Abstract

Building on a recent paper \[6\], here we argue that the combinatorics of matroids is intimately related to the geometry and topology of toric hyperkähler varieties. We show that just like toric varieties occupy a central role in Stanley’s proof for the necessity of McMullen’s conjecture (or \(g\)-inequalities) about the classification of face vectors of simplicial polytopes, the topology of toric hyperkähler varieties leads to new restrictions on face vectors of matroid complexes. Namely in this paper we will give two proofs that the injectivity part of the Hard Lefschetz theorem survives for toric hyperkähler varieties. We explain how this implies the \(g\)-inequalities for rationally representable matroids. We show how the geometrical intuition in the first proof, coupled with results of Chari \[2\], leads to a proof of the \(g\)-inequalities for general matroid complexes, which is a recent result of Swartz \[18\]. The geometrical idea in the second proof will show that a pure \(O\)-sequence should satisfy the \(g\)-inequalities, thus showing that our result is in fact a consequence of a long-standing conjecture of Stanley.

1 Introduction

McMullen \[12\] conjectured in 1971 that the face vector\(^1\) \((f_0, \ldots, f_{k-1})\) of a \(k\)-dimensional simplicial polytope \(P \subset \mathbb{R}^k\) should satisfy, what we call, \(g\)-inequalities:

\[
g_i \geq 0, \text{ for } 1 \leq i \leq \lfloor \frac{k}{2} \rfloor,
\]
and, if one writes

\[
g_i = \binom{n_i}{i} + \binom{n_{i-1}}{i-1} + \cdots + \binom{n_1}{i}
\]
with \(n_i > n_{i-1} > \cdots > n_r \geq r \geq 1\), then

\[
g_{i+1} \leq \binom{n_i+1}{i+1} + \binom{n_{i-1}+1}{i+1} + \cdots + \binom{n_1+1}{i+1}
\]
for \(1 \leq i < \lfloor \frac{k}{2} \rfloor\),

where

\[
g_i = h_i - h_{i-1}
\]

\(^1f_i\) is the number of \(i\)-dimensional faces
and
\[ h_i = \sum_{j=1}^{k} (-1)^{i-j} \binom{j}{i} f_{k-j-i}. \]  

Stanley [13] in 1980 proved this conjecture using toric varieties. In a nutshell his argument goes as follows. First one perturbs the vertices of \( P \) a little bit so that \( P \) becomes a rational polytope. Because \( P \) is simplicial this does not change the face vector of \( P \). The next step is to take the corresponding \( k \)-dimensional toric orbifold \( X(\Delta_P) \), where \( \Delta_P \) is the fan of cones over the faces of \( P \). It is a well-known fact (see e.g. [5]) that the \( i \)th \( h \)-number \( h_i = b_{2i}(X(\Delta_P)) \) agrees with the \( 2i \)th Betti number of \( X(\Delta_P) \). Now \( X(\Delta_P) \) has an ample class \( \omega \in H^2(X(\Delta_P), \mathbb{C}) \), which induces a map
\[ L : H^*(X(\Delta_P), \mathbb{C}) \rightarrow H^*(X(\Delta_P), \mathbb{C}), \]
by multiplication with \( \omega \). Using the injectivity part of the Hard Lefschetz theorem (see e.g. [3]), which implies that \( L \) is an injection below degree \( k \), we get that the degree \( 2i \)th part of the graded algebra \( H^*(X(\Delta_P), \mathbb{C})/(\ker(L)) \) has dimension
\[ \dim(H^{2i}(X(\Delta_P), \mathbb{C})/(\ker(L))) = h_i - h_{i-1} = g_i \]
for \( 2i < k \). Since \( H^*(X(\Delta_P), \mathbb{C}) \) is generated by \( H^2(X(\Delta_P), \mathbb{C}) \) we also get that the algebra \( H^*(X(\Delta_P), \mathbb{C})/(\ker(L)) \) is generated in degree 2. Now, using (3), a well-known theorem of Macaulay (see e.g. [17] Theorem II.2.3) proves the \( g \)-inequalities [1]. See [5] or [17] for more details.

