Key Words
Pancreatic stellate cells • Pancreatic fibrosis • Nuclear factor-kappaB • PI3K/AKT • Sonic hedgehog • Alpha-smooth muscle actin

Abstract

\textbf{Background:} Eruberin A (2, 3-dehydroflavonoid), a flavanol glycoside isolated from \textit{Pronephrium penangianum}, has been used as a blood-nourishing folk medicine for centuries; however, it indeed possesses a variety of other health-promoting benefits including anti-fibrotic bioactivity. Activation of pancreatic stellate cells (PSCs) is the key initiating step in pancreatic fibrosis, which is a characteristic feature associated with chronic pancreatitis and pancreatic adenocarcinoma. \textbf{Methods:} The anti-fibrotic effect of eruberin A and the underlying mechanisms of its anti-fibrotic action in LTC-14 cells, which retained essential characteristics and morphological features of primary PSCs, were examined by means of real-time polymerase chain reactions, Western blotting and immunostaining. \textbf{Results:} The application of eruberin A (20 μg/ml) effectively inhibited the expression levels of fibrotic mediators namely alpha-smooth muscle actin, fibronectin and type I-collagen, so as the sonic hedgehog signaling pathway components post transforming growth factor-beta (5 ng/ml) stimulation. Eruberin A treatment also led to a notable decrease in the activation of nuclear factor-kappaB (NF-κB) and the phosphorylation of phosphoinositide 3-kinase (PI3K)/serine-threonine kinase (AKT). \textbf{Conclusion:} Our results demonstrated that eruberin A significantly suppressed the expression levels of fibrotic mediators in PSCs, and we suggest that its anti-fibrotic mechanism was associated with an attenuation of the PI3K/AKT/NF-κB signaling pathway.
Introduction

Pancreatic fibrosis, an active dynamic process that results in irreversible morphological scarring of the pancreatic parenchyma, is often accompanied with chronic pancreatitis and desmoplastic reaction of pancreatic ductal adenocarcinoma (PDAC) [1, 2]. The activation of pancreatic stellate cells (PSCs) is suggested to be the most crucial initiating step of the progressive fibrotic cascade [1, 3]. Typically, PSCs that comprising 4 to 7% of total pancreatic mass are localized at the periacinar region of the exocrine pancreas. In normal condition, they are quiescent. Upon injury or inflammatory events, these PSCs are activated as they lose their fat-droplets and transform into myofibroblast-like phenotype that can be identified with the presence of α-smooth muscle actin (α-SMA or Acta2) [4, 5]. The formation of these fibrotic stress filaments subsequently elicits the cascade of tissue repairing mechanisms in response to pro-fibrotic and/or pro-inflammatory mediators such as transforming growth factor-beta (TGF-β) and tumor necrosis factor-alpha (TNF-α) generated against tissue injury [6, 7].

According to recent studies, TGF-β had been suggested to be the pivotal mediator involved in nearly all kinds of fibrotic conditions, for instance, hepatic fibrosis, pulmonary fibrosis and pancreatic fibrosis, and potently provoked the cascade of fibrotic events [8]. In fact, properties of stellate cells in the pancreas are similar to those present in other organs such as liver, kidney and lung. Once the stellate cells are activated, they produce massive extracellular matrix (ECM) proteins, namely fibronectin (FN1) and type I-collagen (COL I-1α) at the areas with active fibrogenesis for the purpose of tissue repairing as well as regeneration [4, 9]. In the exocrine pancreas, the production of ECM proteins in an imbalanced fashion causes scarring of the pancreatic parenchyma and leads to permanent morphological damages of the organ [10]. Progressive fibrosis probably results in anatomical anomalies, organ failure and even cancer [11]. The abolishment of overwhelmed production of ECM proteins and sustained activation of PSCs is therefore crucial to the treatment of fibrogenesis and the associated impairments of pancreatic functions.

