Summary

Deep learning has significantly revolutionized the design of numerical algorithms for solving high-dimensional partial differential equations (PDEs). Yet the empirical successes of such approaches remains mysterious in theory. In deep learning-based PDE solvers, solving the original PDE is formulated into an expectation minimization problem with a PDE solution space discretized via deep neural networks. A global minimizer corresponds to a deep neural network that solves the given PDE. Typically, gradient descent-based methods are applied to minimize the expectation. This paper shows that gradient descent can identify a global minimizer of the optimization problem with a well-controlled generalization error in the case of two-layer neural networks in the over-parameterization regime (i.e., the network width is sufficiently large). The generalization error of the gradient descent solution does not suffer from the curse of dimensionality if the solution is in a Barron-type space. The theories developed here could form a theoretical foundation of deep learning-based PDE solvers.

Keywords. Deep learning, over-parametrization, partial differential equations, optimization convergence, generalization error.

AMS subject classifications: 68U99, 65N30 and 65N25.

1 Introduction

Deep learning, originated in computer science, has revolutionized many fields of science and engineering recently. This revolution also includes broad applications of deep learning in computational and applied mathematics, e.g., many breakthroughs in solving high-dimensional partial differential equations (PDEs) [7, 24, 2, 17, 22, 36, 41, 35, 20, 15]. The key idea of these approaches is to reformulate the PDE solution into a global minimizer of an expectation minimization problem, where deep neural networks (DNNs) are applied for discretization and the stochastic gradient descent (SGD) is adopted to solve the minimization problem. These methods probably date back to 1990’s (e.g., see [7, 24]) and were revisited recently [2, 22, 36, 41, 35] due to the significant development of GPU computing that accelerates DNN computation. Though these approaches have remarkable empirical successes, their theoretical justification remains vastly open.

For simplicity, let us use a PDE defined on a domain Ω in a compact form with equality constrains to illustrate the main idea, e.g.,

\[
\begin{align*}
L u &= f \quad \text{in } \Omega, \\
B u &= g \quad \text{on } \partial\Omega,
\end{align*}
\]  

(1.1)
where $\mathcal{L}$ is a differential operator and $\mathcal{B}$ is the operator for specifying an appropriate boundary condition. In the least squares-type methods, DNNs, denoted as $\phi(x; \theta)$ with a parameter set $\theta$, are applied to parametrize the solution space of the PDE and a best parameter set $\theta_D$ is identified via minimizing an expectation called the population risk (also known as the population loss):

$$
\theta_D = \arg\min_{\theta} R_D(\theta) := \mathbb{E}_{x \sim U(\Omega)} [\ell(\mathcal{L}\phi(x; \theta), f(x))] + \gamma\mathbb{E}_{x \sim U(\partial\Omega)} [\ell(\mathcal{B}\phi(x; \theta), g(x))],
$$

(1.2)

with a positive parameter $\gamma$ and a loss function typically taken as $\ell(y, y') = \frac{1}{2}|y - y'|^2$, where the expectation are taken with uniform distributions $U(\Omega)$ and $U(\partial\Omega)$ over $\Omega$ and $\partial\Omega$, respectively. To implement the expectation minimization above using the gradient descent method (GD), a discrete set of samples are randomly drawn to obtain an empirical risk (or empirical loss) function

$$
R_S(\theta) := \frac{1}{n} \sum_{i=1}^{n} \ell(\mathcal{L}\phi(x_i; \theta), f(x_i)) + \gamma\frac{1}{n} \sum_{i=1}^{n} \ell(\mathcal{B}\phi(x_i; \theta), g(x_i)),
$$

(1.3)

used in each GD iteration to update $\theta$. The set of random samples is usually renewed per iteration resulting in the SGD algorithm for minimizing (1.2). The theoretical foundation of the above deep learning-based PDE solver consists of mainly three questions:

1. **Approximation theory:** given a budget of the size of DNNs, e.g. width $N$ and depth $L$, or a budget of the total number of parameters $N_{\text{para}}$, what is the accuracy of $\phi(x; \theta_D)$ approximating the solution of the PDE?

2. **Optimization convergence:** under what condition can SGD converge to a global minimizer of (1.2) and (1.3)?

3. **Generalization analysis:** if only finitely many samples are available, how good is the global minimizer of (1.3) compared to the global minimizer of (1.2)?

Deep network approximation theory as the first foundation of deep learning-based PDE solvers has been developed to answer the first question above. It has been proved that DNNs admit powerful approximation capacity making them very attractive for high-dimensional problems. First, DNNs can lessen the curse of dimensionality for several function spaces, e.g., Barron spaces [1], Korobov spaces [30], band-limited functions [5, 32], compositional functions [34], smooth functions [44, 27, 31], and even general continuous functions [40]. Second, DNNs can achieve exponential approximation rates when target functions are sufficiently smooth, i.e., the approximation error exponentially decays when the number of parameters increases, for target functions in the polynomial spaces [43, 32, 27], the smooth function spaces [32, 25], the analytic function space [12], the function space admitting a holomorphic extension to a Bernstein polyellipse [33], and even general continuous functions [40]. Theories in deep network approximation have provided attractive upper bounds of the accuracy of $\phi(x; \theta_D)$ approximating the solution of the PDE in various function spaces. Characterizing deep network approximation in terms of $N$ and $L$ simultaneously might be more fundamental and indispensable in realistic applications than the characterization in terms of $N_{\text{para}}$. We refer reader to [39, 38, 27, 40, 42] for a series of works in terms of $N$ and $L$.

Though DNNs are powerful in terms of approximation theory, obtaining the best DNN $\phi(x; \theta_D)$ in (1.2) approximating the high-dimensional solution of a PDE is still challenging. It is conjectured that, under certain conditions, SGD is able to identify an approximate global minimizer of (1.2) with an accuracy depending on $N_{\text{para}}$ and the sample size $n$ for a wide class of PDEs. Though deep learning-based PDE solvers have been proposed since 1990s, there is no complete answer to this
conjecture. In this paper, assuming that the same set of random samples are used in minimizing (1.3), it is shown that GD can converge to a global minimizer of (1.3), denoted as $\theta_S$, as long as $N_{\text{para}}$ is sufficiently large depending on $n$, i.e., in the over-parametrization regime of deep learning. Furthermore, we will quantify how good the global minimizer $\theta_S$ of the empirical loss in (1.3) is compared to the global minimizer $\theta_D$ of the population loss in (1.2), when the empirical loss is regularized with a penalty term using the path norm of $\theta$ and the PDE solution is in a Barron-type space $\mathbb{B}$. Our analysis is based on two-layer neural networks and valid for a wide class of PDEs. The theory developed in this paper will serve as a milestone towards a complete answer of the conjecture mentioned above.

Though the convergence of deep learning-based regression under the over-parametrization assumption has been proposed recently [21, 8, 29, 9, 3, 6, 28], we would like to emphasize that the minimization of solving a PDE via (1.2) is much more difficult. In the case of solving PDEs, differential operators have significantly changed the optimization objective function and balancing between the differential operator and the boundary operator makes it more challenging to solve the optimization problem. For example, we consider a second order elliptic equation with variable coefficients, i.e., $L u = f$ where $L u = \sum_{\alpha, \beta=1}^d A_{\alpha \beta}(x) u x_{\alpha} x_{\beta}$. Given a two-layer neural network $\phi(x; \theta) = \sum_{k=1}^N a_k \sigma(w_k^T x)$ with an activation function $\sigma(z) = \max\{0, \frac{1}{2} z^3\}$ to parametrize the PDE solution, solving the original PDE via deep learning is equivalent to solving a regression problem with another type of neural network $f(x; \theta) := L \phi(x; \theta) = \sum_{k=1}^N a_k w_k^T A(x) w_k \sigma''(w_k^T x)$ to fit $f(x)$. Note that $\sigma''(z) = \text{ReLU}(z) = \max\{0, z\}$. Thus, the dependence of $f(x; \theta)$ on $w_k$ is essentially cubic rather than linear (more precisely, positive homogeneous). Moreover, the variable coefficients $A_{\alpha \beta}(x)$ lead to highly nonlinearity in the network $f(x; \theta)$ depending on $x$, since we do not make any assumption on the smoothness of $A(x)$. We develop very delicate analysis of the Rademacher complexity to overcome these difficulties. In contrast to many previous works such as [11], our a priori estimates do not require any truncation on $f(x; \theta)$ (or $\phi(x; \theta)$). This is important because a common truncation trick does not lead to the boundedness of $f(x; \theta)$ in our PDE solver. In fact, if one considers the standard truncation on $\phi(x; \theta)$, e.g., $T_{[0,1]} \phi(x; \theta) := \min\{\max\{\phi(x; \theta), 0\}, 1\}$, then $\mathcal{L}[T_{[0,1]} \phi(x; \theta)]$ might still be unbounded because $\mathcal{L}$ is a second order differential operator. Another naive trick is to truncate $f(x; \theta)$, i.e., $T_{[0,1]} f(x; \theta) := \min\{\max\{f(x; \theta), 0\}, 1\}$. But this does not make sense since we want to find a solution satisfying $\mathcal{L} \phi(x; \theta) \approx f(x)$ instead of $T_{[0,1]} \mathcal{L} \phi(x; \theta) \approx f(x)$.