Our starting point is the observation [6] Corollary 1.2] that the \( h \)-vectors of a rationally representable matroid \( M_B \) agree \( h_i(M_B) = b_{2i}(Y(A, \theta)) \) with the Betti numbers of a toric hyperkähler variety \( Y(A, \theta) \), for a generic choice of \( \theta \), where the toric hyperkähler variety can be considered as a quaternionic analogue of a toric variety. Therefore any restriction on the cohomology of a toric hyperkähler variety will yield restrictions on the face vectors of rationally representable matroid complexes and vice versa any known restriction on the face vectors of (rationally representable) matroids yields cohomological restrictions on toric hyperkähler varieties. This two-way relationship between these two seemingly unrelated subjects, hyperkähler geometry on one hand and combinatorics of matroids on the other, is what we call “Quaternionic geometry of matroids”. A relationship of this flavor is exploited in a recent paper by Swartz and the author [7]. There the combinatorics of affine hyperplane arrangements yields the existence of many \( L^2 \) harmonic forms on the corresponding toric hyperkähler manifold, in harmony with conjectures by physicists in string theory. For details see the paper [7].

In the present paper our purpose is to use intuition arising from the study of the geometry of toric hyperkähler varieties to prove results in the combinatorics of matroids. Namely we will proceed as follows: In the next Section 2 and Section 3 we recall some basic notations and results from [17] and from [6]. Then we go on and in Section 4 give two different proofs for the injectivity part of the Hard Lefschetz theorem for toric hyperkähler varieties. The second one is basically taken from [17] Theorem 7.4], while the first proof could be easily generalized for other similar hyperkähler manifolds, like for example Nakajima’s quiver varieties [14] or Hitchin’s moduli of Higgs bundles [9]. In Section 5 then we explain how the geometric idea in the first proof can be generalized for any matroid complexes, a result recently proven by Swartz in [18]. What we show is that the geometrical structure for the first proof is provided for general matroids by Chari’s decomposition theorem [2]. In fact this proof is similar to Swartz’s original proof in [18]. We
conclude our paper by showing that the geometric structure which yielded the second proof of the injective Hard Lefschetz theorem is present for pure $O$-sequences. This way we find that the $g$-inequalities we proved in the previous section are in fact a consequence of a long standing conjecture of Stanley [16]. This last result is a strengthening of a result of Hibi in [8].

Acknowledgement. This paper grew out from a project started with Bernd Sturmfels in [6]. Conversations with Edward Swartz were also useful. Financial support was provided by a Miller Research Fellowship at the University of California at Berkeley, and by NSF grants DMS-0072675 and DMS-0305505.

2 Simplicial and matroid complexes

We collect here some basic definitions and results on simplicial complexes and in particular matroid complexes from [17].

A simplicial complex $\Sigma$ on a finite set $V = \{1, \ldots, n\}$ is a set of subsets of $V$, i.e. $\Sigma \subset 2^V$, such that $\{x\} \in \Sigma$ for any $x \in V$ and $F \in \Sigma$ and $F' \subset F$ implies $F' \in \Sigma$. We call $F \in \Sigma$ a face of $\Sigma$, the dimension of the face is one less than its size. The dimension of $\Sigma$ is then the maximum dimension of its faces, while its rank is 1 more. A facet is a face of maximal dimension. A simplicial complex is called pure if its maximal faces are all facets. The $f$-vector of a rank-$k$ simplicial complex is $(f_0, f_1, \ldots, f_{k-1})$, where $f_i$ is the number of $i$-dimensional faces in $\Sigma$. The $h$-vector of the simplicial complex is $(h_0, \ldots, h_k)$ given by [2].

Define the Stanley-Raisner ring of a rank-$k$ simplicial complex $\Sigma$ as a graded ring given by:

$$C[\Sigma] = C[x_1, \ldots, x_n]/\langle x_F \mid \prod_{i \in F} x_i | F \not\in \Sigma \rangle.$$ 

All our simplicial complexes in this paper will be Cohen-Macaulay, which will imply that we will always have a linear system of operators or l.s.o.p for short, which is a sequence $(\theta) = (\theta_1, \ldots, \theta_k)$ of linear combinations of the $x_i$, such that the graded ring

$$C[\Sigma]/(\theta) := C[\Sigma]/(\theta_1 C[\Sigma] + \cdots + \theta_k C[\Sigma])$$

is finite dimensional as a vector space over $C$ and that the $h$-numbers $h_i(\Sigma) = (C[\Sigma]/(\theta))_i$ agree with the dimension of the corresponding graded piece of $C[\Sigma]/(\theta)$.

We will use the following operation on simplicial complexes in Section 3. Given two simplicial complexes $\Sigma$ with vertex set $V$ and $\Theta$ with vertex set $U$ we define their poset-theoretic product $\Sigma \times \Theta$ as a simplicial complex with vertex set $U \cup V$ and all faces of the form $F \cup F'$ where $F \in \Sigma$ and $F' \in \Theta$. The poset-theoretic product has the advantage that it behaves nicely after taking the corresponding Stanley-Raisner rings: $C[\Sigma \times \Theta] \cong C[\Sigma] \otimes C[\Theta]$.

