Abstract

A limited supply of pine bark (PB) over the past several years has caused concern among many nursery producers. In continuing the search for alternative substrates and working to quantify the extent to which substrates can be amended with high wood content alternatives, this study was developed to evaluate substrate treatments comprised of PB with 25, 50, and 75% clean chip residual (CCR) or WholeTree substrate (WT), as well as 100% substrates of each high wood fiber substrate. By 180 and 365 DAT, pH and electrical conductivity (EC) values for all treatments were similar to those of the 100% PB control. Growth data at 365 days after planting (DAT) showed that with all nursery crops tested, nursery producers could use 75% CCR or 75% WT in their standard PB substrate with limited impact on crop growth. The purpose of this study was to allow nursery producers the opportunity to become comfortable using CCR or WT as amendments before switching completely to 100% alternative substrates.

Index words: media, alternative, amendment, nursery, container-grown.

Species used in this study: ‘New Gold’ lantana (Lantana camara L. ‘New Gold’); ‘Gold Mound’ spirea (Spiraea japonica L.f. ‘Gold Mound’); ‘Amaghasa’ azalea (Rhododendron × ‘Amaghasa’ L.); tea olive (Osmanthus fragrans Lour.); ‘Rotundifolia’ ligustrum (Ligustrum japonicum Thunb. ‘Rotundifolia’); ‘Soft Touch’ holly (Ilex crenata Thunb. ‘Soft Touch’).

Significance to the Nursery Industry

With the recent decline of pine bark (PB) supplies, and the threat of continued decline, nursery growers need alternative components or amendments for their standard growing substrate. Clean chip residual (CCR) and WholeTree substrate (WT) are two possible alternative substrates with commercialization possibilities. This study demonstrated that woody nursery crops grown in varying ratios of PB:CCR and PB:WT had similar growth to plants grown in a current nursery standard of 100% PB. This information will allow growers to develop plans for extending existing PB supplies with CCR or WT.

Introduction

Due to a number of factors, PB supplies have significantly decreased over the past few years. While alternative substrates have been evaluated (3, 4, 5, 6, 7, 8, 9, 11, 18), many growers are asking if these alternative substrates can be used to stretch existing PB supplies. In this study, two alternative substrates, CCR and WT were evaluated as amendments to PB to determine their effect on the growth of six common nursery crops. Both CCR and WT contain higher wood content than PB alone. CCR is composed of approximately 50% wood, 40% bark, and 10% needles (4), and is created when transportable in-field harvesters are used to process pine trees into ‘clean chips’ that are used by pulp mills. CCR is a by-product of pulp wood processing that is either sold for boiler fuel or more commonly, spread back across the harvested area. Several studies have been conducted to evaluate CCR as a viable alternative substrate. Three annual species (‘Blue Hawaii’ ageratum (Ageratum houstonianum Mill.), ‘Vista Purple’ salvia (Salvia ×superba Sellow ex J.A. Schultes), and ‘Coral’ or ‘White’ impatiens (Impatiens wallerana Hook.)] were evaluated in a greenhouse setting (5) in nine substrate treatments comprised of PB, peat moss, and CCR blends. At study termination, growth for two of the
three species was similar to standard PB substrates. Boyer et al. (4) evaluated eight perennial species in Auburn, AL, for growth in CCR; species evaluated included ‘Pink Delight’ buddleia (Buddleia davidii ‘Pink Delight’ Franch.), ‘Siskiyou Pink’ gaura (Gaura lindheimeri ‘Siskiyou Pink’ Engelm. & A. Gray), ‘Sweet Dreams’ coreopsis (Coreopsis rosea ‘Sweet Dreams’ Nutt.), ‘Homestead Purple’ verbena (Verben a canadensis ‘Homestead Purple’ (L.) Britt.), ‘Butterfly Blue’ scabiosa (Scabiosa columbaria ‘Butterfly Blue’ L.), ‘Firewitch’ dianthus (Dianthus gratianopolitanus ‘Firewitch’ Vill.), ‘Irene’ rosemary (Rosmarinus officinalis ‘Irene’ L.), and ‘Black and Blue’ salvia (Salvia guaranitica ‘Black and Blue’ St.-Hil. ex Benth.). The study was duplicated in Poplarville, MS, with few differences in growth at the conclusion of the study for most species. Growth indices were similar at Poplarville for 6 of 8 species and for 3 of 7 species at Auburn. In 2009, Boyer et al. (6) also reported on the use of CCR as a nursery crop substrate for container-grown ornamentals at several screen sizes (3.18, 1.91, 1.27, and 0.95 cm) (1.25, 0.75, 0.50, and 0.375 in, respectively). Five species were tested, including Loropetalum chinensis var. rubrum R. Br., Buddleia davidii ‘Black Knight’ Franch., Lagerstroemia indica L., ‘Hopi’, Lagerstroemia ‘Fauriei’ ‘Natchez’ Walfich ex Paxt., and Rhododendron indicum ‘Mrs. G.G. Gerbing’. The study was conducted in two locations; Auburn, AL, and Poplarville, MS. Few differences were reported among loropetalum, buddleia, lagerstroemia, and rhododendron plants grown in CCR, compared to PB treatments. However, data indicated that treatments with larger particle sizes tended to have higher air space percentages, as well as lower water holding capacity percentages. Their data also indicated that root growth was greater in treatments with smaller particle sizes. Consistency among pH and EC levels suggested that CCR would be a dependable substrate comparable to PB.