This paper will be organized as follows. In Section 2 deep learning-based PDE solvers will be introduced in detail. In Section 3 our main theorems for the convergence and generalization analysis of GD for minimizing (1.3) will be presented. In Section 4 the proof of the GD convergence theorems will be shown. In Section 5 the proof of the generalization bound will be given. Finally, we conclude our paper in Section 6.

## 2 Deep Learning-based PDE Solvers

We will introduce deep learning-based PDE solvers with necessary notations in this paper in preparation for our main theorems in Section 3.

### 2.1 Notations and Basic Definitions

The main notations of this paper are listed as follows.

- Vectors and matrices are denoted in bold font. All vectors are column vectors.
For a parameter set \( \Theta \), \( \text{vec}\{\Theta\} \) denotes the vector consists of all the elements of \( \Theta \).

\([n]\) denotes \{1, 2, \ldots , n\}.

\( \| \cdot \|_1 \) and \( \| \cdot \|_\infty \) represent the \( \ell_1 \) and \( \ell_\infty \) norms of a vector, respectively.

Big “O” notation: for any functions \( g_1, g_2 : \mathbb{R} \to \mathbb{R}^+ \), \( g_1(z) = O(g_2(z)) \) as \( z \to +\infty \) means that \( g_1(z) \leq C g_2(z) \) for some constants \( C, z_0 \) and any \( z \geq z_0 \).

Small “o” notation: for any functions \( g_1, g_2 : \mathbb{R} \to \mathbb{R}^+ \), \( g_1(z) = o(g_2(z)) \) as \( z \to +\infty \) means that \( \lim_{z \to +\infty} \frac{g_1(z)}{g_2(z)} = 0 \).

Let \( \sigma : \mathbb{R} \to \mathbb{R} \) denote the activation function, e.g., \( \sigma(x) = \max\{0, \frac{1}{2}x^3\} \) is the activation function used in this paper. With the abuse of notations, we define \( \sigma : \mathbb{R}^d \to \mathbb{R}^d \) as \( \sigma(x) = (\max\{0, x_1\}, \ldots , \max\{0, x_d\})^T \) for any \( x = (x_1, \ldots , x_d)^T \in \mathbb{R}^d \), where \( \top \) denotes the transpose of a matrix. Similarly, for any function \( f \) defined on \( \mathbb{R} \) and vector \( x \in \mathbb{R}^d \), \( f(x) = [f(x_1), \ldots , f(x_d)]^T \).

Mathematically, DNNs are a form of function parametrization via the compositions of simple non-linear functions \(^{13}\). Let us focus on the so-called fully connected feed-forward neural network (FNN) defined below. The FNN is a general DNN structure that includes other advanced structures as its special cases, e.g., convolutional neural network \(^{13}\), ResNet \(^{18}\), and DenseNet \(^{19}\).

**Definition 2.1** (Fully connected feed-forward neural network (FNN)). An FNN of depth \( L \) defined on \( \mathbb{R}^d \) is the composition of \( L \) simple nonlinear functions as follows:

\[
\phi(x; \theta) := a^T h^{[L]} \circ h^{[L-1]} \circ \cdots \circ h^{[1]}(x),
\]

where \( h^{[l]}(x) = \sigma(W^{[l]} x + b^{[l]}) \) with \( W^{[l]} \in \mathbb{R}^{N_l \times N_{l-1}} \), \( b^{[l]} \in \mathbb{R}^{N_l} \) for \( l = 1, \ldots , L \), \( a \in \mathbb{R}^{N_0} \), \( N_0 = d \), and \( \sigma \) is a non-linear activation function. Each \( h^{[l]} \) is referred as a hidden layer, \( N_l \) is the width of the \( l \)-th layer, and \( L \) is called the depth of the FNN. \( \theta := \text{vec}\{a, \{W^{[l]}, b^{[l]}\}_{l=1}^L\} \) denotes the set of all parameters in \( \phi \).

Without loss of generality, we consider FNNs omitting \( b^{[l]} \)'s. In fact, for a network with \( b^{[l]} \)'s, one can simply set \( \tilde{x} = (x^T, 1)^T \) and \( \tilde{W}^{[l]} = (W^{[l]}, b^{[l]}) \) for each \( l \in [L] \), and work on \( \theta = \text{vec}\{a, \{W^{[l]}\}_{l=1}^L\} \) by noting that \( \tilde{W}^{[l]} \tilde{x} = W^{[l]} x + b^{[l]} \).

In deep learning-based PDE solvers, deep network approximation can be applied to quantify the approximation error of \( \phi(x; \theta_D) \) approximating the PDE solution \( u(x) \) given the depth and width of the DNN, where \( \theta_D \) is a global minimizer of the population loss \( R_D(\theta) \) in \(^{[1,2]}\). For example, for the smooth function space \( C^s([0, 1]^d) \), the following theorem from \(^{[27]}\) quantifies a nearly optimal approximation error of DNNs.

**Theorem 2.1** (Smooth function approximation \(^{[27]}\)). Give a function \( f \in C^s([0, 1]^d) \) with \( s \in \mathbb{N}^+ \), for any \( N, L \in \mathbb{N}^+ \), there exists a ReLU FNN \( \phi \) with width \( C_1 d (N + 2) \log_2(4N) \) and depth \( C_2 (L + 2) \log_2(2L) + 2d \) such that

\[
\|f - \phi\|_{L^\infty([0,1]^d)} \leq C_3 \|f\|_{C^s([0,1]^d)} N^{-2s/d} L^{-2s/d},
\]

where \( C_1 = 22s^{d+1}3^d \), \( C_2 = 18s^2 \), and \( C_3 = 85(s+1)^d 8^s \).
Theorem 2.1 indicates that the smoothness of target functions plays an important role in the approximation rate. The smoother $f$ is, the better the approximation rate is. For highly smooth functions, e.g., $s \gtrsim d$, deep network approximation can conquer the curse of dimensionality when either $N$ and/or $L$ increase. Actually, as long as target functions are sufficiently smooth, e.g., in the Barron space $[1, 23, 11]$, two-layer neural networks have already been able to avoid the curse of dimensionality with a prefactor bounded by a path norm.

To analyze PDE solvers, we introduce a new kind of Barron functions with their associated Barron norm, and a path norm defined below.

**Definition 2.2 (Path norm).** The path norm of a two-layer neural network

$$\phi(x; \theta) = \sum_{k=1}^{N} a_k \sigma(w_k^\top x),$$

with an activation function $\sigma$ and a parameter set $\theta$ is defined as

$$\|\theta\|_P := \sum_{i=1}^{N} |a_i| \|w_j\|_1^3.$$  

**Definition 2.1.** A function $f : \Omega \to \mathbb{R}$ is called a Barron-type function if $f$ has an integral representation

$$f(x) = E_{(u,w) \sim \rho}[w^\top A(x)w\sigma''(w^\top x) + b^\top(x)w\sigma'(w^\top x) + c(x)\sigma(w^\top x)] \quad \text{for all } x \in \Omega,$$

where $\rho$ is a probability distribution over $\mathbb{R}^{d+1}$. The associated Barron norm of a Barron-type function is defined as

$$\|f\|_B := \inf_{\rho \in \mathcal{P}_f} (E_{(u,w) \sim \rho}[a^2 \|w\|_1^6])^{1/2},$$

where $\mathcal{P}_f = \{\rho | f(x) = E_{(u,w) \sim \rho}[w^\top A(x)w\sigma''(w^\top x) + b^\top(x)w\sigma'(w^\top x) + c(x)\sigma(w^\top x)], x \in \Omega\}$. The Barron-type space is defined as $\mathcal{B}(\Omega) = \{f : \Omega \to \mathbb{R} | \|f\|_B < \infty\}$.

Since $R_D(\theta)$ cannot be realized in realistic applications due to the fact that the empirical loss $R_S(\theta)$ of finitely many samples is actually used in the computation, an immediate question is: how well $\phi(x; \theta_S) \approx \phi(x; \theta_D)$? Here $\theta_S$ is a global minimizer when we minimize the empirical loss $R_S(\theta)$. This is the generalization error analysis of deep learning-based PDE solvers and we will use the Rademacher complexity below to estimate the generalization error in terms of $|R_D(\theta_S) - R_S(\theta_S)|$.