For examples of (Cohen-Macaulay) simplicial complexes we mention the boundary complex of a simplicial convex polytope, which was mentioned in the introduction. Another class for interest for us are matroid complexes or simply just matroids. A matroid complex $M$ is a simplicial complex on a vertex set $V$ such that for every $W \subset V$ the induced subcomplex $M_W = \{ F \in M : F \subset W \}$ is pure. The rank of the matroid is 1 more than its dimension. A vertex $i \in V$ is a coloop of $M$ if $M_{V \setminus i}$ has rank smaller than the rank of $M$.

The motivating example of a matroid complex $M_B$ on vertex set $V = \{1, \ldots, n\}$ is obtained from a vector configuration $B = (b_1, \ldots, b_n) \in \mathbb{K}^k$ in a $k$-dimensional vector space over a field $\mathbb{K}$,
defined by $F \in \mathcal{M}$ iff $\{b_i\}_{i \in F}$ is linearly independent. Such a matroid is called representable over $\mathbb{K}$. For example, if $\mathbb{K} = \mathbb{Q}$ then we call the matroid $\mathcal{M}$ rationally representable.

For more details on these definitions consult [17], the poset-theoretic product was used in [2].

3 Toric hyperkähler varieties

Here we collect notation and terminology from [6] which we will need in the present paper. For more details see [6].

Let $A = [a_1, \ldots, a_n]$ be a $d \times n$-integer matrix whose $d \times d$-minors are relatively prime. We choose an $n \times (n-d)$-matrix $B = [b_1, \ldots, b_n]^T$ which makes the following sequence exact:

$$0 \rightarrow \mathbb{Z}^{n-d} \xrightarrow{B} \mathbb{Z}^n \xrightarrow{A} \mathbb{Z}^d \rightarrow 0.$$

Taking $\theta \in \mathbb{N}A$, where $A := \{a_1, \ldots, a_n\}$ is a vector configuration in $\mathbb{Z}^d$, [6] constructs a quasi-projective variety $Y(A, \theta)$ (which sometimes we abbreviate as $Y$), called a toric hyperkähler variety. (This construction is an algebraic geometric version of the original construction of Bielawski and Dancer in [1].) By [17, Proposition 6.2] if $\theta \in \mathbb{N}A$ is generic $Y(A, \theta)$ is an orbifold, while if, in addition, $A$ is unimodular then $Y(A, \theta)$ is a smooth variety.

The topology of $Y(A, \theta)$ is governed by an affine hyperplane arrangement denoted by $\mathcal{H}(B, \psi)$ of $n$ planes in $\mathbb{R}^{n-d}$. For example a key result in [17, Corollary 6.6] claims that the $h$-numbers of the matroid of the vector configuration $B = \{b_1, \ldots, b_n\}$ agree with the Betti numbers of $Y$:

$$h_i(\mathcal{M}_B) = b_{2i}(Y(A, \theta)).$$

In the next section we will make use of a projective subvariety $C(A, \theta)$ of $Y(A, \theta)$, which is called the core of $Y(A, \theta)$. It is a reducible variety whose components are projective toric varieties, corresponding to top dimensional bounded regions in $\mathcal{H}(B, \psi)$. If the matroid of $B$ is coloop-free than the core is a middle and pure dimensional projective subvariety of $Y(A, \theta)$.

Finally we need to mention a result from [4]. They construct and study a certain residual $U(1)$-action on $Y(A, \theta)$, which comes from an algebraic $\mathbb{C}^\times$-action. It follows from their results that, when $B$ is coloop-free, one can always choose such a circle action, which makes $Y(A, \theta)$, what we call, a hyper-compact hyperkähler manifold. It means that the $U(1)$-action is Hamiltonian with proper moment map with a minimum, and also that the holomorphic symplectic form $\omega_C$ is of homogeneity 1, meaning that for $\lambda \in \mathbb{C}^\times$

$$\lambda^* \omega = \lambda \omega. \quad (4)$$

For further results about the topology and geometry of toric hyperkähler varieties consult the papers [1, 4, 6, 7] and [10].

4 Injective Hard Lefschetz for hyperkähler manifolds

We are now ready to give two proofs of the following

**Theorem 4.1** For a smooth toric hyperkähler variety $Y(A, \theta)$ of real dimension $4n - 4d = 4k$, such that $B$ is coloop-free, we have that

$$L^{k-2i} : H^{2i}(Y, \mathbb{C}) \rightarrow H^{2k-2i}(Y, \mathbb{C})$$

$$L^{k-2i}(\alpha) = \alpha \wedge \omega^{k-2i}. \quad (5)$$
is injective if $2i < k$, where $\omega = [\omega_I]$ is the cohomology class of the Kähler form corresponding to the complex structure $I$.

