ and 4-cocycle $\omega_4$

1. Unimodular Group and $SL(N, Z)$

In the case of the unimodular group, there are the unimodular matrices of rank $N$ forms $GL(N, Z)$. $S_U$ and $T_U$
any general $N$:

$$S_u = \begin{pmatrix} 0 & 0 & 0 & \cdots & (-1)^N \\ 1 & 0 & 0 & \cdots & 0 \\ 0 & 1 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \end{pmatrix}, \quad (B1)$$

$$T_u = \begin{pmatrix} 1 & 1 & 0 & \cdots & 0 \\ 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \end{pmatrix}. \quad (B2)$$

Note that $\det(S_u) = -1$ in order to generate both determinant 1 and $-1$ matrices.

For the $SL(N, Z)$ modular transformation, we denote their generators as $S$ and $T$ for a general $N$ with $\det(S) = \det(T) = 1$:

$$S = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad T = T_u. \quad (B3)$$

Here for simplicity, let us denote $S^{xyz}$ as $S_{3D}$, $S^{xy}$ as $S_{2D}$, $T^{xy} = T_{3D} = T_{2D}$. Recall $SL(3, Z)$ is fully generated by generators $S_{3D}$ and $T_{3D}$.

$$S_{3D} = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad T_{3D} = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad S_{2D} = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \quad (B4)$$

$$S_{2D} = (T_{3D}^{-1}S_{3D})^3(S_{3D}T_{3D})^2S_{3D}T_{3D}^{-1}. \quad (B5)$$

By dimensional reduction (note $T_{2D} = T_{3D}$), we expect that,

$$S_{2D}^3 = (S_{2D}T_{3D})^6 = 1, \quad (B6)$$

$$S_{2D}T_{3D}^3 = e^\frac{2\pi i}{3}c_-, S_{2D}^2 = e^\frac{2\pi i}{3}c_-C. \quad (B7)$$

c_- carries the information of central charges. We can express

$$R = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} = (T_{3D}S_{3D})^2T_{3D}^{-1}S_{3D}^2T_{3D}^{-1}S_{3D}T_{3D}S_{3D}. \quad (B8)$$

One can check that

$$S_{3D}S_{3D}^4 = S_{3D}^3 = R^6 = (S_{3D}R)^4 = (RS_{3D})^4 = 1, \quad (B9)$$

$$S_{3D}R^2 = (R^2S_{3D})^4 = (S_{3D}R^2)^4 = (R^2S_{3D})^3 = 1, \quad (B10)$$

$$S_{3D}R^3S_{3D}^2R^2 = R^2(S_{3D}R^2S_{3D})^2 \pmod{3}. \quad (B11)$$

Such expressions are known in the mathematic literature, part of them are listed in Ref.37.
cocycles on the simplices. We find that, for $M_3$:

$$A_3 = \frac{\omega_4(g_{12}, g_{23}, g_{35}, g_{51})\omega_4^{-1}(g_{35}, g_{51}, g_{12}, g_{23})}{\omega_4(g_{23}, g_{35}, g_{51}, g_{12})\omega_4(g_{51}, g_{12}, g_{23}, g_{35})}$$

(B12)

for $M_4$:

$$A_4 = \frac{\omega_4(g_{67}, g_{78}, g_{86}, g_{78})\omega_4(g_{84}, g_{46}, g_{67}, g_{78})}{\omega_4(g_{46}, g_{67}, g_{78}, g_{86})\omega_4(g_{78}, g_{84}, g_{46}, g_{67})}.$$  

(B13)

To compute the amplitude for $M_1$, we may view $M_1$ and a composition of $M_1'$ and $M_1''$ (see Fig. 21 and 22). The amplitude for $M_1'$ is

$$A_1' = \frac{\omega_4(g_{23}, g_{35}, g_{56}, g_{62})\omega_4(g_{56}, g_{62}, g_{23}, g_{35})}{\omega_4(g_{23}, g_{35}, g_{56}, g_{62})\omega_4(g_{56}, g_{62}, g_{23}, g_{35})} \times$$

$$\frac{\omega_4^{-1}(g_{34}, g_{46}, g_{62}, g_{23})\omega_4^{-1}(g_{62}, g_{23}, g_{35}, g_{56})}{\omega_4(g_{23}, g_{34}, g_{46}, g_{62})\omega_4(g_{56}, g_{62}, g_{23}, g_{35})}.$$  

(B14)