**Definition 2.3 (The Rademacher complexity of a function class $\mathcal{F}$).** Given a sample set $S = \{z_1, \ldots, z_n\}$ on a domain $\mathcal{Z}$, and a class $\mathcal{F}$ of real-valued functions defined on $\mathcal{Z}$, the empirical Rademacher complexity of $\mathcal{F}$ on $S$ is defined as

$$\text{Rad}_S(\mathcal{F}) = \frac{1}{n} \mathbb{E}_\tau \left[ \sup_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^{n} \tau_i f(z_i) \right],$$

where $\tau_1, \ldots, \tau_n$ are independent random variables drawn from the Rademacher distribution, i.e., $\mathbb{P}(\tau_i = +1) = \mathbb{P}(\tau_i = -1) = \frac{1}{2}$ for $i = 1, \ldots, n$.  

5
2.2 Expectation minimization

We will focus on the least squares method in (1.2) for the boundary value problem (BVP) in (1.1) to discuss the expectation minimization, though the expectation minimization can either be formulated from the least squares method [2, 41, 35] or the variational formulation [10, 26]. As we shall see in the next subsection, an initial value problem (IVP) can also be formulated into a BVP and solved by the expectation minimization in this subsection.

The objective function in (1.2) consists of two parts: one part for the PDE operator in the domain interior and another part for the boundary condition at the boundary. Therefore, GD has to balance between these two parts and its performance heavily relies on the choice of the parameter $\gamma$ in (1.2). To remove the hyper-parameter $\gamma$ and solve the balancing issue, we will introduce special DNNs in [16, 14] satisfying various boundary conditions by design, i.e., $B\phi(x; \theta) = g(x)$ is always fulfilled on $\partial \Omega$. Then the expectation minimization in (1.2) is reduced to

$$\theta_D = \arg \min_{\theta} R_D(\theta) := \mathbb{E}_{x \in \Omega} [\ell(\mathcal{L}\phi(x; \theta), f(x))].$$

(2.1)

Special neural networks for three types of boundary conditions will be introduced. Without loss of generality, we will take the example of one-dimensional problems on the domain $\Omega = [a, b]$. Networks for more complicated boundary conditions in high-dimensional domains can be constructed similarly.

Case 1. Dirichlet Boundary Conditions: $u(a) = a_0, \ u(b) = b_0$.

In this case, two special functions $h_1(x)$ and $h_2(x)$ are used to augment a neural network $\tilde{\phi}(x; \theta)$ to construct the final neural network $\phi(x; \theta)$ as the solution network:

$$\phi(x; \theta) = h_1(x)\tilde{\phi}(x; \theta) + h_2(x).$$

$h_1(x)$ and $h_2(x)$ are chosen such that $\phi(x; \theta)$ automatically satisfies the Dirichlet boundary conditions no matter what $\theta$ is. Then $\phi(x; \theta)$ is trained to satisfy the differential operator in the interior of the domain $\Omega$ by solving (2.1).

To achieve this goal, $h_1(x)$ and $h_2(x)$ are constructed for two purposes: 1) construct $h_1(x)$ such that $h_1(x)\tilde{\phi}(x; \theta)$ satisfies the homogeneous Dirichlet boundary condition; 2) construct $h_2(x)$ such that $h_2(x)$ satisfies the given inhomogeneous Dirichlet boundary conditions. Therefore, $h_1(x)$ can be set as

$$h_1(x) = (x - a)^{p_a}(x - b)^{p_b},$$

where $0 < p_a, p_b \leq 1$, and $h_2(x)$ can be chosen as

$$h_2(x) = (b_0 - a_0)(x - a)/(b - a) + a_0.$$

Note that $p_a$ and $p_b$ should be chosen appropriately to avoid introducing a singular function that $\tilde{\phi}(x; \theta)$ needs to approximate. For instance, if the exact PDE solution is $u(x) = (x - a)^s(x - b)^s v(x) + h_1(x)$ with $v(x)$ as a smooth function and $s > 0$, $p_a = p_b > s$ results in $\tilde{\phi}(x; \theta) \approx (x - a)^{s-p_a}(x - b)^{s-p_b} v(x)$, which makes the approximation very challenging.

Case 2. Mixed Boundary Conditions: $u'(a) = a_0, \ u(b) = b_0$.

Similar to Case 1, two special functions $h_1(x)$ and $h_2(x)$ are used to augment a neural network $\tilde{\phi}(x; \theta)$ to construct the final neural network $\phi(x; \theta)$ as the solution network:

$$\phi(x; \theta) = h_1(x)\tilde{\phi}(x; \theta) + h_2(x).$$
\( h_1(x) \) and \( h_2(x) \) are chosen such that \( \phi(x; \theta) \) automatically satisfies the mixed boundary conditions no matter what \( \theta \) is. Then \( \phi(x; \theta) \) is trained to satisfy the differential operator in the interior of the domain \( \Omega \) by solving (2.1).

To achieve this goal, \( h_1(x) \) and \( h_2(x) \) are constructed as

\[
h_1(x) = (x - a)^{p_a}
\]

with \( 1 < p_a \leq 2 \) and \( h_2(x) \) can be chosen as

\[
h_2(x) = -(b - a)^{p_a} \phi(b; \theta) + a_0 x + b_0 - a_0 b.
\]

**Case 3. Neumann Boundary Conditions:** \( u'(a) = a_0, \ u'(b) = b_0 \).

Similar to Case 1 and 2, we augment a neural network \( \hat{\phi}(x; \theta) \) to construct the final neural network \( \phi(x; \theta, c_1, c_2) \) as the solution network:

\[
\phi(x; \theta, c_1, c_2) = \exp \left( \frac{p_a x}{a - b} \right) (x - a)^{p_a} \left( (x - b)^{p_b} \hat{\phi}(x; \theta) + c_2 \right) + c_1 + \frac{(b_0 - a_0)}{2(b - a)} (x - a)^2 + a_0 x.
\]

where \( 1 < p_a, p_b \leq 2 \), \( c_1 \) and \( c_2 \) are two parameters to be trained together with \( \theta \). Then \( \phi(x; \theta, c_1, c_2) \) automatically satisfies the Neumann boundary conditions no matter what parameters are and \( \phi(x; \theta, c_1, c_2) \) is trained to satisfy the differential operator in the interior of the domain \( \Omega \) by solving (2.1).

### 2.3 Scope of analysis and applications

In Section 2.2, we have simplified the optimization problem from (1.2) to (2.1) for BVP in (1.1). Now we will show that various initial/boundary value problems can be formulated as a BVP in the form of (1.1). This helps us to simplify the optimization convergence and generalization analysis of deep learning-based PDE solvers to the case of BVP in (1.1) solved by (2.1). The analysis of a larger scope of applications has been naturally included in the analysis for BVPs.

Let us assume that the domain \( \Omega \subset \mathbb{R}^d \) is bounded. Typical PDE problems of interest can be summarized as:

- **Elliptic equation:**
  \[
  \mathcal{L}u(x) = f(x) \quad \text{in } \Omega, \\
  \mathcal{B}u(x) = g_0(x) \quad \text{on } \partial \Omega.
  \]  
  \[(2.2)\]

- **Parabolic equation:**
  \[
  \frac{\partial u(x, t)}{\partial t} - \mathcal{L}u(x, t) = f(x, t) \quad \text{in } \Omega \times (0, T), \\
  \mathcal{B}u(x, t) = g_0(x, t) \quad \text{on } \partial \Omega \times (0, T), \\
  u(x, 0) = h_0(x) \quad \text{in } \Omega.
  \]  
  \[(2.3)\]

- **Hyperbolic equation:**
  \[
  \frac{\partial^2 u(x, t)}{\partial t^2} - \mathcal{L}u(x, t) = f(x, t) \quad \text{in } \Omega \times (0, T), \\
  \mathcal{B}u(x, t) = g_0(x, t) \quad \text{on } \partial \Omega \times (0, T), \\
  u(x, 0) = h_0(x), \quad \frac{\partial u(x, 0)}{\partial t} = h_1(x) \quad \text{in } \Omega.
  \]  
  \[(2.4)\]
In the above equations, \( u \) is the unknown solution function; \( f, g_0, h_0, h_1 \) are given data functions; \( \mathcal{L} \) is a spatial differential operator with respect to \( x \); \( \mathcal{B} \) is a boundary operator specifying a certain type of boundary conditions.