Just like in Stanley’s proof of the McMullen conjecture, we also have the following numerical consequences:

**Corollary 4.2** The $h$-vector $(h_1(M), \ldots, h_k(M))$ of a coloop-free and rank $k$ matroid $M$, which is (unimodularly and) rationally representable, satisfies

$$h_i(M) \leq h_j(M),$$

for $i \leq j \leq k - 1$ and the $g$-inequalities [4].

**Proof of Corollary.** Let the (unimodular) vector configuration $B = \{b_1, \ldots, b_n\} \in \mathbb{Z}^k \subset \mathbb{Q}^k$ represent the matroid $M$. Choosing a Gale dual configuration $A = (a_1, \ldots, a_n) \in \mathbb{Z}^d$ and a generic $\theta \in \mathbb{N}A$, we can construct a smooth toric hyperkähler variety $Y(A, \theta)$, whose Betti numbers agree with the $h$-numbers of $M$. Now Theorem 4.1 immediately implies (4). From Theorem 4.1 we can also deduce (4) exactly as in Stanley’s argument for simplicial convex polytopes. See the introduction or for more details [17, Theorem III.1.1].

**Proof 1 of Theorem 4.1.** As explained above we have a $\mathbb{C}^\times$-action on $Y := Y(A, \theta)$, for which the corresponding $U(1) \subset \mathbb{C}^\times$-action is hyper-compact. Recall that this means that it is Hamiltonian with a proper moment $\mu_B : Y \to \mathbb{R}$ map with respect to $\omega$, and for which the holomorphic symplectic form $\omega_C$ is of homogeneity $1$ meaning (4). Suppose that the fixed point set of the circle action has $f$ components, which are denoted by $F_1, \ldots, F_f$. The numbering is such that $\mu_C(F_m) > \mu_C(F_l)$ implies $m > l$. Now we define the Bialynicki-Birula stratification of $Y$ with respect to our $\mathbb{C}^\times$-action. Namely define $U_m = \{p \in Y | \lim_{\lambda \to 0} \lambda p \in F_m\}$, which is an affine bundle over $F_m$. Moreover we let $U_{\leq m} = \cup_{j \leq m} U_j$ and $U_{\leq m} = \cup_{j < m} U_j$, which are open subvarieties of $Y$. Because the moment map $\mu_B$ is proper it follows that $U_{\leq f} = Y$, i.e. that we get this way a stratification of $Y$. Finally we denote by $N_m$ the negative normal bundle of $F_m$. Because the holomorphic symplectic form is of homogeneity $1$ with respect to our $\mathbb{C}^\times$-action, it follows (cf. [13, Proposition 7.1]) that

$$\text{rank}_C(N_m) + \dim_C(F_m) = \frac{1}{2} \dim_C Y = k. \quad (7)$$

By induction on $m$ we prove that the map $L^{k-2i}$ in (4) when restricted to $U_{\leq m}$ is injective for $2i < k$. For $m = 1$ the statement is clear because by (4) $U_1 = T^*F_1$ thus $\dim_C(F_1) = k$ and the statement follows from the traditional Hard Lefschetz theorem for the compact Kähler manifold $F_1$. Now suppose we have the required injectivity of the map $L^{k-2i}$ on $U_{\leq m}$. Then consider the decomposition $U_{\leq m} = U_{\leq m} \cup U_m$. From this decomposition, using the Thom isomorphism

$$H^{2i}(U_{\leq m}, U_{<m}; \mathbb{C}) \cong H^{2i-2nm}(U_m, \mathbb{C}), \quad (8)$$

we get the cohomology exact sequence:

$$0 \to H^{2i-2nm}(U_m, \mathbb{C}) \to H^{2i}(U_{\leq m}, \mathbb{C}) \to H^{2i}(U_{<m}, \mathbb{C}) \to 0,$$
where \( n_m = \text{rank}_C(N_m) \), \( \tau \) is the Gysin map and \( r \) is the natural restriction map on cohomology. Now suppose \( 2i < k \) and \( 0 \neq \alpha \in H^{2i}(U_{\leq m}, \mathbb{C}) \). If \( r(\alpha) \neq 0 \), then by induction we can deduce that \( L^{k-2i}(\alpha) \neq 0 \). However if \( r(\alpha) = 0 \), then there is a \( \beta \in H^{2i-2n_m}(U_m, \mathbb{C}) \) such that \( \tau(\beta) = \alpha \). However \( U_m \) is homotopy equivalent with the smooth compact Kähler manifold \( F_m \) and \( \omega|_{F_m} \) is a Kähler class. If we denote \( f_m = \dim_C F_m \), then the Hard Lefschetz theorem for \( F_m \) yields that \( 0 \neq \beta \wedge \omega^{f_m-2(i-n_m)}|_{F_m} = \beta \wedge \omega^{k-2i+n_m}|_{F_m} \), because \( f_m + n_m = k \) by (7). Because \( \tau \) is injective we get that \( \tau(\beta \wedge \omega^{k-2i}|_{F_m}) = \alpha \wedge \omega^{k-2i}|_{U_{\leq m}} \neq 0 \).

