ABSTRACT: The microbial load on smoked fish sold in Ibadan, Oyo State was studied. 64 of 4 different fish species (Mackerel (Scomber scombrus), Sardinine (Sardinella ehs), Paula (Gadus morhua) and Cat fish (Clarias gariepinus)) were sourced from five different market locations. The microbiological analysis was done using standard microbiological procedures. The bacterial count of fish sampled from Ojo market was the highest (0.35±0.11 x 10^3 CFU/g) while the bacteria count of the fish sample from Bodija market was the lowest (0.07±0.04 x 10^3 CFU/g). There was no significant difference (p>0.05) in the microbial load of the various fish species sold within Ibadan metropolis as well as fish sampled from various market locations in Ibadan metropolis. Bacterial isolated on smoked fish studied were: E. coli, Salmonella spp, Klebsiella spp, Staphylococcus aureus, Aeromonas spp, Pseudomonas spp, Vibrio spp, Serratia spp, Chromobacterium spp, Enterobacteria spp and Shigella spp. While the following fungi were isolated from the study: Aspergillus flavus, Penicillium spp, Fusarium oxysporum, Trichoderma spp and Cestrichium albldium. Fish species sold in different markets within Ibadan metropolis is fit for human consumption. Caution should be exercised in consuming smoked-dried fish displayed openly, reheating may be necessary to activate such micro-organisms before consumption.

Keywords: bacteria, fungi, market, fish species

Consumption of fish and fish products is recommended due to good digestibility and the high content of polyunsaturated fatty acids. Fishes are a rich source of protein commonly consumed as an alternative source of protein due to the higher cost of meat and other sources of animal protein (Oluwaniyi and Dosumu, 2009). Fish has lower cholesterol content when compared with meat and thus often recommended for consumption especially among the adult population (Harris, 1997). The marine fish is generally cheaper and more abundant when compared with fresh water fishes, which are relatively more expensive in Nigeria (Oluwaniyi and Dosumu, 2009). Fish is a highly perishable food and so, many strategies have been developed to limit its spoilage (Gómez-Estaca et al., 2009). According to Kumolu-Johnson et al. (2010) various food preservation techniques have been utilized to improve the microbial safety and extend the shelf-life of fish in general including freezing, chemical preservation, salting, smoking, frying and filleting. However, smoking is the most popular method of fish processing (Bako, 2004). Food is considered to be microbiologically unsafe owing to the presence of microorganisms which may invade human body (e.g Salmonella, Escherichia coli, Listeria monocytogenes, etc) and also those that produce toxins ingested with a food such as Staphylococcus aureus, Clostridium botulinum and Bacillus cereus (Ofred, 2009). The growth of these pathogens may not necessarily results in food spoilage. Hence the absence of deleterious sensory changes cannot be used as an indicator for food microbiological safety (Border and Norton, 1997). Consequently many outbreaks are caused by bacteria originating in the animal/human reservoir including Salmonella, Shigella, E. coli, and Staphylococcus aureus, (Huss et al., 1997). Generally fish and shellfish are common vehicles of transmitting food borne diseases. It is known that the primary source of cholera is feces of infected persons and transmission of bacteria with water and food. However, at present it has also been found that in certain areas the aquatic environment is a natural reservoir (habitat) for Vibrio cholerae. Microbiologists are of the opinion that the presence of Escherichia coli in food indicates the probability of contamination of the food products with the sewage of human or animal origin (Ofred, 2009). Data on risk factors for foodborne diseases indicate

*Corresponding E-mail: ayeloja2@gmail.com, aye_ayo@yahoo.com
that the majority of outbreaks result from
inappropriate food handling practices (Jones and
Angulo, 2006). Incidences of food borne disease
outbreaks are been reported each year in Kenya
(Githiri et al., 2009). However, there is scarcity of
information on occurrences of pathogens on fish and
other ready to eat food in Nigeria thus the need for this
study with the objective of determining some
microorganisms that are prevalent on smoked fish sold
in markets in Ibadan Oyo State Nigeria.