As discussed in [16], when the temporal variable \( t \) is treated as an extra spatial coordinate, we can unify the above initial/boundary value problems in (2.2)-(2.4) in the following form

\[
\mathcal{L}u(y) = f(y) \text{ in } Q,
\]
\[
\mathcal{B}u(y) = g(y) \text{ in } \Gamma,
\]

where \( y \) includes the spatial variable \( x \) and possibly the temporal variable \( t \); \( \mathcal{L}u = f \) represents a generic time-independent PDE; \( \mathcal{B}u = g \) specifies the original boundary condition on \( x \) and possibly the initial condition of \( t \); \( Q \) and \( \Gamma \) are the corresponding new domains of the equations. For the purpose of convenience, we will still use the BVP in (1.1) instead of (2.5) afterwards.

Though deep learning-based PDE solvers work for high-order differential equations in general domains, we consider second order differential equations with variable coefficients in \( \Omega = [0, 1] \) in our analysis. The generalization to high-order differential equations and other domains follows straightforwardly and we leave it as future work. We will use the second order differential operator \( \mathcal{L} \) in a non-divergence form

\[
\mathcal{L}u = \sum_{\alpha,\beta=1}^{d} A_{\alpha\beta}(x)u_{x_{\alpha}x_{\beta}} + \sum_{\alpha=1}^{d} b_{\alpha}(x)u_{x_{\alpha}} + c(x)u.
\]

(2.6)

If \( \mathcal{L} \) is in a divergence form, e.g.,

\[
\mathcal{L}u = \sum_{\alpha,\beta=1}^{d} (A_{\alpha\beta}(x)u_{x_{\alpha}})_{x_{\beta}} + \sum_{\alpha=1}^{d} b_{\alpha}(x)u_{x_{\alpha}} + c(x)u,
\]

then we can represent it in a non-divergence form as

\[
\mathcal{L}u = \sum_{\alpha,\beta=1}^{d} A_{\alpha\beta}(x)u_{x_{\alpha}x_{\beta}} + \sum_{\alpha=1}^{d} \hat{b}_{\alpha}(x)u_{x_{\alpha}} + c(x)u
\]

with

\[
\hat{b}_{\alpha} = b_{\alpha} + \sum_{\beta=1}^{d} \frac{\partial A_{\alpha\beta}}{\partial x_{\beta}}.
\]

Recall that we introduce two functions \( h_1(x) \) and \( h_2(x) \) to augment a neural network \( \tilde{\phi}(x; \theta) \) to construct the final neural network

\[
\phi(x; \theta) = h_1(x)\tilde{\phi}(x; \theta) + h_2(x)
\]

as the solution network that automatically satisfies given Dirichlet boundary conditions, which makes it sufficient to solve the optimization problem in (2.3) to get the desired neural network. In this case, \( \mathcal{L}\phi(x; \theta) = f(x) \) is equivalent to \( \tilde{\mathcal{L}}\tilde{\phi}(x; \theta) = \tilde{f}(x) \), where

\[
\tilde{\mathcal{L}} = \sum_{\alpha,\beta=1}^{d} \tilde{A}_{\alpha\beta}(x)u_{x_{\alpha}x_{\beta}} + \sum_{\alpha=1}^{d} \tilde{b}_{\alpha}(x)u_{x_{\alpha}} + \tilde{c}(x),
\]

\[
\tilde{A}_{\alpha\beta}(x) = A_{\alpha\beta}(x)h_1(x),
\]

8
\[\tilde{b}_\alpha(x) = b_\alpha(x) h_1(x) + \sum_{\beta=1}^{d} (A_{\alpha\beta}(x) + A_{\beta\alpha}(x)) \partial_{x\beta} h_1(x),\]

\[\tilde{c}(x) = \sum_{\alpha,\beta=1}^{d} A_{\alpha\beta}(x) \partial_{x\alpha} \partial_{x\beta} h_1(x) + \sum_{\alpha=1}^{d} b_\alpha(x) \partial_{x\alpha} h_1(x) + c(x) h_1(x),\]

and

\[\tilde{f}(x) = f(x) - \mathcal{L}(h_2(x)).\]

Therefore, the optimization convergence and generalization analysis of (2.1) is equivalent to

\[\theta_D = \arg \min_{\theta} R_D(\theta) := \mathbb{E}_{x \in \Omega} \left[ \ell(\tilde{\mathcal{L}} \tilde{\phi}(x; \theta), \tilde{f}(x)) \right],\quad (2.7)\]

which gives

\[\phi(x; \theta_D) = h_1(x) \tilde{\phi}(x; \theta_D) + h_2(x)\]

as a best solution to the PDE in (1.1) parametrized by DNNs. The corresponding empirical risk is

\[R_S(\theta) := \frac{1}{n} \sum_{\{x_i\}_{i=1}^{n} \subset \Omega} \ell(\tilde{\mathcal{L}} \tilde{\phi}(x_i; \theta), \tilde{f}(x_i)),\quad (2.8)\]

which gives \(\theta_S = \arg \min_{\theta} R_S(\theta)\) and

\[\phi(x; \theta_S) = h_1(x) \tilde{\phi}(x; \theta_S) + h_2(x).\]

Similarly, in the case of other two types of boundary conditions, the corresponding optimization problem in (1.2) can also be transformed to (2.7) and its discretization in (2.8) with an appropriate differential operator \(\tilde{\mathcal{L}}\) and a right-hand-side function \(\tilde{f}\).

In sum, the discussion in Section 2.2 and here indicates that, the optimization and generalization analysis of deep learning-based PDE solvers for various IVPs and BVPs with different boundary conditions can be reduced to the analysis of (2.7) and (2.8) with \(\tilde{\mathcal{L}}\) in a non-divergence form. In the next section, we will present our main theorems for this analysis. For simplicity, we will still use the notation of \(\mathcal{L}\) and \(f\) instead of \(\tilde{\mathcal{L}}\) and \(\tilde{f}\) in our analysis afterwards.

### 3 Main results

In this section, we introduce our main results on the convergence of GD and the generalization error of neural network-based least squares solvers for PDEs using two-layer neural networks on \(\Omega = [0,1]^d\). Throughout our analysis, we focus on second-order differential operators \(\mathcal{L}\) given in (2.6) satisfying the assumption below.

**Assumption 3.1 (Symmetry and boundedness of \(\mathcal{L}\)).** Throughout the analysis of this paper, we assume \(\mathcal{L}\) in (2.6) satisfies the condition: there exists \(M \geq 1\) such that for all \(x \in \Omega = [0,1]^d\), \(\alpha, \beta \in [d]\), we have

\[|A_{\alpha\beta}(x)| \leq M, \quad |b_\alpha(x)| \leq M, \quad \text{and} \quad |c(x)| \leq M.\]  

\(^1\)The upper bound \(M\) is not necessarily greater than 1. We set this for simplicity.
First, we show that, under suitable assumptions, the empirical risk $R_S(\theta)$ of the PDE solution represented by an over-parametrized two-layer neural networks converges to zero, i.e., achieving a global minimizer, with a linear convergence rate by GD. In particular, as discussed in Section 2, it is sufficient to prove the convergence for minimizing the empirical loss

$$\theta_S = \arg\min_\theta R_S(\theta) := \frac{1}{n} \sum_{S=\{x_i\}_{i=1}^n \subset \Omega} \ell(\mathcal{L}(x_i; \theta), f(x_i)), \quad (3.2)$$

where $S := \{x_i\}_{i=1}^n$ is a given set of i.i.d. samples with the uniform distribution $\mathcal{D}$ over $\Omega = [0, 1]^d$, and the two-layer neural network used here is constructed as

$$\phi(x; \theta) = \sum_{k=1}^N a_k \sigma(w_k^T x), \quad (3.3)$$

where for $k \in [N]$, $a_k \in \mathbb{R}$, $w_k \in \mathbb{R}^d$, $\theta = \text{vec}\{a_k, w_k\}_{k=1}^N$, and $\sigma(x) = \max\left\{\frac{1}{2}x^3, 0\right\}$. Our main result of the linear convergence rate is summarized in Theorem 3.1 below.

**Theorem 3.1 (Linear convergence rate).** Let $\theta^0 := \text{vec}\{a_k^0, w_k^0\}_{k=1}^N$ at the GD initialization for solving (3.2), where $a_k^0 \sim \mathcal{N}(0, \gamma^2)$ and $w_k^0 \sim \mathcal{N}(0, I_d)$ with any $\gamma \in (0, 1)$. Let $C_d := \mathbb{E}\|w\|^2 < +\infty$ with $w \sim \mathcal{N}(0, I_d)$ and $\lambda_S$ be a positive constant in Assumption 4.1. For any $\delta \in (0, 1)$, if

$$\begin{align*}
N &\geq \max \left\{ \frac{512n^4M^4C_d}{\lambda_S^2\delta^2}, \frac{200\sqrt{2Md^3n\log(4N(d+1)/\delta)}\sqrt{R_S(\theta^0)}}{\lambda_S}, \frac{2^{23}M^3d^3n^2(\log(4N(d+1)/\delta))^4\sqrt{R_S(\theta^0)}}{\lambda_S^2} \right\}, \quad (3.4)
\end{align*}$$

then with probability at least $1 - \delta$ over the random initialization $\theta^0$, we have, for all $t \geq 0$,

$$R_S(\theta(t)) \leq \exp\left(-\frac{N\lambda_S t}{n}\right) R_S(\theta^0).$$

**Remark 3.1.** For the estimate of $R_S(\theta^0)$, see Lemma 4.2. In particular, if $\gamma = O(\sqrt{1/\sqrt{N\log N}})$, then $R_S(\theta^0) = O(1)$. One may also use the Anti-Symmetrical Initialization (ASI) [45], a general but simple trick that ensures $R_S(\theta^0) \leq \frac{1}{2}$.