The result follows. \( \square \)

**Corollary 4.3** For a hyper-compact hyperkähler manifold \( M \) (such as e.g. toric hyperkähler varieties or Nakajima’s quiver varieties [17] or moduli spaces of Higgs bundles [14]) we have that

\[
L^{k-2i} : H^{2i}(M, \mathbb{C}) \to H^{2k-2i}(M, \mathbb{C})
\]

is injective if \( 2i < k \), where \( \omega = [\omega_I] \) is the class of the Kähler form corresponding to the complex structure \( I \).

We now recall our original proof of Theorem 4.1 from [6] Theorem 7.4] in the smooth case because we will use the idea in the final section.

**Proof 2 of Theorem 4.1** Let \( X_1, \ldots, X_r \) denote the irreducible components of the core of \( Y \). Let \( \phi_i : H^\ast(Y, \mathbb{C}) \to H^\ast(X_i, \mathbb{C}) \) denote the natural restrictions. The heart of the proof of [6] Theorem 7.4] is then that

\[
\ker(\phi_1) \cap \ker(\phi_2) \cap \ldots \cap \ker(\phi_r) = \{0\}. \tag{9}
\]

In [6] we presented two proofs of this fact. One [6] Proposition 3.4] was a more general result for semi-projective toric orbifolds and the proof goes similarly to our first Proof 1 of Theorem 4.1 above, i.e. uses Morse theory type considerations with induction. It turns out that [6] Proposition 3.4] is equivalent with the fact that the bounded complex of the polytope (or in our case the bounded complex of the affine hyperplane arrangement \( \mathcal{H}(B, \psi) \)) is always contractible. The second proof was given after equation (34) of [5], which showed that [5] is in fact equivalent with Stanley’s result [17] Proposition III.3.2] that the Stanley-Raisner ring of a matroid is level.

Now we proceed as follows. For \( 2i < k \) take \( \alpha \in H^{2i}(Y, \mathbb{C}) \). Then because of (7) we have a \( j \) so that \( \phi_j(\alpha) \in H^{2i}(X_j, \mathbb{C}) \) is nonzero. But the traditional hard Lefschetz theorem for the smooth compact Kähler manifold \( X_j \) implies that \( \phi_j(\alpha \wedge \omega^{k-2i}) \neq 0 \).

The result follows. \( \square \)

**Remark.** 1. [6] Theorem 7.4] proves the same result, in the way sketched above, for a rationally representable matroid, i.e. for toric hyperkähler orbifolds, not just for smooth toric hyperkähler varieties. Here we restricted our attention to the smooth case, because the other Proof 1 only works in this case. The reason is that [17] could be false in the orbifold case.

2. Proof 1 works for any hyper-compact hyperkähler manifold, however an extension of Proof 2 in the general case is not immediate. Indeed the equivalent of (9) (perhaps in intersection cohomology) is not known for a general hyper-compact hyperkähler manifold.

3. Another consequence of [13], explained in [6] Section 7], is that one can present the cohomology ring of \( Y \), in terms of cogenerator polynomials corresponding to the \( X_i \), the components
of the core. Indeed this algebraic presentation is rather similar to a presentation of a pure $O$-sequence, the only difference will be that we replace the cogenerator polynomials by monomials. This similarity will lead to the proof of Theorem 6.2 below.

5 Proof of the $g$-inequalities for matroid complexes

In this section we will use the geometrical idea from our first proof of Theorem 4.1 to prove the following generalization:

Theorem 5.1 The $h$-vector $(h_1(\mathcal{M}), \ldots, h_k(\mathcal{M}))$ of a coloop-free and rank $k$ matroid $\mathcal{M}$ satisfies (6) and the $g$-inequalities (7).

Remark. This was first proven by Swartz [18], by using an algebraic version of Chari’s [2] decomposition theorem of matroids. Here we will show, that [2] is in fact gives us the geometrical structure for a general matroid so that we can repeat our Morse theory type first proof of Theorem 4.1. In fact this proof is similar to Swartz’s original proof.