The majority of pro-fibrotic mediators that initiate fibrosis-related signaling cascades converge at the activation of nuclear factor-kappaB (NF-κB), which is the central signal transducer for regulating cell proliferation, apoptosis, developmental processes and inflammatory responses [12, 13]. In most cells, NF-κB is present as a latent inactive complex when binding to its inhibitory subunit IκB-α in the cytoplasm. The nuclear translocation of NF-κB dimers (i.e. RelA/p50) indicates its activation [14]. A number of reports demonstrated that TGF-β is a potent inducer for the activation of NF-κB signaling [15, 16]. Previous works of our group showed that aberrant activation of NF-κB was observed in fibrotic and inflammatory conditions of the pancreas [17]. Sonic hedgehog (SHH) and its immediate effector glioma-associated oncogene (GLI1), which are the target genes of NF-κB, were accordingly elicited in response to tissue injury and exogenous stimulation of pro-inflammatory mediators including TGF-β and TNF-α [17, 18]. However, the molecular details of the tight control of NF-κB activation and up-regulation of SHH in fibrogenesis have yet clearly elucidated. In addition, the involvement of the phosphoinositide 3-kinase (PI3K)/serine-threonine kinase (AKT) signaling pathway in fibrogenesis in PSCs also deserves our detailed investigation.

Natural products have been shown to provide satisfactory effects on treating and preventing many human diseases over the past few decades. Eruberin A, also known as 2, 3-dehydroflavonoid glycoside (C24H28O9), can be extracted from the whole plant Pronephrium penangianum, a fern belongs to the Thelypteridaceae family. In fact, P. penangianum has been used as a folk medicine since ancient times in the Chinese population; for instance, the fronts of this fern are used for the treatment of irregular menstruation [19]. Previous phytochemical investigation demonstrated that several flavanol glycosides extracted from P. penangianum exerted significant antioxidant activities, particularly against diabetes-associated oxidative stress [20, 21]. The 2, 3-dehydroflavonoid glycoside, or eruberin A, had been reported to exhibit potent cytotoxic effects on cellular proliferation of L929 fibroblasts and HeLa cells.

KARGER
[22]. Nevertheless, studies on the anti-fibrotic actions and molecular mechanisms of this flavanol compound are very limited though eruberin A appears to possess a variety of pharmacological activities.

The immortalized LTC-14 cell line established by Sparmann G et al had been proved to retain the essential characteristics and morphological features of primary PSCs, and therefore this line served as an ideal in vitro platform for our study on the fibrogenesis-related mechanisms [23]. Besides, PANC-1 is a human PDAC line that possesses high levels of fibrotic markers and SHH components [18], was also employed in the current study. By utilizing these two cellular models, we aimed to elucidate the anti-fibrotic properties of eruberin A and the underlying mechanisms of its anti-fibrotic actions by means of various biochemical assays such as real-time polymerase chain reaction, Western blotting and immunofluorescent staining. Our results suggest that eruberin A suppresses the expression levels of fibrotic mediators and SHH components plausibly via down-regulating the PI3K/AKT/NF-κB signaling pathway. To this end, the cellular regulatory mechanism of fibrogenesis in PSCs is revealed.

Materials and Methods

Structural identification of eruberin A

Eruberin A was obtained as white needles and its molecular formula was established as C_{24}H_{28}O_{9} by time-of-flight (TOF) mass spectrometry (MS, m/z 483 [M+Na]+) and by the analysis of the carbon-13 nuclear magnetic resonance (^{13}C-NMR and DEPT) data. The proton (^{1}H)-NMR spectrum showed two singlet methyl characteristic signals at δ 2.60, and 2.07, a methoxy singlet signal at δ 3.83, an anomeric proton signal at δ 5.15 (d, J = 8.3 Hz), and four aromatic proton doublet signals at δ 7.43 (2H, d, J = 8.5 Hz) and 6.96 (2H, d, J = 8.5 Hz), suggesting a 1, 4-disubstituted ring B. The ^{13}C-NMR (DEPT) and heteronuclear single quantum coherence (HSQC) spectra revealed that the compound has one 1, 4-disubstituted phenyl group and one fully substituted phenyl group and two aromatic methyl groups in the aglycone. A substructure, -CH-CH_{2}-CH-, was also established through the spectral analysis of the ^{1}H-^{1}H correlation spectroscopy (COSY) data. The chemical structure of eruberin A was thus determined as a flavan-4-ol glycoside, which was firstly reported by Tanaka et al from their extraction of Pronephrium triphyllum Hollt [24]. Eruberin A used in the current present study was provided and authenticated by Dr. Y-G Chen from Yunnan Normal University, Kunming, China.