Second, we prove that the a posteriori generalization error $|R_D(\theta) - R_S(\theta)|$ is bounded by $O\left(\frac{\|\theta\|_p}{\sqrt{n}}\right)$, where $\|\theta\|_p$ is the path norm introduced in Definition 2.2 and the a priori generalization error $R_D(\theta_{S,\lambda})$ is bounded by $O\left(\frac{\|f\|_B}{N}\right) + O\left(\frac{\|f\|_B}{\sqrt{n}}\right)$, where $\|f\|_B$ is the Barron norm for Barron-type functions $f(x)$ introduced in Definition 2.1 and $\theta_{S,\lambda}$ is a global minimizer of a regularized empirical loss using the path norm. Our results of the generalization errors can be summarized in Theorems 3.2 and 3.3 below.

**Theorem 3.2 (A posteriori generalization bound).** For any $\delta \in (0, 1)$, with probability at least $1 - \delta$ over the choice of random samples $S := \{x_i\}_{i=1}^n$ in (3.2), for any two-layer neural network $\phi(x; \theta)$ in (3.3), we have

$$|R_D(\theta) - R_S(\theta)| \leq \frac{(\|\theta\|_p + 1)^3}{\sqrt{n}} 2\sqrt{2M^2(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(\pi^2/3\delta)})}.$$
Theorem 3.3 (A priori generalization bound). Suppose that $f(x)$ is in the Barron-type space $\mathcal{B}([0, 1]^d)$ and $\lambda \geq 8\sqrt{2}M^2(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)})$. Let

$$\theta_{S, \lambda} = \arg \min_{\theta} J_{S, \lambda}(\theta) := R_S(\theta) + \frac{\lambda}{\sqrt{n}} \|\theta\|_2^2.$$  

Then for any $\delta \in (0, 1)$, with probability at least $1 - \delta$ over the choice of random samples $S := \{x_i\}_{i=1}^n$ in (3.2), we have

$$R_D(\theta_{S, \lambda}) := \mathbb{E}_{x \sim D} \frac{1}{2}(\mathcal{L}\phi(x; \theta_{S, \lambda}) - f(x))^2 \leq \frac{6M^2\|f\|_B^2}{N} + \frac{8\|f\|_B^2 + 2}{\sqrt{n}}(\lambda + 8\sqrt{2}M^2)(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)}). \quad (3.6)$$

The proof of Theorem 3.1 will be given in Section 4 and the proofs of Theorems 3.2 and 3.3 will be presented in Section 5.

4 Global Convergence of Gradient Descent

In this section, we will prove the global convergence of GD with a linear convergence rate for deep learning-based PDE solvers as stated in Theorem 3.1. We will first summarize the notations and assumptions for the proof of Theorem 3.1 in Section 4.1. Several important lemmas will be proved in Section 4.2. Finally, Theorem 3.1 is proved in Section 4.3.

4.1 Notations and main ideas

Let us first summarize the notations and assumptions used in the proof of Theorem 3.1.

Recall that we use the two-layer neural network $\phi(x; \theta)$ in (3.3) with $\theta = \text{vec}\{a_k, w_k\}_{k=1}^N$. In the GD iteration, we use $t$ to denote the iteration or the artificial time variable in the gradient flow. Hence, we define the following notations for the evolution of parameters at time $t$:

$$a_k^t := a_k(t), \quad w_k^t := w_k(t), \quad \theta^t := \theta(t) := \text{vec}\{a_k^t, w_k^t\}_{k=1}^N.$$  

In the analysis, we also use $\bar{a}^t := \bar{a}(t) := \gamma^{-1}a_k(t) \sim \mathcal{N}(0, 1)$ with $0 < \gamma < 1$, e.g., $\gamma = \frac{1}{\sqrt{N}}$ or $\gamma = \frac{1}{\sqrt{N}}$. Similarly, we can introduce $t$ to other functions or variables depending on $\theta(t)$. When the dependency of $t$ is clear, we will drop the index $t$. In the initialization of GD, we set

$$a_0^0 := a_k(0) \sim \mathcal{N}(0, \gamma^2), \quad w_0^0 := w_k(0) \sim \mathcal{N}(0, I_d), \quad \theta^0 := \theta(0) := \text{vec}\{a_k^0, w_k^0\}_{k=1}^N. \quad (4.1)$$

Note that we use $\sigma(x) = \max\{\frac{1}{2}x^2, 0\}$ as the activation of our two-layer neural network. Therefore, $\sigma'(x) = \max\{x, 0\}$, and $\sigma''(x) = \text{ReLU}(x) = \max\{x, 0\}$. For simplicity, we define

$$f_{\theta}(x) := f(x; \theta) = \mathcal{L}\phi(x; \theta) = \sum_{k=1}^N a_k[w_k^T A(x)w_k\sigma''(w_k^T x) + b^T(x)w_k\sigma'(w_k^T x) + c(x)\sigma(w_k^T x)], \quad (4.2)$$

which can be treated as a special two-layer neural network for a regression problem $f_{\theta}(x) \approx f(x)$.
For simplicity, we denote $e_i = f_\theta(x_i) - f(x_i)$ for $i \in [n]$ and $e = (e_1, e_2, \ldots, e_n)$. Then the empirical risk can be written as

$$R_S(\theta) = \frac{1}{2n} \sum_{i=1}^{n} (f_\theta(x_i) - f(x_i))^2 = \frac{1}{2n} e^\top e.$$  

Hence, the GD dynamics is

$$\dot{\theta} = -\nabla_\theta R_S(\theta),$$  

or equivalently in terms of $a_k$ and $w_k$ as follows:

$$\dot{a}_k = -\nabla_{a_k} R_S(\theta) = -\frac{1}{n} \sum_{i=1}^{n} e_i \left[ w_k^\top A(x_i)w_k\sigma''(w_k^\top x_i) + b_k^\top(x_i)w_k\sigma'(w_k^\top x_i) + c(x_i)\sigma(w_k^\top x_i) \right],$$

$$\dot{w}_k = -\nabla_{w_k} R_S(\theta) = -\frac{1}{n} \sum_{i=1}^{n} e_i a_k \left[ 2A(x_i)w_k\sigma''(w_k^\top x_i) + w_k^\top A(x_i)w_k\sigma'(w_k^\top x_i) x_i 
+ \sigma'(w_k^\top x_i)b(x_i) + b_k^\top(x_i)w_k\sigma''(w_k^\top x_i) x_i + c(w_i)\sigma'(w_k^\top x_i) x_i \right].$$

Adopting the neuron tangent kernel point of view [21], in the case of a two-layer neural network with an infinite width, the corresponding kernels $k^{(a)}$ for parameters in the last linear transform and $k^{(w)}$ for parameters in the first layer are functions from $\Omega \times \Omega$ to $\mathbb{R}$ defined by

$$k^{(a)}(x, x') := \mathbb{E}_{w \sim N(0, I_d)} g^{(a)}(w; x, x'),$$

$$k^{(w)}(x, x') := \mathbb{E}_{(a, w) \sim N(0, I_{d+1}, I_{d+1})} g^{(w)}(a, w; x, x'),$$

where

$$g^{(a)}(w; x, x') := \left[ w^\top A(x)w\sigma''(w^\top x) + b^\top(x)w\sigma'(w^\top x) + c(x)\sigma(w^\top x) \right],$$

$$g^{(w)}(a, w; x, x') := a^2 \left[ 2A(x)w\sigma''(w^\top x) + w^\top A(x)w\sigma'(w^\top x) x + \sigma'(w^\top x)b(x) 
+ b^\top(x)w\sigma''(w^\top x) x + c(w)\sigma'(w^\top x) x \right].$$

These kernels evaluated at $n \times n$ pairs of samples lead to $n \times n$ Gram matrices $K^{(a)}$ and $K^{(w)}$ with $K^{(a)}_{ij} = k^{(a)}(x_i, x_j)$ and $K^{(w)}_{ij} = k^{(w)}(x_i, x_j)$, respectively. Our analysis requires the matrix $K^{(a)}$ to be positive definite, which has been verified for regression problems under mild conditions on random training data $S = \{x_i\}_{i=1}^n$ and can be generalized to our case. Hence, we assume this as follows for simplicity.