The above eight cocycles come from eight 4-simplices as illustrated in Fig. 23. The amplitude for $M_1''$ is

$$A_1'' = \omega_4^{-1}(g_{23}, g_{35}, g_{56}, g_{62}).$$

(B15)

and the total amplitude for $M_1$ is

$$A_1 = A_1'A_1''.$$  

(B16)
where $A_2'$ is the amplitude for $M_2'$ (see Fig. 24)

$$
A_2' = \frac{\omega_4(935, 956, 967, 972') - \omega_4(935, 972', 923', 93'7')}{\omega_4(956, 967, 972', 923', 93'7') - \omega_4(946, 967, 972', 923', 94'67') - \omega_4(934, 946, 967, 972') - \omega_4(934, 967, 972', 923', 94'67')}
$$

(B18)

and $A_2''$ is the amplitude for $M_2''$ (see Fig. 25)

$$
A_2'' = \omega_4(923', 93'4', 94'6', 96'7').
$$

(B19)

Here $g_{ij}$ is the group element on the edge $(ij)$. We have

$$
g_{12} = g_{34} = g_{56} = g_{78} = g_x, \\
g_{13} = g_{24} = g_{57} = g_{68} = g_y, \\
g_{15} = g_{26} = g_{37} = g_{48} = g_z, \\
g_{23} = g_{67} = g_x^{-1}g_y, \\
g_{35} = g_{46} = g_y^{-1}g_z, \\
g_{25} = g_{47} = g_x^{-1}g_z, \\
g_{36} = g_y^{-1}g_xg_z,
$$

(B20)

$$
h_{12} = h_{34} = h_{56} = h_{78} = h_x, \\
h_{13} = h_{24} = h_{57} = h_{68} = h_y, \\
h_{15} = h_{26} = h_{37} = h_{48} = h_z, \\
h_{23} = h_{57} = h_x^{-1}h_y, \\
h_{35} = h_{46} = h_y^{-1}h_z, \\
h_{25} = h_{47} = h_x^{-1}h_z, \\
h_{36} = h_y^{-1}h_xh_z.
$$

(B21)

$$
g_{51'} = g_x^{-1}w, \\
g_{62'} = g_x^{-1}g_xw, \\
g_{84'} = wh_x^{-1}, \\
g_{65'} = g_{72'} = g_{66'} = wh_y^{-1}.
$$

(B22)

Also if the following conditions are not satisfied, the amplitude $A_{xy}^{xyz}(g_x, g_x, g_x, g_x, g_x, g_x, g_x; w)$ will be zero:

$$
g_{xw} = wh_x, \\
g_{yw} = wh_y, \\
g_{xy} = g_yg_x, \\
g_{yg}_x = g_yg_x, \\
g_{zg}_x = g_zg_x, \\
h_xh_y = h_yh_x, \\
h_yh_z = h_zh_y, \\
h_zh_x = h_xh_z.
$$

(B23)

Note the above has $g_x, g_y, g_z$ commute due to the identification on a $T^3$ torus.

4. Explicit expression of $T^{xy}$ in terms of $(G, \omega_4)$

Similar to $S^{xyz}$, we can triangulate $T^{xy}$ on $T^2 \times I$. It is easier to start with a $T^{xy}$ on $T^2 \times I$ for 2D, which we denote $T_{2D}(w)$ and triangulate in the following $3! + 1 = 7$ tetrahedra (3-simplex). Here we have the vertex ordering for the arrows: $1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 1' < 2' < 2'4' < 3' < 5' < 6' < 6'4' < 7'$. 
The last extra piece is required to change the branching structure of the 3-simplex due to \( T^{xy} \) transformation.

For \( T_{3D}(w) \), we simply have 7 pieces of slant products. Each slant product contains four 4-simplices. So totally there are 28 pieces of 4-cocycles in \( T_{3D}(w) \).

\[
T_{3D}(w) = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 4 \\
1 \quad 7
\end{array}
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 4 \\
1 \quad 7
\end{array}
\end{array}
\end{array} = (T_1)(T_2)(T_3)(T_4)(T_5)(T_6)(T_7). \tag{B25}
\]

The constraints given by \( T(w) \) are

\[
\begin{align*}
w^{-1}g_xw &= h_x, \tag{B26} \\
w^{-1}g_yw &= h_y, \tag{B27} \\
w^{-1}g_zw &= h_z. \tag{B28}
\end{align*}
\]