Cell line and culture condition

Rat PSC line LTC-14 [23], provided by Prof. Robert Jaster from University Hospital of Rostock, Germany and human PDAC line PANC-1, purchased from American Type Culture Collection, USA, were respectively maintained in Iscove’s Modified Dulbecco’s medium (IMDM, Gibco) and Dulbecco’s Modified Eagle medium (DMEM, Gibco), and routinely supplemented with 10% fetal bovine serum (FBS, Gibco) and 1% penicillin-streptomycin in a 5% CO_{2}, 95% air humidified atmosphere at 37°C. Recombinant TGF-β and TNF-α utilized in the in vitro experiments were purchased from Sigma-Aldrich.

Cell viability assay

LTC-14 cells were seeded in 96-well plates at a density of 8×10^3 cells/well and treated with eruberin A (0 to 200 μg/ml) for 24 hours (h). The cytotoxicity of eruberin A was evaluated in terms of mitochondrial metabolism by incubating the treated cells with 3-(4,5-cimethylthiazol-2-y1)-2,5-diphenyl tetrazolium bromide (MTT) reagent at 37°C for 3 h and then with isopropanol-hydrochloric acid at room temperature for 0.5 h. Spectrophotometric absorbance of the samples was measured at 570 nm using a microplate reader (Bio-rad).

Immunofluorescent staining

LTC-14 and PANC-1 cells were seeded at a density of 1×10^5 cells/well onto poly-L-lysine-coated cover slips in 24-well plates, pre-incubated with recombinant TGF-β (5 ng/ml) and treated with or without eruberin A (20 μg/ml) for 24 h. The cells were subsequently washed with phosphate buffered saline and...
fixed in ice-cold acetone:methanol (1:1, v/v) for 20 min. After rinsing, fixed cells were blocked with 3% bovine serum albumin, incubated with primary antibodies against α-SMA (Abcam) overnight at 4°C, and detected using FITC-conjugated anti-goat secondary antibody. Samples were then mounted with mounting medium containing 4',6-diamidino-2-phenylindole (DAPI, Sigma-Aldrich). Images were captured using the Nikon microscope and analyzed with the SPOT Advanced software.

**Real-time quantitative polymerase chain reaction (qPCR)**

Total RNA was extracted from LTC-14 and PANC-1 cells using TRizol reagent (Invitrogen) according to the manufacturer’s instruction and procedures described previously [25]. Two μg of RNA of each sample was transcribed into cDNA using PrimeScript RT master mix (Takara) in a total volume of 20 μl. The synthesized cDNA was applied to amplifications with rat- or human-specific primers for Tgf-β, Acta2, Col I-α1, Fn1, matrix metallopeptidase 2 (Mmp2) and Gapdh for 40 cycles in the ABI ViiA 7 real-time PCR system (Applied Biosystems) using 2X SYBR Green PCR Master Mix (Applied Biosystems). Expression of gene of interest of each sample was normalized to the endogenous control Gapdh. Fold changes were calculated using the comparative CT (2^{-ΔΔCT}) method. The primer sequences are listed in Table 1.