**Assumption 4.1.** We assume that

$$\lambda_S := \lambda_{\min}(K^{(a)}) > 0.$$  

For a two-layer neural network with $N$ neurons, the $n \times n$ Gram matrix $G(\theta) = G^{(a)}(\theta) + G^{(w)}(\theta)$ is given by the following expressions for the $(i, j)$-th entry

$$G^{(a)}_{ij}(\theta) := \frac{1}{N} \sum_{k=1}^{N} g^{(a)}(w_k; x_i, x_j),$$

$$G^{(w)}_{ij}(\theta) := \frac{1}{N} \sum_{k=1}^{N} g^{(w)}(a_k, w_k; x_i, x_j).$$
Clearly, $G^{(a)}(\theta)$ and $G^{(w)}(\theta)$ are both positive semi-definite for any $\theta$. By using the Gram matrix $G(\theta)$, we have the following evolution equations to understand the dynamics of GD:

$$\frac{df_{\theta}(x_i)}{dt} = -\frac{1}{n} \sum_{j=1}^{n} G_{ij}(\theta)(f_{\theta}(x_j) - f(x_j))$$

and

$$\frac{dR_{S}(\theta)}{dt} = -\|\nabla_{\theta} R_{S}(\theta)\|^2 = -\frac{N}{n^2} e^{\top} G(\theta) e \leq -\frac{N}{n^2} e^{\top} G^{(a)}(\theta) e. \tag{4.4}$$

Our goal is to show that the above evolution equation has a solution $f_{\theta}(x_i)$ converges to $f(x_i)$ for all training samples $x_i$, or equivalently, to show that $R_{S}(\theta)$ converges to zero. These goals are true if the smallest eigenvalue $\lambda_{\min}(G^{(a)}(\theta))$ of $G^{(a)}(\theta)$ has a positive lower bound uniformly in $t$, since in this case we can solve (4.4) and bound $R_{S}(\theta)$ with a function in $t$ converging to zero when $t \to \infty$ as shown in Lemma 4.3. In fact, a uniform lower bound of $\lambda_{\min}(G^{(a)}(\theta))$ can be $\frac{1}{2} \lambda_S$, which can be proved in the following three steps:

- **(Initial phase)** By Assumption 4.1 of $K^{(a)}$, we can show $\lambda_{\min}(G^{(a)}(\theta(0))) \approx \lambda_S$ in Lemma 4.3 using the observation that $K^{(a)}_{ij}$ is the mean of $g(w; x_i, x_j)$ over the normal random variable $w$, while $G^{(a)}_{ij}(\theta(0))$ is the mean of $g(w; x_i, x_j)$ with $N$ independent realizations.

- **(Evolution phase)** The GD dynamics results in $\theta(t) \approx \theta(0)$ under the assumption of over-parametrization as shown in Lemma 4.5 which indicates that

$$\lambda_{\min}(G^{(a)}(\theta(t))) \approx \lambda_{\min}(G^{(a)}(\theta(0))).$$

- **(Final phase)** To show the uniform bound $\lambda_{\min}(G^{(a)}(\theta(t))) \geq \frac{1}{2} \lambda_S$ for all $t \geq 0$, we introduce a stopping time $t^{*}$ via

$$t^{*} = \inf\{t \mid \theta(t) \notin M(\theta^0)\}, \tag{4.5}$$

where

$$M(\theta^0) := \left\{ \theta \mid \|G^{(a)}(\theta) - G^{(a)}(\theta^0)\|_{F} \leq \frac{1}{4} \lambda_S \right\},$$

and show that $t^{*}$ is in fact equal to infinity in the final proof of Theorem 3.1 in Section 4.3.

### 4.2 Proofs of lemmas for Theorem 3.1

In this subsection, we will prove several lemmas in preparation for the proof of Theorem 3.1.

**Lemma 4.1.** For any $\delta \in (0, 1)$ with probability at least $1 - \delta$ over the random initialization in (4.1), we have

$$\max_{k \in [N]} \{\|a_k^0\|, \|w_k^0\|_{\infty}\} \leq \sqrt{\frac{2 \log \left(\frac{2N(d+1)}{\delta}\right)}{\delta}}, \tag{4.6}$$

$$\max_{k \in [N]} \{\|a_k^0\|\} \leq \sqrt{\frac{2 \log \left(\frac{2N(d+1)}{\delta}\right)}{\delta}}.$$  

**Proof.** If $X \sim \mathcal{N}(0, 1)$, then $\mathbb{P}(|X| > \varepsilon) \leq 2e^{-\frac{\varepsilon^2}{2}}$ for all $\varepsilon > 0$. Since $a_k^0 \sim \mathcal{N}(0, 1)$, $(w_k^0)^{\alpha} \sim \mathcal{N}(0, 1)$ for $k \in [N], \alpha \in [d]$ and they are all independent, by setting

$$\varepsilon = \sqrt{\frac{2 \log \left(\frac{2N(d+1)}{\delta}\right)}{\delta}},$$

13
one can obtain
\[
P \left( \max_{k \in [N]} \{ \| \hat{a}_k^0 \|, \| w_k^0 \|_\infty \} > \varepsilon \right) = P \left( \left( \bigcup_{k \in [N]} \{ \| \hat{a}_k^0 \| > \varepsilon \} \right) \bigcup \left( \bigcup_{k \in [N], \alpha \in [d]} \{ |(w_k^0)_\alpha| > \varepsilon \} \right) \right)
\leq \sum_{k=1}^N P (\| \hat{a}_k^0 \| > \varepsilon) + \sum_{k=1}^N \sum_{\alpha=1}^d P (|(w_k^0)_\alpha| > \varepsilon)
\leq 2Ne^{-\frac{1}{2}\varepsilon^2} + 2Ne^{-\frac{1}{2}\varepsilon^2}
= 2N(d + 1)e^{-\frac{1}{2}\varepsilon^2}
= \delta,
\]
which implies the conclusions of this lemma. \qed

**Lemma 4.2.** For any \( \delta \in (0, 1) \) with probability at least \( 1 - \delta \) over the random initialization in (4.1), we have
\[
R_S(\theta^0) \leq \frac{1}{2} \left( 1 + 32\gamma \sqrt{N}Md^3 \left( \log \frac{4N(d + 1)}{\delta} \right)^2 \left( \sqrt{2 \log(2d)} + \sqrt{2 \log(8/\delta)} \right) \right)^2,
\]
where
\[
\mathcal{H} = \{ h(\bar{a}, w; x) \mid h(\bar{a}, w; x) = \bar{a} \left[ w^\top A(x) w \sigma''(w^\top x) + b^\top(x) w \sigma'(w^\top x) + c(x) \sigma(w^\top x) \right], x \in \Omega \}.
\]

**Proof.** From Lemma 4.1 we know that with probability at least \( 1 - \delta/2 \),
\[
|a_k^0| \leq \sqrt{2 \log \frac{4N(d + 1)}{\delta}} \quad \text{and} \quad \| w_k^0 \|_1 \leq d \sqrt{2 \log \frac{4N(d + 1)}{\delta}}.
\]
Note that \( A, b, \) and \( c \) are known functions of \( x \). Each element in the above set is a function of \( \bar{a} \) and \( w \) while \( x \in \Omega = [0, 1]^d \) is a parameter. Since \( \| x \|_\infty \leq 1 \), we have
\[
|h(\bar{a}_k^0, w_k^0; x)| \leq |a_k^0| \left[ M \| w_k^0 \|_1^3 + \frac{1}{2} M \| w_k^0 \|_1^3 + \frac{1}{6} M \| w_k^0 \|_1^3 \right]
\leq 2M |a_k^0| \| w_k^0 \|_1^3
\leq 8Md^3 \left( \log \frac{4N(d + 1)}{\delta} \right)^2.
\]
Then with probability at least \( 1 - \delta/2 \), we have
\[
\frac{1}{\gamma N} \sup_{x \in \Omega} |f_{\theta^0}(x)| = \sup_{x \in \Omega} \left| \frac{1}{N} \sum_{k=1}^N h(\bar{a}_k^0, w_k^0; x) - E(\bar{a}, w) \sim N(0, I_{d+1}) h(\bar{a}, w; x) \right|
\leq 2Rad_{\theta^0}(\mathcal{H}) + 24Md^3 \left( \log \frac{4N(d + 1)}{\delta} \right)^2 \sqrt{\frac{2 \log(8/\delta)}{N}}.
\]
where

\[
\text{Rad}_\delta(H) := \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k h(a_k, w_k; x) \right] \leq I_1 + I_2 + I_3,
\]

\[
I_1 = \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k w_k^\top A(x) w_k \sigma''(w_k^\top x) \right],
\]

\[
I_2 = \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k b'(x) w_k \sigma'(w_k^\top x) \right],
\]

\[
I_3 = \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k c(x) \sigma(w_k^\top x) \right],
\]

where \( \tau \) is a random vector in \( \mathbb{N}^N \) with i.i.d. entries \( \{\tau_k\}_{k=1}^N \) following the Rademacher distribution.