Proof: So let us first recall Chari’s result [2, Theorem 3]:

Theorem 5.2 (Chari) A coloop-free matroid complex is PS-decomposable. A pure rank-$k$ simplicial complex $\Sigma$ on a vertex set $\{1, \ldots, n\}$ is PS-decomposable if it can be covered by pure rank-$k$ simplicial subcomplexes $\Sigma = \bigcup_{i=1}^{m} \Sigma_i$, such that

- $\Sigma_1$ is the poset-theoretic product of boundaries of simplices (a PS-$k$-sphere in the terminology of [2]), while for each $i = 2, \ldots, m$, $\Sigma_i$ is the poset-theoretic product of a simplex and a PS-sphere (called a PS-ball in [2]), and

- For $i \geq 2$, $\Sigma_i \cap \left( \bigcup_{j=1}^{i-1} \Sigma_j \right) = \partial \Sigma_i$, where $\partial \Sigma_i$ denotes the pure rank-$(k-1)$ simplicial complex (which is just a PS-sphere in this case) whose facets are the rank-$(k-1)$ faces of $\Sigma_i$ that are contained in only one facet of $\Sigma_i$.

We will show that Theorem 5.1 holds for PS-decomposable simplicial complexes, a result which was also mentioned by Swartz in [18]. We will see that this PS-ear-decomposition is in fact a very good combinatorial analogue of the Morse stratification of $Y$ (or rather its Lagrangian core) used in Proof 1 of Theorem 4.1.

We first make a

Definition 5.3 Let $R$ be a ring and $M$ be a graded $R$-module. Then we say that $M$ satisfies injective hard Lefschetz (IHL for short) around degree $k/2$ for $\omega \in R_1$ if the map

$$L^{k-2i} : M_i \to M_{k-i}$$

is injective for $0 < i \leq k/2$.

We will proceed by induction on $m$ to show that

there is an l.s.o.p $(\theta_1, \ldots, \theta_k)$ so that the graded ring $\mathbb{C}[\Sigma]/(\theta)$ satisfies IHL around $k/2$ with $\omega = \sum_i x_i$. (10)
When $m = 1$, then $\Sigma$ is just a poset-theoretic product of boundaries of simplices and, therefore $\mathbb{C}[\Sigma]$ can be thought of as the torus equivariant cohomology ring of a product of projective spaces, while an l.s.o.p. $(\theta)$ can be chosen so that $\mathbb{C}[\Sigma]/(\theta)$ is just the cohomology ring of the product of projective spaces, then $\omega = \sum x_i$ is just a Kähler class, so the classical Hard Lefschetz theorem proves (10).

Now suppose we know our statement for $m - 1$ and consider a pure rank-$k$ simplicial complex with a PS-ear-decomposition. Let us denote $\Sigma_{<m} = \cup_{j=1}^{m-1} \Sigma_j$. Consider the natural surjective map $\mathbb{C}[\Sigma] \to \mathbb{C}[\Sigma_{<m}]$. We think of the kernel of this map as a graded $\mathbb{C}[x_1, \ldots, x_n]$-module and denote it by $\mathbb{C}[\Sigma, \Sigma_{<m}]$. So we have the following exact sequence of graded $\mathbb{C}[x_1, \ldots, x_n]$-modules:

$$0 \to \mathbb{C}[\Sigma, \Sigma_{<m}] \to \mathbb{C}[\Sigma] \to \mathbb{C}[\Sigma_{<m}] \to 0.$$  

We now claim that we can find an l.s.o.p $(\theta) = (\theta_1, \ldots, \theta_k)$ for $\mathbb{C}[\Sigma]$ such that in both graded $\mathbb{C}[x_1, \ldots, x_n]$-modules $\mathbb{C}[\Sigma_{<m}]/(\theta)$ and $\mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta)$ the IHL for $\omega$ is satisfied around degree $k/2$.