**Western blot analysis**

Protein from LTC-14 and PANC-1 cells was extracted in lysis buffers containing protease inhibitors on ice. For detection of NF-κB, nuclear fraction was used. Cell lysates were loaded, separated by 10 to 15% SDS-polyacrylamide gel electrophoresis and transferred onto PVDF membranes (Bio-rad) by wet electroblotting. The membranes were blocked with 5% non-fat dry milk in Tris-buffered saline containing 0.1% Tween 20 for 1 h at room temperature, incubated with anti-α-SMA (Abcam), FN1 (Novous), NF-κB p65 (Cell signaling), SHH, GLI1, β-ACTIN or LAMININ (Santa Cruz Biotechnology) antibodies overnight at 4°C, and subsequently incubated with horseradish peroxidase-conjugated secondary antibodies. Proteins were visualized by utilizing an ECL kit (GE Healthcare).

**Sirius Red and Fast Green staining**

The amounts of collagen and non-collagenous proteins in LTC-14 cells were determined using Sirius Red/Fast Green collagen staining kit (Chondrex Inc.) according to the manufacturer’s instruction. In brief, collagen proteins in LTC-14 cells were stained with Fast Green. With the addition of dye extraction solution, color was eluted from the cells. Absorbance at 540 nm and 640 nm were taken respectively for the amount of collagen and non-collagenous proteins. Data were expressed as a ratio of collagen proteins to total proteins.

**Depletion of Shh by RNA interference (RNAi) in LTC-14 cells**

Small interfering (siRNA) duplex specifically targeting rat Shh (sense: 5’-GCC GAU AUG GAG GGA AGA U-3’; anti-sense: 5’-AUC UUC CCU UCA UAU CCG C-3’) and a non-silencing control duplex (sense: 5’-GCC AUG UAA GGA GAG AGA U-3’; anti-sense: 5’-AUC UUC CCU UCA UAU CCG C-3’) were purchased from Invitrogen [17]. Twenty-four hours before transfection, LTC-14 cells were seeded in 24-well plates at a density of 1×10^5 cells/well in 0.5 ml complete culture medium without antibiotics. The siRNA oligos at 25 nM were delivered into the cells using Lipofectamine 2000 (Invitrogen). The silencing effects were examined by means of qPCR and Western blotting.
Statistical analysis
The statistical differences were determined using one-way analysis of variance (ANOVA) followed by Tukey's test as a post hoc test. All values are expressed as means ± standard derivation (S.D.). P value of < 0.05 is accepted as statistically significant.

Results

NMR analysis data
In comparison with the literature data, the natural compound used in our study was identified as the known flavan-4-ol glycoside, eruberin A (Fig. 1): $^1$H-NMR (CD$_3$OD, 500 MHz) δ 7.43 (2H, d, J = 8.5 Hz, H-2', 6'), 6.96 (2H, d, J = 8.5 Hz, H-3', 5'), 5.15 (1H, d, J = 8.3 Hz, H-1''), 5.10 (1H, m, H-4), 4.97 (1H, d, J = 4.3 Hz, H-2), 4.64 (1H, s, OH), 3.91, 3.68 (2H, m, H-6''), 3.83 (3H, s, OCH$_3$), 3.62 (1H, m, H-3''), 3.38 (1H, m, H-5''), 3.36 (1H, m, H-2''), 3.19 (1H, m, H-4''), 2.60 (3H, s, 6-CH$_3$), 2.32, 2.00 (2H, m, H-3), 2.07 (3H, s, 8-CH$_3$); $^{13}$C-NMR (CD$_3$OD, 125 MHz) δ 161.2 (s, C-4'), 156.4 (s, C-7), 153.2 (s, C-9), 151.7 (s, C-5), 135.2 (s, C-1'), 129.1 (d, C-2', 6'), 115.2 (d, C-3', 5'), 111.5 (s, C-6), 109.8 (s, C-8), 105.7 (s, C-10), 103.0 (d, C-1''), 79.3 (d, C-5''), 77.1 (d, C-3''), 76.3 (d, C-2''), 75.1 (d, C-2), 72.2 (d, C-4''), 67.5 (d, C-4), 63.4 (t, C-6''), 56.2 (q, OCH$_3$), 38.7 (t, C-3), 9.9 (q, 6-CH$_3$), 9.0 (q, 8-CH$_3$).