Below we explicitly write down seven \( T_i \), where we omit a \( w \) arrow without drawing it, which shall connect from the left 3-simplex to the right 3-simplex.

\[
(T_1) = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 7 \\
1 \quad 5
\end{array}
\end{array}
\end{array} = \omega_4([12], [23], [35], [51']) \cdot \omega_4([23], [35], [56], [61']) \cdot \omega_4([35], [56], [67], [71']) \cdot \omega_4^{-1}([56], [67], [71'], [1'5']). \tag{B29}
\]

\[
(T_2) = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 7 \\
1 \quad 5
\end{array}
\end{array}
\end{array} = \omega_4^{-1}([23], [36], [61'], [1'2']) \cdot \omega_4([36], [67], [71'], [1'2']) \cdot \omega_4^{-1}([67], [71'], [1'2'], [2'5']) \cdot \omega_4([67], [72'], [2'5'], [5'6']). \tag{B30}
\]

\[
(T_3) = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 7 \\
1 \quad 5
\end{array}
\end{array}
\end{array} = \omega_4([37], [71'], [1'2'], [2'2']) \cdot \omega_4^{-1}([71'], [1'2'], [2'2'], [2'5']). \tag{B31}
\]

\[
(T_4) = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 4 \quad 7 \\
2 \quad 6
\end{array}
\end{array}
\end{array} = \omega_4^{-1}([23], [34], [46], [62']) \cdot \omega_4^{-1}([34], [46], [67], [72']) \cdot \omega_4^{-1}([46], [67], [78], [82']) \cdot \omega_4([67], [78], [82'], [2'6']). \tag{B32}
\]

\[
\begin{align*}
T_{2D}(w) &= \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 4 \\
1 \quad 2
\end{array}
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 4 \\
1 \quad 2
\end{array}
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 4 \\
1 \quad 2
\end{array}
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
3 \quad 4 \\
1 \quad 2
\end{array}
\end{array}
\end{array} \tag{B24}
\end{align*}
\]

\[
\omega(w) = (\omega_1(4) - \omega_1(2) - \omega_1(1) - \omega_1(3)) = (\omega_1(3) - \omega_1(4) - \omega_1(2) - \omega_1(1)) = (\omega_1(1) - \omega_1(3) - \omega_1(2) - \omega_1(4)).
\]
$$(T_5) = \begin{array}{c} 3 \hspace{1cm} 2^* \hspace{1cm} 4 \hspace{1cm} 7 \hspace{1cm} 8 \end{array}$$

$$(T_6) = \begin{array}{c} 2^* \\ 2^* \\ 3' \\ 6^* \\ 7' \\ 8 \\ 6 \\ 5' \end{array}$$

$$(T_7) = \begin{array}{c} 2^* \\ 3' \\ 6^* \\ 7' \end{array}$$

For the tricky $T_7$, we shift 1’ to a new later time slice 1”, and shift 5’ to a new later time slice 5”:

$$(T_7) = \begin{array}{c} 2^* \\ 3' \\ 6^* \\ 7' \end{array}$$

$$(T_7) = \begin{array}{c} 2^* \\ 3' \\ 6^* \\ 7' \end{array}$$

$$(T_7) = \begin{array}{c} 2^* \\ 3' \\ 6^* \\ 7' \end{array}$$

$$(T_7) = \begin{array}{c} 2^* \\ 3' \\ 6^* \\ 7' \end{array}$$

$$(T_7) = \begin{array}{c} 2^* \\ 3' \\ 6^* \\ 7' \end{array}$$

One can also define the projection operator on $\mathbb{T}^3$ as

$$P_{3D}(w) = (T_1)(T_2)(T_3)(T_4)(T_5)(T_6).$$

Once obtaining the path integral of 4-cocycles, we can change the flux basis to the canonical basis, and follow the procedure outlined in the Appendix of Ref.50 to derive the Rep theory formula given in our main text Sec.III.B. An additional remark - an easier way to check the consistency for formulas of S, T is to use the rules in AppendixB1 and to apply the discrete Fourier transform of a finite group such as:

$$\frac{1}{|G|} \sum_{b,d,\beta} tr_{\beta}^{b,d}(a) tr_{\beta}^{b,d}(e)^* = \delta_{a,e},$$

$$\frac{1}{|G|} \sum_{a,b,d} tr_{\alpha}^{a,b}(d)* tr_{\gamma}^{a,b}(d) = \delta_{a,\gamma}.$$