By induction we know that the set of $(\theta)$ which is an l.s.o.p. for $\mathbb{C}[\Sigma_{<m}]$ and $\mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta)$ satisfies IHL for $\omega$ is non-empty and clearly Zariski open in $\mathbb{C}^{nk}$. Consequently the set of $(\theta)$ which is an l.s.o.p for $\mathbb{C}[\Sigma]$ and $\mathbb{C}[\Sigma_{<m}]/(\theta)$ satisfies IHL for $\omega$ is non-empty and Zariski open. It is also clear that the set of $(\theta)$ which is an l.s.o.p for $\mathbb{C}[\Sigma]$ and $\mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta)$ satisfies IHL around degree $k/2$ for $\omega$ is Zariski open. We now prove that it is in fact non-empty. Take the natural map $\mathbb{C}[\Sigma_m] \to \mathbb{C}[\partial \Sigma_m]$ and denote by $\mathbb{C}[\Sigma_m, \partial \Sigma_m]$ the kernel. We think of this kernel as a $\mathbb{C}[x_1, \ldots, x_n]$-module by letting the variables $x_j$ which correspond to vertices not in $\Sigma_m$ acting trivially. Then it is easy to see that $\mathbb{C}[\Sigma_m, \partial \Sigma_m]$ and $\mathbb{C}[\Sigma, \Sigma_{<m}]$ are isomorphic as graded $\mathbb{C}[x_1, \ldots, x_n]$-modules (this is the analogue of excision in cohomology). But $\Sigma_m = \Delta \times \Phi$ is a poset-theoretic product of a $k$-simplex $\Delta$ with a poset-theoretic product of boundary of simplices $\Phi$. Now it is clear that

$$\mathbb{C}[\Sigma_m, \partial \Sigma_m] \cong \mathbb{C}[\Phi] \otimes \mathbb{C}[\Delta, \partial \Delta]$$

as graded $\mathbb{C}[x_1, \ldots, x_n]$-modules (this corresponds to the Thom isomorphism \blacklozenge in cohomology). If $x_1, \ldots, x_l$ correspond to the vertices of $\Delta$ then $\mathbb{C}[\Delta, \partial \Delta]$ is just a free $\mathbb{C}[x_1, \ldots, x_l]$-module generated by a degree $k$ element $x_1x_2 \ldots x_l$ (which is the analogue of the Thom class).

First we note that the set of $(\theta) = (\theta_1, \ldots, \theta_k) \in (\mathbb{C}[\Sigma])^k = \mathbb{C}^{nk}$ for which

$$\mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta) := \mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta_1 \mathbb{C}[\Sigma, \Sigma_{<m}] + \cdots + \theta_k \mathbb{C}[\Sigma, \Sigma_{<m}])$$

satisfies IHL around degree $k/2$ for $\omega = \sum_{i=1}^n x_i$ is clearly Zariski open in $\mathbb{C}^{nk}$. Now we show that it is non-empty. Take $(\theta) = (x_1, \ldots, x_l, \theta_{l+1}, \ldots, \theta_k)$, so that $(\theta_{l+1}, \ldots, \theta_k)$ is an l.s.o.p for $\mathbb{C}[\Phi]$ and $\mathbb{C}[\Phi]/(\theta_{l+1}, \ldots, \theta_k)$ satisfies IHL around $(k-l)/2$ with $\omega = \sum x_i$.

For this choice we have

$$\mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta) = x_1x_2 \ldots x_l \mathbb{C}[\Phi]/(\theta_{l+1}, \ldots, \theta_k),$$

and so IHL for $\mathbb{C}[\Phi]/(\theta_{l+1}, \ldots, \theta_k)$ around degree $(k-l)/2$ implies IHL for $\mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta)$ around degree $k/2$ with $\omega = \sum x_i$.

As the intersection of non-empty Zariski subsets of $\mathbb{C}^{nk}$ are non-empty we can choose a $(\theta) = (\theta_1, \ldots, \theta_k)$, which is an l.s.o.p for $\mathbb{C}[\Sigma]$ and $\mathbb{C}[\Sigma_{<m}]$ and for which both $\mathbb{C}[\Sigma_{<m}]/(\theta)$ and $\mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta)$ satisfies IHL around $k/2$ with $\omega = \sum x_i$. Now using the short exact sequence:

$$0 \to \mathbb{C}[\Sigma, \Sigma_{<m}]/(\theta) \to \mathbb{C}[\Sigma]/(\theta) \to \mathbb{C}[\Sigma_{<m}]/(\theta) \to 0,$$
we can repeat the argument of Proof 1 of Theorem 4.1 to get that $C[\Sigma]/(\theta)$ satisfies IHL around $k/2$ with $\omega = \sum x_i$.

Because a PS-decomposable simplicial complex $\Sigma$ is shellable (see [2, Proposition 5]), and so Cohen-Macaulay, we have that $h_i(\Sigma) = \dim_C((C[\Sigma]/(\theta))_i)$ and so Theorem 5.1 follows. □

Remark. Because we have Hard Lefschetz theorem for boundary complexes of simplicial convex polytopes the above proof would have worked equally well for simplicial complexes with a decomposition just like PS-ear-decomposition above, but changing $PS$-spheres, in the definition, with boundary complexes of simplicial convex polytopes. For a unimodularly and rationally representable matroid such a presentation always arises naturally. Namely we can consider the Morse stratification (for details on this see [4]) of a hyper-compact $U(1)$-action on the bounded complex of a generic hyperplane arrangement, representing our given matroid. In this case the above combinatorial proof of Theorem 5.1 would essentially agree with Proof 1 of Theorem 4.1.