LTC-14 cells responded to pro-fibrotic agents
From the MTT cell viability assay, we found that recombinant TGF-β and TNF-α (1 to 20 ng/ml) slightly but not significantly accelerated or lowered the growth rate of LTC-14 cells (Fig. 2a). By means of qPCR, we noticed that the challenge of TGF-β concentration-dependently increased the transcript levels of Acta2, Tgf-β and Col I-α1; however, Mmp2, which encodes a major endopeptidase for modulating ECM degradation, was unaffected (Fig. 2b). The minimum effective stimulatory concentration of TGF-β in LTC-14 cells was determined to be 5 ng/ml. In order to validate the responsiveness, LTC-14 cells were also subjected to stimulation of TNF-α. From the qPCR result, we demonstrated that the challenge of TNF-α also led to an augmentation of Acta2 similar to the effect of TGF-β (Fig. 2c).

Cytotoxicity and anti-fibrotic effects of eruberin A in LTC-14 cells
The cytotoxicity of eruberin A was evaluated in terms of mitochondrial metabolism utilizing the MTT cell viability assay. LTC-14 cells were treated with eruberin A at various concentrations (0, 1, 10, 25, 50, 100 or 200 μg/ml) for 24 and 48 h. The results demonstrated that the growth rates of LTC-14 cells were decreased in response to the treatment of eruberin A in a dose-dependent manner. The LD$_{50}$ of eruberin A in LTC-14 cells was approximately 140 μg/ml (Fig. 3a). By means of qPCR, we showed that the mRNA levels of Acta2, Tgf-β, Col I-α1 and Fn1 in LTC-14 cells decreased with the increasing concentrations of eruberin A (Fig. 3b). As the LD$_{50}$ of eruberin A was roughly 140 μg/ml, the anti-fibrotic properties of eruberin A at concentrations of 20 μg/ml or lower in our experiments were not due to its cytotoxic effects.

Eruberin A suppressed TGF-β-induced elevation of fibrogenic mediators in pancreatic cells
Previous studies had revealed that TGF-β plays an important role in driving PSC activation and fibrotic events. In this study,
we examined whether eruberin A could inhibit TGF-β-induced fibrogenesis in LTC-14 cells. By means of qPCR, transcripts of fibrogenic genes including *Acta2*, *Tgf-β*, *Col I-α1* and *Fn1* were examined. As shown in Figures 4a-d, TGF-β remarkably elevated the mRNA levels
of *Acta2*, *Tgf-β*, *Col I-1α* and *Fn1* in LTC-14 cells, and eruberin A at 20 μg/ml significantly reversed all of the TGF-β-inducing effects. Similar suppressive effects of eruberin A treatment on expression of *TGF-β* and *COL I-1α* were also observed in PANC-1 cells (Fig. 4e-f). By means of Western blotting, protein levels of α-SMA and FN1 in LTC-14 cells were determined. As shown in Figure 5a, eruberin A counter-balanced the TGF-β-induced elevation of FN1 and α-SMA, and the trend in Western blotting was consistent with our qPCR results. On the other hand, the production of COL I-1α protein was evaluated using Sirius Red/Fast Green staining. The amount of Sirius Red-stained collagenous proteins was nearly doubled by the challenge of TGF-β at 5 ng/ml and such stimulation was repressed in the presence of eruberin A at 20 μg/ml (Fig. 5b). In addition, the levels of cytoplasmic α-SMA filaments in LTC-14 cells (Fig. 5c) and PANC-1 cells (Fig. 5d) were enhanced when incubated with TGF-β (5 ng/ml) and such enhancements were attenuated by eruberin A (20 μg/ml) as demonstrated by immunofluorescence. Taken together, our results revealed that eruberin A suppressed TGF-β-induced fibrogenic mediators in pancreatic cells.
Eruberin A down-regulated the activation of NF-κB and SHH signaling components