The WT substrate (80% wood, 15% bark, 5% needles) is different from CCR in that it consists of the entire pine tree harvested from pine plantations at the thinning stage, therefore having a higher wood content than CCR (9). Just as with CCR, several studies have been conducted to assess the value of WT as a comparable substrate to traditional PB. In 2006, Fain and Gilliam reported that annual vinca (Catharanthus roseus (L.) G.Don ‘Little Blanche’) grown in WT had similar growth to plants grown in PB (7). While shoot dry mass was 15% higher for plants grown in 100% PB 60 days after planting, there were no differences in plant growth indices. Another study evaluating WT in production of five herbaceous greenhouse crops indicated that growth varied with the crop produced, but also showed that WT could have potential for becoming an acceptable, and highly economical, alternative to traditional peat moss based substrates (8). Plants were grown in treatments containing 100% WT ground to three different screen sizes (0.375, 0.25, or 0.187 in), as well as in treatments containing 1:1 and 4:1 WT:peatmoss ratios. At 34 DAP, there were no differences in flower number for marigold; however, lantana grown in 100% WT substrates had the fewest flowers. Petunias grown in an industry standard peat blend substrate had over twice the number of flowers than was observed on plants grown in other substrates. In general, plants grown in WT substrates were smaller than plants in other blends, but plants increased in size with increasing percentages of peat moss.

A recent study by Jackson et al. (2010) reported on the results of substrate physical properties and plant growth in treatments with combined amounts of wood particle sizes. Results from that study indicated that by combining no less than 50% small-particle-sized pine tree substrate (produced from whole pine trees that are chipped and ground, or with CCR) with that of coarse particles of pine tree substrate, an adequate container capacity of between 45–65% could be obtained (11). Their study also evaluated plant growth in pine tree substrate amended with either 10% sand, 25% peatmoss, 25% aged pine bark, or a sand/pine bark mix. The authors noted that while some differences occurred with respect to shoot dry weight, growth index, and root ratings, all plants performed well and exhibited no nutritional-related disorders.

While previous studies have indicated the possibilities of using CCR or WT as an alternative to PB in container production, many growers are uncomfortable with making such a drastic switch in substrate material. They are interested in the possibilities of adding CCR or WT to their existing PB, and want to know how much they could amend their PB in order to stretch their supplies, as well as any differences in performance between CCR and WT. Therefore, the objective of this study was to determine the extent to which PB could be amended with either CCR or WT without reducing plant growth of six woody ornamental species.

Materials and Methods

Nine substrate treatments utilizing varying levels of PB, CCR, and WT were evaluated. CCR and WT used in the study were each processed to pass through a 0.95 cm (3/8 in) screen. Treatments consisted of 100% PB, WT, and CCR, 75:25 PB:CCR, 50:50 PB:CCR, or 25:75 PB:CCR (v:v). PB:WT substrates had the same ratios as PB:CCR. All substrates were pre-incorporated with a 6:1 (v:v) ratio of sand, and amended with 8.3 kg m−3 (14 lb yd−3) 18N-2.6P-9.9K (18-6-12) Polyon (Harrell’s Fertilizer, Inc., Lakeland, FL) control release fertilizer (9 month), 3.0 kg m−3 (5 lb yd−3) dolomite limestone, and 0.9 kg m−3 (1.5 lb yd−3) Micromax (The Scotts Company, Marysville, OH).