MATERIALS AND METHODS
Sample Collection: 3 replicates of 4 different smoke
dried fish including Mackerel (Scomber scombrus),
Sardine (Sardina eba), Panla (Gadus morhua) and
Cat fish (Clarias gariepinus) were purchased from 5
different markets; OJoo, Apata, Iwo-road, Bodija and
Omi-Adio, in Ibadan, Oyo state South-Western
Nigeria (totaling 60 fishes). The fish samples were
collected and kept in sterile polythene bags for
microbial analysis.

Preparation of Materials: The working tables were
swabbed with ethanol to disinfect them. All the wares
were washed and air-dried after which they were
sterilized in hot air oven at 160°C for 1 hour. Culture
media like nutrient agar was prepared according to
manufacturers’ specifications and distilled water used
for serial dilution was sterilized in an autoclave at
121°C for 15 minutes before use.

Preparation of agar plate: The agar plates were
prepared by first sterilizing the petri dishes. This was
done by putting the petri dishes in petri dish cans in
the hot air oven at 160°C for 1 hour. The sterilized
plates were then left in petri dish cans until required,
the wire loop was sterilized by flaming in red-hot fire
using a spirit lamp. The agar were prepared by
dissolving 0.6g of the agar in 100ml distilled water and
the sterilize using a microwave at 121°C for 15 min and
left to cool to 45°C.

Preparation of fish samples for microbiological tests:
Fish samples were collected in triplicates from the
samples bought from different markets. The fish were
minced after which serial dilution was made, total
viable count was done, colonies on the plates were
picked and sub-cultured and then identified.

Serial dilution: 10g of each fish sample were weighed
aseptically and homogenized in 90ml sterile peptone
water. Then, serial dilutions was made by mixing
1.0ml of the suspension in 9.0ml sterile peptone water
to obtain 10^{-1} dilution. The dilution was then made to
10^{2}, and 10^{3} diluents, then spread-plated on plates of
nutrient agar (for total viable counts); Salmonella-
shigella agar (for Salmonella and Shigella species); Mannitol salt agar (for Staphylococcus spp); Listeria
agar base (for Listeria monocytogenes); MacConkey
agar (for E. coli and other enteric bacteria); Robertson
cooked meat medium (for Clostridium botulinum) and
Eosin Methylene blue agar (for enteric bacteria). The
plates was triplicated and incubated at 37°C for
24 hours. Total number of cells per gram of samples
were then estimated after counting the colonies on the
plates. Colonies on the plates were then picked and
sub-cultured on nutrient agar plates to ensure purity of
cultures. The different pure cultures were then
transferred to nutrient agar slopes and then identified.

Characterization and identification of the isolates:
Bacterial isolates were characterized using routine
microbiological procedures as described by Olutiola et
al. (1991); Fawole and Osho (1995) after which they
were identified using Bergey’s Manual of
Determinative Bacteriology. The microbiological
identification procedures used include:

Colony morphology: This involve the microscopic
evaluation of the characteristics of bacteria colonies on
the agar plates. The characteristics considered include
the shape of the colony, elevation of the colony, edge
of the colony, colony surface pigmentation and the
optical characteristics.

Cell morphology: This shall involve staining of the
isolates to show the cell shape and appearance. In this
study, gram staining method was carried out on each
isolate. This involve studying the isolates under the oil
lens immersion microscope after gram-staining. A thin
smear of each isolate was made and heat-fixed. The
heat-fixed smears was covered with crystal violet for
about 1 minute and immediately rinsed with clean
water. The smear was then flooded with iodine for 1
minute and then rinse immediately. The smear was
then decolorized for 10 – 30 sec using 95% ethyl
alcohol. Alcohol action was terminated by rinsing the
slide with clean water, then the smear was counter-
stained with safranin for 30 seconds and then it was
rinsed off using clean water and after which it was
allowed to air dry. The stained slides were examined
under the microscope (with the aid of immersion oil)
for results. Gram-positive organisms appeared in
purple while gram-negative organisms appeared in
pink or red.