A number of reports had shown that NF-κB activation promotes fibrotic events, we therefore examined whether eruberin A inhibits this pivotal transcription factor in LTC-14 cells. Our Western blotting results demonstrated that the expression of the NF-κB p65 subunit in the nuclear fraction was attenuated by eruberin A, particularly at concentration of 20 μg/ml (Fig. 6a). Upon the stimulation of TGF-β (5 ng/ml), the expression levels of SHH and GLI1 were notably elevated. The addition of eruberin A (20 μg/ml) significantly suppressed SHH signaling pathway components in both LTC-14 (Fig. 6b) and PANC-1 cells (Fig. 6c). To further assess the involvement of SHH signaling pathway in fibrogenesis, Shh was depleted.
in LTC-14 cells by RNAi. Our qPCR results indicated that the expression levels of fibrotic filament *Acta2* and *Shh* were significantly decreased by the transfection of siRNA duplex (25 nM) specifically targeting rat *Shh* in LTC-14 cells, but not by the non-silencing control...
Eruberin A suppressed the activation of the PI3K/AKT pathway

The serine-threonine kinase AKT, a downstream effector of PI3K, is generally involved in cell survival, inflammatory and fibrotic cascades. In this study, we observed that AKT phosphorylation was increased after LTC-14 cells were treated with TGF-β (5 ng/ml). The application of eruberin A (20 μg/ml) notably inhibited the TGF-β-induced AKT phosphorylation (Fig. 7a). To examine whether the PI3K/AKT signaling pathway plays an important role in fibrogenesis, LY294002 (a PI3K inhibitor) and SC-66 (an allosteic AKT inhibitor) were applied. The Western blots showed that both LY294002 (10 μM) and SC-66 (10 μM) remarkably reduced the TGF-β-elevated levels of α-SMA and SHH in LTC-14 cells (Fig. 7b and 7c).
7b). This finding suggested that the PI3K/AKT signaling pathway is involved in pancreatic fibrogenesis. In addition, both LY294002 (10 μM) and SC-66 (10 μM) could also inhibit the TGF-β-induced nuclear translocation of NF-κB; thus, NF-κB modulation is associated with the PI3K/AKT pathway in the fibrotic responses of PSCs (Fig. 7c).

**Discussion**

Fibrogenesis is described as a dynamic process that leads to the formation of fibers or fibrous substances, and plausibly plays important roles in the progression of cancer. In the pancreas, fibrosis is commonly associated with the activation of PSCs in response to tissue injury or inflammation. Upon activation, PSCs produce massive ECM proteins namely FN1 and COL I-α1 for the purpose of tissue repairing. The overwhelmed deposition of ECM causes scarring of the parenchyma, which is replaced by connective tissues [4, 9]. The progressive fibrotic phenomenon indeed results in permanent morphological damages and subsequent anatomical anomalies, organ failure and cancer [1, 2]. Thus, targeting PSC activation is believed to be a novel therapeutic approach for treating and/or preventing pancreatic fibrosis, pancreatitis and PDAC.