6 Proof of the $g$-inequalities for pure $O$-sequences

First a definition:

**Definition 6.1** A sequence of non-negative integers $(h_1, h_2, \ldots, h_k)$ is called a pure $O$-sequence, if $h_k > 0$ and there exists monomials $m_1, \ldots, m_{h_k}$ of degree $k$ in the degree one variables $x_1, \ldots, x_{h_1}$, so that

$$h_l = \#\{m | m \text{ is a monomial of degree } l \text{ in variables } x_1, \ldots, x_{h_1},$$

such that $m | m_i$, for some $0 < i \leq h_k$.}

Now we can state a long standing conjecture of Stanley [16]:

**Conjecture 1 (Stanley)** The $h$-vector $(h_1(M), \ldots, h_k(M))$ of a rank $k$ matroid $M$ is a pure $O$-sequence.

This conjecture is still open for general matroids, though recently it has been deduced for cographic matroids using [11], i.e. for the Betti numbers of toric quiver varieties [6, Section 8]. Another attack on Stanley’s conjecture has been to deduce numerical inequalities between the numbers in a pure $O$-sequence and then prove these inequalities for the $h$-vector of a matroid complex. As an example Hibi [8] proved that for a pure $O$-sequence one has

$$h_i \leq h_j,$$  (11)

where $i \leq j \leq k - i$ and in particular that

$$h_1 \leq h_2 \leq \cdots \leq h_{\lfloor \frac{k}{2} \rfloor};$$

this was in turn proven for $h$-vectors of matroid complexes by Chari [2].

Here we strengthen this result by proving the following

**Theorem 6.2** A pure $O$-sequence $(h_1, h_2, \ldots, h_k)$ satisfies (11) and the $g$-inequalities .

**Corollary 6.3** Theorem 5.1 is a consequence of Stanley’s Conjecture 6.
Proof of Theorem 6.2. We are going to follow the structure of Proof 2 of Theorem 4.1. Namely take a pure $O$-sequence $(h_1, h_2, \ldots, h_k)$ with generating monomials $m_1, \ldots, m_{h_k}$ in variables $x_1, \ldots, x_{h_1}$. First we construct a graded ring

$$R = \frac{\mathbb{C}[\partial_{h_1}, \ldots, \partial_{h_k}]}{I}$$

$$I = \text{ann}(m_1) \cap \cdots \cap \text{ann}(m_{h_k})$$

which will be the analogue of the cohomology ring $H^*(Y, \mathbb{C})$ of a toric hyperkähler manifold. Here $\partial_i$ is a variable of degree one, which we think of as a differential operator, satisfying $\partial_i(x_j) = \delta_{ij}$. The ideal in the denominator is the ideal $I$ of polynomials in the $\partial_i$ which annihilate all the monomials $m_j$. Clearly $\dim R_j = h_j$. Then we construct graded rings

$$R^i_j = \frac{\mathbb{C}[\partial_{h_1}, \ldots, \partial_{h_k}]}{I_j}$$

$$I_j = \text{ann}(m_j)$$

for each monomial $m_j$, which will be the analogue of $H^*(X_j, \mathbb{C})$ (in fact it is useful to think about $R^i_j$ as the cohomology ring of the product of projective spaces of dimension given by the exponents in the monomial $m_j$). Because $I \subset I_j$, we have a natural map $p_j : R \to R^i_j$. The equation $I = \cap_j I_j$ now implies the analogue of (4), i.e. that the map

$$p = p_1 \times \cdots \times p_{h_k} : R \to R^1 \times \cdots \times R^{h_k}$$

is injective. Now take the degree 1 class $\omega = \sum_j \partial_j$. It is clear that the map $L^{k-2i}_j : R^i_j \to R^{k-i}_j$ given by $L^{k-2i}_j(\alpha) = \alpha p_j(\omega^{k-2i})$ is injective for $2i < k$. It follows e.g. if we think of $R^i_j$ as the cohomology ring of the product of projective spaces. Then $p_j(\omega)$ corresponds to the natural ample class, so the hard Lefschetz theorem implies injectivity of $L^{k-2i}_j$. Of course in this case one can check this result by hand for the explicitly defined rings $R^i_j$. The injectivity of $p$ and of $L^{k-2i}_j$ implies the injectivity of $L^{k-2i}_i : R_i \to R_{k-i}$, $L^{k-2i}_i(\alpha) = \alpha \omega^{k-2i}$ for $2i < k$. The result follows. $\square$