Motility test: This was carried out using hanging drop
method (Fawole and Osho, 1995). Here, a clean
depression slide and cover glass was used, they were
washed and rinsed to provide a grease-free slide. Then
a very small amount of Vaseline was placed near each
corner of the cover slide. Two loopful of the isolate

AYELOJA, AA; GEORGE, FOA; JIMOH, WA; SHITTU, MO; ABDULSALAMI, S A
were placed in contact with the cover glass with the depression slide put over the drop of suspended bacteria. The slide was quickly inverted and examined under the microscope, then the motion of the organisms were observed.

Biochemical Test: Some of the biochemical test carried out include: catalase test, indole test, citrate test sugar fermentation test and oxidase test.

Statistical Analysis: The results are expressed as means and standard deviation and analysed using two ways analysis of variance (randomized complete block design) using SPSS version 17.0 where significant difference (p<0.05) recorded. Duncan multiple range test was used to separate the means.

RESULTS AND DISCUSSION
The microbial load on fish from different market locations in Ibadan metropolis are presented in Figure 1. The highest bacteria load was recorded on fish samples from Ojo market followed by those from Apata market while the lowest bacterial count was recorded on fish samples from Bodija market.

Fig 1: Microbial Load on Fish from Different Market Location in Ibadan Oyo state

The result in table 1 show that the highest fungi count was recorded on fish samples from Omi market (0.05±0.07 x 10³ CFU/g) followed by those samples from Apata market (0.04±0.07 x 10³ CFU/g) while the lowest fungi count was recorded on fish samples from Ojo market (0.16±0.10 x 10³ CFU/g). The highest bacterial load on different fish types within Ibadan metropolis as presented on figure 2 was recorded on Panla (Gadus morhua) with the value 0.27±0.19 x 10³ CFU/g, followed by sardine (Sardinela eba) with value 0.27±0.19 x 10³ CFU/g while the lowest bacteria count was recorded on catfish (Clarias gariepinus) samples with value 0.14±0.10 x 10³ CFU/g. Also, represented in figure 2 was the fungi load on different fish types in Ibadan metropolis. The highest fungi count of 0.09±0.07 x 10³ CFU/g was recorded on sardine (Sardinela eba) followed by 0.08±0.12 x 10³ CFU/g recorded for catfish (Clarias gariepinus) and Panla (Gadus morhua) while the lowest fungi count of 0.06±0.04 x 10³ CFU/g was recorded Mackerel (Scomber scombrus). However, there is no significant difference (P>0.05) on the microbial load of the different fish species sold in Ibadan metropolis.

Fig 2: Microbial Count on Different Fish Type in Ibadan Oyo State

Table 1: Microbial Load on Fish from Different Market Location in Ibadan

| Market     | TVC (CFU/g)  | Fungi (CFU/g) |
|------------|--------------|---------------|
| Ojo        | 0.35±0.11 x 10³ | 0.16±0.10 x 10³ |
| Bodija     | 0.07±0.04 x 10³ | 0.05±0.07 x 10³ |
| Iwo-road   | 0.12±0.10 x 10³ | 0.08±0.05 x 10³ |
| Apata      | 0.30±0.20 x 10³ | 0.04±0.07 x 10³ |
| Omi        | 0.22±0.32 x 10³ | 0.05±0.07 x 10³ |
| SEM        | 0.04          | 0.02          |

Column mean with the same superscript are not significantly different (p>0.05)