We only prove for \( I_1 \). It can be straightforwardly extended to \( I_2 \) and \( I_3 \).

\[
I_1 = \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k w_k^\top A(x) w_k \sigma''(w_k^\top x) \right]
\leq \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x, y \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k w_k^\top A(y) w_k \sigma''(w_k^\top x) \right]
= \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x, y \in \Omega} \sum_{k=1}^{N} \sum_{\alpha, \beta = 1}^{d} \tau_k \bar{a}_k (w_k^\top)_{\alpha} A_{\alpha \beta}(y) (w_k)_{\beta} \sigma''(w_k^\top x) \right]
\leq \sum_{\alpha, \beta = 1}^{d} \frac{1}{N} \mathbb{E}_\tau \left[ \sup_{x, y \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k (w_k^\top)_{\alpha} A_{\alpha \beta}(y) (w_k)_{\beta} \sigma''(w_k^\top x) \right],
\]

(4.7)

For any \( \alpha, \beta \in [d] \), we have

\[
\mathbb{E}_\tau \left[ \sup_{x, y \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k (w_k^\top)_{\alpha} A_{\alpha \beta}(y) (w_k)_{\beta} \sigma''(w_k^\top x) \right]
\leq \mathbb{E}_\tau \left[ \sup_{x, y \in \Omega} |A_{\alpha \beta}(y)| \sum_{k=1}^{N} \tau_k \bar{a}_k (w_k^\top)_{\alpha} (w_k)_{\beta} \sigma''(w_k^\top x) \right]
\leq ME_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k (w_k^\top)_{\alpha} (w_k)_{\beta} \sigma''(w_k^\top x) \right]
\leq ME_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k (w_k^\top)_{\alpha} (w_k)_{\beta} \sigma''(w_k^\top x) \right] + ME_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} -\tau_k \bar{a}_k (w_k^\top)_{\alpha} (w_k)_{\beta} \sigma''(w_k^\top x) \right]
\leq 2ME_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \bar{a}_k (w_k^\top)_{\alpha} (w_k)_{\beta} \sigma''(w_k^\top x) \right],
\]

(4.8)

where in the third inequality, we have used the fact that \( \sigma''(w_k^\top x) = 0 \) for \( x = 0 \) and for any \( w_k \). Applying Lemma 5.1 with \( \psi_k(y_k) = \bar{a}_k (w_k^\top)_{\alpha} (w_k)_{\beta} \sigma''(y_k) \), \( k \in [N] \) whose Lipschitz constant is

15
\[
\left(\sqrt{2\log \frac{4N(d+1)}{\delta}}\right)^3, \text{ we have for all } \alpha, \beta \in [d]
\]
\[
\mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k \dot{a}_k(w_k) \sigma''(w_k^\top x) \right] \leq \left(\sqrt{2\log \frac{4N(d+1)}{\delta}}\right)^3 \mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k w_k^\top x \right]. \tag{4.9}
\]

Therefore, combining (4.7), (4.8), and (4.9), we obtain
\[
I_1 \leq \frac{2Md^2}{N} \left(\sqrt{2\log \frac{4N(d+1)}{\delta}}\right)^3 \mathbb{E}_\tau \left[ \sup_{x \in \Omega} \sum_{k=1}^{N} \tau_k w_k^\top x \right]
\]
\[
\leq \frac{2Md^2}{\sqrt{N}} \left(\sqrt{2\log \frac{4N(d+1)}{\delta}}\right)^4 \sqrt{2\log(2d)}
\]
\[
\leq \frac{8Md^2\sqrt{2\log(2d)}}{\sqrt{N}} \left(\log \frac{4N(d+1)}{\delta}\right)^2.
\]

For \(I_2\) and \(I_3\), we note that \(\sigma(z) = \frac{1}{6}z^2\sigma''(z)\) and \(\sigma'(z) = \frac{1}{2}z\sigma''(z)\). Then by the similar argument, we have
\[
I_2 \leq \frac{4Md \sqrt{2\log(2d)}}{\sqrt{N}} \left(\log \frac{4N(d+1)}{\delta}\right)^2,
\]
\[
I_3 \leq \frac{4M \sqrt{2\log(2d)}}{3\sqrt{N}} \left(\log \frac{4N(d+1)}{\delta}\right)^2,
\]
\[
\text{Rad}_{\theta_0}(\mathcal{H}) \leq \frac{16Md^2\sqrt{2\log(2d)}}{\sqrt{N}} \left(\log \frac{4N(d+1)}{\delta}\right)^2.
\]

So one can get
\[
\sup_{x \in \Omega} |f_{\theta_0}(x)| \leq \frac{32\gamma Md^2}{\sqrt{N}} \sqrt{2\log(2d)} \left(\log \frac{4N(d+1)}{\delta}\right)^2 + 24\gamma \sqrt{N} Md^3 \left(\log \frac{4N(d+1)}{\delta}\right)^2 \sqrt{2\log(8/\delta)}
\]
\[
\leq 32\gamma \sqrt{N} Md^3 \left(\log \frac{4N(d+1)}{\delta}\right)^2 \left(\sqrt{2\log(2d)} + \sqrt{2\log(8/\delta)}\right).
\]

Then
\[
R_S(\theta_0) \leq \frac{1}{2n} \sum_{i=1}^{n} (1 + |f_{\theta_0}(x_i)|)^2
\]
\[
\leq \frac{1}{2} \left(1 + 32\gamma \sqrt{N} Md^3 \left(\log \frac{4N(d+1)}{\delta}\right)^2 \left(\sqrt{2\log(2d)} + \sqrt{2\log(8/\delta)}\right)^2 \right).
\]

The following lemma shows the positive definiteness of \(G^{(a)}\) at initialization.

**Lemma 4.3.** For any \(\delta \in (0, 1)\) if \(N \geq \frac{256nM^4C_d}{\lambda_S^2\delta} \) then with probability at least \(1 - \delta\) over the random initialization in (4.1), we have
\[
\lambda_{\min} \left(G^{(a)}(\theta_0)\right) \geq \frac{3}{4} \lambda_S.
\]
where \(C_d := \mathbb{E}||w||_1^2 < +\infty\) with \(w \sim \mathcal{N}(0, I_d)\).

16
Proof. We define $\Omega_{ij} := \{ \theta^0 \mid |G_{ij}^{(a)}(\theta^0) - K_{ij}^{(a)}| \leq \frac{\lambda_S}{4n} \}$. Note that

$$|g^{(a)}(w_k; x_i, x_j)| \leq \left( M\|w_k\|^3_1 + \frac{1}{2}M\|w_k\|^3_1 + \frac{1}{6}M\|w_k\|^3_1 \right)^2 \leq 4M^2\|w_k\|_1^6.$$  

So

$$\text{Var} \left(g^{(a)}(w_k; x_i, x_j) \right) \leq \mathbb{E} \left(g^{(a)}(w_k; x_i, x_j) \right)^2 \leq 16M^4\mathbb{E}\|w_k\|_1^2 = 16M^4C_d,$$

and

$$\text{Var} \left(G_{ij}^{(a)}(\theta^0) \right) = \frac{1}{N^2} \sum_{k=1}^{N} \text{Var} \left(g^{(a)}(w_k; x_i, x_j) \right) \leq \frac{16M^4C_d}{N}.$$  

Then the probability of the event $\Omega_{ij}$ has the lower bound:

$$\mathbb{P}(\Omega_{ij}) \geq 1 - \frac{\text{Var} \left(G_{ij}^{(a)}(\theta^0) \right)}{[\lambda_S/(4n)]^2} \geq 1 - \frac{256M^4n^2C_d}{\lambda_S^2N^2}.$$  

Thus, with probability at least $\left(1 - \frac{256M^4n^2C_d}{\lambda_S^2N^2} \right)^n \geq 1 - \frac{256M^4n^2C_d}{\lambda_S^2N^2}$, we have all events $\Omega_{ij}$, $i,j \in [n]$ happen. This implies that with probability at least $1 - \frac{256M^4n^2C_d}{\lambda_S^2N^2}$, we have

$$\|G^{(a)}(\theta^0) - K^{(a)}\|_F \leq \frac{\lambda_S}{4}$$

and

$$\lambda_{\min} \left(G^{(a)}(\theta^0) \right) \geq \lambda_S - \|G^{(a)}(\theta^0) - K^{(a)}\|_F \geq \frac{3}{4}\lambda_S.$$  

For any $\delta \in (0, 1)$, if $N \geq \frac{256n^4M^4C_d}{\lambda_S^2\delta}$, then with probability at least $1 - \frac{256M^4n^2C_d}{\lambda_S^2N^2} \geq 1 - \delta$ over the initialization $\theta^0$, we have $\lambda_{\min} \left(G^{(a)}(\theta^0) \right) \geq \frac{3}{4}\lambda_S$. \hfill \qed

The following lemma estimates the empirical loss dynamics before the stopping time $t^*$ in [4.5].