Six species were used in the experiment, which was initiated on July 22, 2008. Species included ‘New Gold’ lantana (Lantana camara L. ‘New Gold’), ‘Gold Mound’ spirea (Spiraea japonica L.f. ‘Gold Mound’), ‘Amaghasa’ azalea (Rhododendron × ‘Amaghasa’), tea olive (Osmanthus fragrans Lour.), ‘Rotundifolia’ ligustrum (Ligustrum japonicum Thunb. ‘Rotundifolia’), and ‘Soft Touch’ holly (Ilex xcrenata ‘Soft Touch’). Liners were transplanted from standard 32-cell packs into #1 containers and watered using overhead irrigation (1.27 cm day−1) (0.5 in day−1). Average pH of the irrigation water was between 6.7 and 7.0 for the duration of the study. Irrigation water electrical conductivity (EC) was 0.2 mS cm−1, while alkalinity (HCO₃− mg liter−1) was 80. All species were placed in full sun, except for ‘Amaghasa’ azaleas, which were placed under a 30% shade structure.

The experimental design was a randomized complete block design with 7 single pot replications per treatment. Each species was treated as its own separate experiment. Physical properties and particle-size distribution (PSD) were evaluated at the USDA-ARS Southern Horticultural Laboratory in Poplarville, MS (n = 3). Physical properties [substrate air space (AS), water holding capacity (WHC), total porosity (TP)] were determined using the North Carolina State University porometer method (10). Bulk density (BD) was determined from 347.5 cm³ samples dried in a 105C (221F)
forced air oven for 48 hours. The PSD was determined by passing a 100 g air-dried sample through a series of sieves. Sieves were shaken for three minutes with a Ro-Tap (Ro-Tap RX-29, W.S. Tyler, Mentor, OH) sieve shaker. Shrinkage of substrates was evaluated at 15, 120 and 365 DAT by measuring distance (in cm) from the top of the pot to the top of the substrate. Leachates were collected from 'Amaghasa' azalea plants using the Virginia Tech PourThru technique (17). pH and EC (mS cm⁻¹) were measured at 7, 15, 30, 60, 90, 120, 180 and 365 days after transplanting (DAT). Growth indices [(height + width₁ + width₂)/3] (cm) were measured at 90 and 365 DAT. Leaf chlorophyll content was quantified using a SPAD-502 chlorophyll meter (Minolta Camera Co., Ramsey, NJ) at 30, 120 and 365 DAT. Root growth and general health was assessed at study termination (365 DAT) on a scale from 1–5, where 1 was assigned to plants with less than 20% root ball coverage, and 5 was assigned to plants with between 80–100% root ball coverage. Tissue nutrient content was determined using 25–30 recently matured leaves of lantana (n = 4). The concentration of nitrogen (N) in the leaves was determined by conducting combustion analysis using a 1500 N analyzer (Carlo Erba, Milan, Italy). Remaining macronutrients, as well as micronutrients (phosphorus (P), potassium (K), calcium (Ca), magnesium (Mg), manganese (Mn), zinc (Zn), copper (Cu) and boron (B)) were quantified by microwave digestion with inductively coupled plasma-emission spectrometry (Thermo Jarrel Ash, Offenbach, Germany). Data were analyzed using Tukey’s Studentized Range Test (p ≤ 0.05) in a statistical software package (SAS® Institute version 9.1.3, Cary, NC) (2). Studies were conducted at the AU Paterson Greenhouses at Auburn University, AL.

Results and Discussion

Physical properties. With only one exception at 36.4% (by vol) (75:25 PB:CCR), all container substrate AS percentages were within recommended ranges (10–30%) (16) (Table 1). Values were between 25 and 36.4%, with the lowest percentage at 25.1% (75:25 PB:WT). Subsequently, percent WHC for substrate treatments tended to be toward the low end of the recommended range of 45–65%. Treatments with WHC percentages below the recommended range included 100% PB (40.7%) and 100% WT (40.7%), as well as most treatments containing CCR. The only treatments within the WHC recommended range (45–65%) were 75:25 PB:WT (46.9%), 50:50 PB:WT (46.3%), 25:75 PB:WT (46.9%), and 25:75 PB:CCR (45.0%). The recommended range for TP in a container substrate is 50–85%. All treatment percentages of TP were similar to the 100% PB industry standard except for 75:25 PB:CCR (75.9%). Also with respect to TP, all v:v ratios of PB:WT were similar to their PB:CCR counterparts.