The natural compound eruberin A is a 2,3-dehydroflavonoid glycoside isolated from the fern *P. penangianum*. The fronts of this fern have been used as a folk medicine for the management of irregular menstruation in the Chinese population for centuries [19]. In this study, we found that eruberin A actually possesses strong anti-fibrotic activities as it effectively suppressed the production of fibrotic filaments and ECM proteins in TGF-β-induced LTC-14 and PANC-1 cells while TGF-β had been reported in a number of in vitro and in vivo studies as one of the most potent pro-fibrotic inducers [8, 10]. In accordance with the earlier findings, commitment with the increased production of fibrotic mediators was the up-regulation of SHH signaling upon the administration of TGF-β [9, 10, 16]. The present study extends the previous work of our group on the positive role of SHH signaling in promoting the synthesis of fibrotic mediators as we reported that aberrant SHH
signaling had been observed in mice with cerulein-induced pancreatic fibrosis [17]. The reduction of ECM proteins and fibrotic filament α-SMA in LTC-14 cells by RNAi-depletion of Shh further elucidated the promoting role of SHH signaling in fibrogenesis. Conversely, the direct attenuation of expression levels of SHH and GLI1 uncovers the nature of eruberin A as a SHH inhibitor in PSCs. However, SHH is suggested as a downstream target gene of NF-κB in a number of cellular responses including fibrogenesis. A notable decreased nuclear expression of NF-κB, thus, was expectedly observed in LTC-14 cells treated with eruberin A. In line with previous findings, the chemical structures of flavanol glycosides and derivatives may be indicative of their pharmacological properties on modulating the activation of NF-κB. Chen J et al demonstrated that flavanol glycosides exert antioxidant activities and vascular protective potential in diabetic mice via the suppression of the NF-κB signaling pathway [21] whereas Dell’agli M and colleagues showed that catechins, compounds of flavanol derivatives, lowered MMP9 secretion via inhibiting NF-κB activation [26]. Apart from fibrosis and pancreatitis, SHH signaling also plays important roles in some intercalating pathologies such as pancreatic tumorgenesis, metastasis and invasion [27, 28]. In this regard, a SHH signaling-oriented therapeutic approach may serve as an effective remedy for pancreatitis, fibrosis as well as PDAC.

A large body of reports demonstrated that PI3K/AKT signaling pathway was highly associated with cell proliferation, inflammatory responses, tumorgenesis and metastasis. For instance, increased AKT phosphorylation enhanced proliferation and invasiveness of human pancreatic cancer cells [29] and promoted activation of hepatic stellate cells [30] whereas aberrant activation of PI3K/AKT has been observed in patients with advanced enteropancreatic neuroendocrine tumors [31, 32]. Some recent reports suggested that the transcription factor NF-κB was negatively modulated in response to the down-regulation of the PI3K/AKT pathway [12, 33, 34]. In this study, upon the application of LY249002 (a PI3K inhibitor) or SC-66 (an AKT inhibitor), the expression levels of p-AKT and nuclear NF-κB p65 in LTC-14 cells were remarkably decreased followed by a loss of fibrotic filament α-SMA and ECM proteins. Our results support the previous findings that PI3K/AKT signaling pathway plays a role in fibrogenesis and modulates the transcription factor NF-κB. Most importantly, the activation of both p-AKT and NF-κB in LTC-14 cells was significantly inhibited by the treatment of eruberin A. Collectively, we deduced that the anti-fibrotic effects of eruberin A involved the suppression of the PI3K/AKT/NF-κB pathway (Fig. 8).
In conclusion, the current study demonstrated that eruberin A suppressed the production of ECM proteins FN1 and COL1-α1 and the formation of fibrotic filament α-SMA \textit{in vitro} by modulating SHH signaling components, by which an attenuation of the PI3K/AKT/NF-κB pathway was involved. Thus, the cellular regulatory mechanisms of fibrotic mediators in PSCs and PDAC cells have been partially revealed.

**Disclosure Statement**

The authors filed a US non-provisional patent application titled "Use of a flavanol glycoside for suppressing activation of stellate cells" on May 22, 2013 with an application number US 13/899,713.

**Acknowledgement**

Eruberin A was kindly provided by Dr. Y-G Chen from Yunnan Normal University, Kunming, China. We are grateful to Prof. R Jaster from University Hospital of Rostock, Rostock, Germany for providing us the LTC-14 cell line. This work was supported by the National Natural Science Foundation of China (Young Scientist Project #81400666) and Hong Kong Baptist University (Interdisciplinary Research Matching Scheme #RC-IRMS/12-13/03).