Table 2: Microbial count different fish species sampled

| Fish spp  | TVC (CFU/g)  | Fungi (CFU/g) |
|-----------|--------------|---------------|
| Mackerel  | 0.19±0.22 x 10³ | 0.06±0.04 x 10³ |
| Catfish   | 0.14±0.10 x 10³ | 0.08±0.12 x 10³ |
| Panla     | 0.27±0.19 x 10³ | 0.08±0.71 x 10³ |
| Sardine   | 0.25±0.20 x 10³ | 0.09±0.07 x 10³ |
| SEM       | 0.04          | 0.02          |

Column mean with the same superscript are not significantly different (P>0.05)

The result of this study (table 1) indicate that there is no significant difference (P>0.05) on the microbial load of fish sampled in the different market location meaning that the fish sold in different markets in Ibadan Oyo state have similar microbial load which still fall within the recommended microbial limit in the guidelines for the microbiological quality of various...
ready-to-eat foods by Gilbert (2000) and Taoukis et al. (1999) that is the fish sold in the various markets in Ibadan is fit for human consumption. The microbial load on the various fish spp still fall within the recommended microbial limit in the guidelines for the microbiological quality of various ready-to-eat foods by Gilbert (2000) and Taoukis et al. (1999). Result obtained from the study showed that Aspergillus flavus, Geotricium albidium, Trichoderma sp., Fusarium oxysporium, Penicillium spp, Aeromonas spp, Klebsiella oxytoca, Leivinae spp, Serratia rubidaea, Proteus vulgaris, Shigella flexneri, Enterobacter aerogenes, Vibrio cholerae, Escherichia coli, Salmonella arizonae, Streptobacillus moniliforms, Bacteria necrophorus, Pseudomonas amattophillia and Chromobacterium violaceum, are the microorganisms found to be associated with smoke dried fishes sold in different market in Ibadan. The presence of all these bacteria and fungi may make its consumption hazardous to health as some of these microorganisms have been reported by other authors has been hazardous for human consumption. Fawole and Osho (1995) reported that Spoilage of fish is mainly due to the activity of psychrotrophic gram-negative bacteria such as Shewanella putrefaciens and Pseudomonas spp. Akande and Tobor (1999) also reported that fish and fish products spoil by different specific spoilage organisms (SSO) depending on the final treatment or preservation and storage temperature. Examples of SSO in different fish and fish products include Pseudomonas, Shewanella putrefaciens, Photobacterium phosphoreum, Aeromonas hydrophila, and Alteromonas putrefaciens, Vibrioaceae, Aeromodans, Moraxella, Acinetobacter, Enterobacteriaceae; and Yeast and molds. According to Ayeloja et al. (2011), in artisanal fishery, freshly caught fish are covered with damp sacks and at times they are mixed with wet grass or water weeds to reduce the temperature. Fish treated this way is prone to contamination with microorganisms such as Salmonella and Aspergillus. This indicates that spoilage of fish starts right from the aquatic ecosystem. Processed fishes are also prone to microbial attack especially in artisanal fishery due to unhygienical method of processing and preservation. During the smoke drying period, smoking kilns used in artisanal fishery and overloading of the fishes on the trays lead to improper processing which in turns encourage fungal attack. During storage of smoked dried fish product, good storage practices are not adhered to by fish mongers hence stores are not well ventilated and pest can easily gain access into the stores. The environment in which fishes are displayed in the market is not always hygienic and this is another avenue for microbial contamination very often, retailers’ display the smoke dried fish sample in open trays beside the gutter or refuse heaps, this also encourages fungi and bacteria attack and subsequent production of toxins. This is an agreement with the report of Ayeloja et al. (2011).

Conclusion: The study revealed that smoked-dried fishes in Omi, Iwo Road, Bodija, Ojoo and Apata markets in Ibadan Oyo State are contaminated with micro-organisms. However, the microbial load still fall within the recommended microbial limit for ready-to-eat foods indicating that the fish sold in different markets within Ibadan metropolis is fit for human consumption. The microbial load on different fish spp in Ibadan metropolis are not significantly different (p > 0.01) from each other. It is therefore recommended that fish stores should be well screened and ventilated so as to avoid contamination of smoked fish products.