Particle size distribution analysis was broken down into three texture sizes, coarse (3.35–9.50 mm), medium (1.00–2.36 mm), and fine (0.00–0.50 mm). Particles greater than 3.35 mm afford aeration to container substrates (15). There were no differences in the amount of coarse particles of any substrate treatment (Table 2). Medium particles were greatest in substrates with increased levels of CCR (25:75 PB:CCR and 100% CCR, 41.4 mm and 44.9 mm, respectively). Medium particles were least in 100% PB (32.9 mm) and 75:25 PB:WT (34.1 mm). Only two treatments (75:25 PB:WT and 25:75 PB:WT, 34.1 and 36.3 mm, respectively) had similar amounts of medium particles compared to that of the 100% PB industry standard (39.2 mm). Fine particles in a container substrate greatly influence substrate water holding capacity (1). Container substrates with increased fine particles will often become water-soaked, while container substrates with too few fine particles will often dry out more

Table 1. Physical properties of nine substrates containing pine bark, clean chip residual, and WholeTree substrate.

| Substrate | Air space (%) | Substrate water holding capacity (%) | Total porosity (%) | Bulk density (g cm⁻³) |

| 100% WT   | 25.9b         | 40.7cd                              | 66.6b             | 0.41bc              |

*Analysis performed using the North Carolina State University porometer (http://www.ncsu.edu/project/hortsublab/diagnostic/porometer/).
*PB = pine bark, CCR = clean chip residual, WT = WholeTree.
*Air space is volume of water drained from the sample / volume of the sample.
*Substrate water holding capacity is (wet weight - oven dry weight) / volume of the sample.
*Total porosity is substrate water holding capacity + air space.
*Bulk density after forced-air-drying at 105°C (221.0°F) for 48 hrs; 1 g cm⁻³ = 62.4274 lb ft⁻³.
*Means within column followed by the same letter are not significantly different based on Tukey’s Studentized Range Test at α = 0.05 (n = 3).
*Recommended ranges as reported by Yeager, et al., 2007. Best Management Practices Guide for Producing Container-Grown Plants.
quickly than desired (1). All substrate treatments had similar fine particle weights to that of the nursery standard, 100% PB (46.7 mm).

Shrinkage. No differences occurred for shrinkage between any container substrate treatment at any of the three testing dates (15, 180 and 365 DAT) (data not shown). Throughout the study, shrinkage for all substrates increased steadily for an overall average of 1.53 cm. This is most likely due to the natural settling of the substrate in the container. Settling may be increased due to the large amount of air space in each substrate. Some shrinkage may also be due to microbial activity (12).

pH and EC. With few exceptions, substrate pH remained within BMP recommended levels of 4.5–6.5 (16) for the duration of the study (Table 3). Increasing levels of CCR and WT tended to raise substrate pH compared to PB alone. While pH of 100% WT substrate was slightly out of the desired range at 30 and 60 DAT, pH levels were well within range. Only at three times were pH levels of substrates with CCR out of the recommended range [25:75 PB:CCR at 15 DAT (6.7), 100% CCR at 60 DAT (6.6) and 100% CCR at 120 DAT (6.6)]. At both 180 and 365 DAT, no treatment had dissimilar pH values than that of the 100% PB industry standard. Data indicates that CCR and WT additives may be increased due to the large amount of air space in each substrate. Some shrinkage may also be due to microbial activity (12).

*Means not significantly different.
**Means within column followed by the same letter are not significantly different based on Tukey’s Studentized Range Test at α = 0.05 (n = 7).

Plant growth in substrates amended with up to 75% alternative substrate (either CCR or WT) was acceptable and comparable to those grown in 100% PB industry standard for all species tested. Nursery producers are interested in the finished product, and whether or not that finished product is any different from ones they have been growing for years. These data indicate that growers could amend their standard PB substrate with up to 75% CCR or WT with little difference in plant growth and overall root health compared to plants grown in a PB substrate.

Table 5. Tissue nutrient content of Lantana camara L. 'New Gold' grown in nine substrates containing pine bark, clean chip residual and WholeTree substrate.

| Substrate   | N (%) | P (%) | K (%) | Ca (%) | Mg (%) | Mn (ppm) | Zn (ppm) | Cu (ppm) | B (ppm) |
|-------------|-------|-------|-------|--------|--------|----------|----------|----------|---------|