Lemma 4.4. For any $\delta \in (0, 1)$, if $N \geq \frac{256n^4M^4C_d}{\lambda_S^2\delta}$, then with probability at least $1 - \delta$ over the random initialization in [1.1], we have for any $t \in [0, t^*)$

$$R_S(\theta(t)) \leq \exp \left(-\frac{N\lambda_S t}{n} \right) R_S(\theta^0).$$

Proof. From Lemma 4.3, for any $\delta \in (0, 1)$ with probability at least $1 - \delta$ over initialization $\theta^0$ and for any $t \in [0, t^*)$, we have $\theta(t) \in \mathcal{M}(\theta^0)$ and

$$\lambda_{\min} \left(G^{(a)}(\theta) \right) \geq \lambda_{\min} \left(G^{(a)}(\theta^0) \right) - \|G^{(a)}(\theta) - G^{(a)}(\theta^0)\|_F \geq \frac{3}{4}\lambda_S - \frac{1}{4}\lambda_S$$

$$= \frac{1}{2}\lambda_S.$$  

Note that $G_{ij} = \frac{1}{n} \nabla_{\theta}\theta_0(x_i) \cdot \nabla_{\theta}\theta_0(x_j)$ and $\nabla_{\theta}R_S = \frac{1}{n} \sum_{i=1}^{n} e_i \nabla_{\theta}\theta_0(x_i)$, so

$$\|\nabla_{\theta}R_S(\theta(t))\|_2^2 = \frac{N}{n^2} e^T G(\theta(t)) e \geq \frac{N}{n^2} e^T G^{(a)}(\theta(t)) e,$$
where the last equation is true by the fact that \( G^{(w)}(\theta(t)) \) is a Gram matrix and hence positive semi-definite. Together with

\[
\frac{N}{n^2} e^T G^{(a)}(\theta(t)) e \geq \frac{2N}{n} \lambda_{\min} \left( G^{(a)}(\theta(t)) \right) \quad R_S(\theta(t)) \geq \frac{N}{n} \lambda_S R_S(\theta(t)),
\]

then finally we get

\[
\frac{d}{dt} R_S(\theta(t)) = -\|\nabla_\theta R_S(\theta(t))\|^2 \leq -\frac{N}{n} \lambda_S R_S(\theta(t)).
\]

Integrating the above equation yields the conclusion in this lemma. \(\square\)

**Lemma 4.5.** For any \( \delta \in (0, 1) \) if \( N \geq \max \left\{ \frac{512n^2M^4C_d}{\lambda_S^2 \delta}, \frac{200\sqrt{2Md^3n \log(4N(d+1)/\delta)} \sqrt{R_S(\theta^0)}}{\lambda_S} \right\} \) then with probability at least \( 1 - \delta \) over the random initialization in [4,1], for any \( t \in [0, t^*) \) and any \( k \in [N] \),

\[
|a_k(t) - a_k(0)| \leq q, \quad \|w_k(t) - w_k(0)\|_\infty \leq q,
\]

\[
|a_k(0)| \leq \sqrt{2\log \frac{4N(d+1)}{\delta}}, \quad \|w_k(0)\|_\infty \leq \sqrt{2\log \frac{4N(d+1)}{\delta}},
\]

where

\[
q := \frac{320Md^3(\log \frac{4N(d+1)}{\delta})^{3/2} n \sqrt{R_S(\theta^0)}}{N\lambda_S}.
\]

**Proof.** Let \( \xi(t) = \max_{k \in [N], s \in [0, t]} \{ |a_k(s)|, \|w_k(s)\|_\infty \} \). Note that

\[
|\nabla_{a_k} R_S| = \left\{ 1 + \sum_{i=1}^n e_i \left[ w_k^T A(x_i) w_k \sigma''(w_k^T x_i) + b^T(x_i) w_k \sigma'(w_k^T x_i) + c(x_i) \sigma(w_k^T x_i) \right] \right\}^2 
\]

\[
\leq 8M^2 \|w_k\|_s^6 R_S(\theta)
\]

\[
\leq 8M^2 d^6(\xi(t))^6 R_S(\theta),
\]

and

\[
|\nabla_{w_k} R_S|_\infty^2 = \left\| \frac{1}{n} \sum_{i=1}^n e_i a_k \left[ 2A(x_i) w_k \sigma''(w_k^T x_i) + w_k^T A(x_i) w_k \sigma'''(w_k^T x_i) x_i + \sigma'(w_k^T x_i) b(x_i) + b^T(x_i) w_k \sigma''(w_k^T x_i) x_i + c(x_i) \sigma'(w_k^T x_i) x_i \right] \right\|_\infty^2
\]

\[
\leq \|a_k\|^2 2RS(\theta) \left( 2M \|w_k\|_s^2 + M \|w_k\|_s^4 + \frac{1}{2} M \|w_k\|_s^2 + M \|w_k\|_s^4 + M \frac{1}{2} \|w_k\|_s^2 \right)^2
\]

\[
\leq 50M^2 \|w_k\|_s^4 |a_k|^2 R_S(\theta)
\]

\[
\leq 50M^2 d^4 (\xi(t))^6 R_S(\theta).
\]

18
From Lemma 4.4 if \( N \geq \frac{512 M^3 n^4 C_d}{\lambda_S^3} \), then with probability at least \( 1 - \delta/2 \) over initialization

\[
|a_k(t) - a_k(0)| \leq \int_0^t |\nabla a_k R_S(\theta(s))| ds
\]

\[
\leq 2\sqrt{2}Md^3 \int_0^t \xi^3(t) \sqrt{R_S(\theta(s))} ds
\]

\[
\leq 2\sqrt{2}Md^3 \xi^3(t) \int_0^t \sqrt{R_S(\theta^0)} \exp \left( -\frac{N\lambda_S s}{2n} \right) ds
\]

\[
\leq \frac{4\sqrt{2}Md^3 n \sqrt{R_S(\theta^0)}}{N\lambda_S} \xi^3(t)
\]

\[
\leq p\xi^3(t),
\]

where \( p := \frac{10\sqrt{2}d^3 M n \sqrt{R_S(\theta^0)}}{N\lambda_S} \). Similarly,

\[
\|w_k(t) - w_k(0)\|_\infty \leq \int_0^t \|\nabla w_k R_S(\theta(s))\|_\infty ds
\]

\[
\leq 5\sqrt{2}Md^2 \int_0^t \xi^3(t) \sqrt{R_S(\theta(s))} ds
\]

\[
\leq 5\sqrt{2}Md^2 \xi^3(t) \int_0^t \sqrt{R_S(\theta^0)} \exp \left( -\frac{N\lambda_S s}{2n} \right) ds
\]

\[
\leq \frac{10\sqrt{2}Md^2 n \sqrt{R_S(\theta^0)}}{N\lambda_S} \xi^3(t)
\]

\[
\leq p\xi^3(t).
\]

So

\[
\xi(t) \leq \xi(0) + p\xi^3(t).
\]

From Lemma 4.1 with probability at least \( 1 - \delta/2 \),

\[
\xi(0) = \max_{k \in [N]} \{ |a_k(0)|, \|w_k(0)\|_\infty \} \leq \max \left\{ \gamma \frac{\log 4N(d+1)}{\delta}, \sqrt{2\log \frac{4N(d+1)}{\delta}} \right\} \tag{4.10}
\]

\[
\leq \sqrt{2\log \frac{4N(d+1)}{\delta}} =: \eta. \tag{4.11}
\]

Let

\[
t_0 := \inf\{ t \mid \xi(t) > 2\eta \}.
\]

Suppose that \( t_0 < t^* \). Since

\[
N \geq \frac{200 \sqrt{2}Md^3 n \log(4N(d+1)/\delta) \sqrt{R_S(\theta^0)}}{\lambda_S} = 10N p \eta^2,
\]

then \( p \leq \frac{1}{10} \left( 2 \log \frac{4N(d+1)}{\delta} \right)^{-1} = \frac{1}{10} \eta^{-2} \). For \( t \in [0, t_0) \),

\[
\xi(t) \leq \eta + p(2n)^2 \xi(t) \leq \eta + \frac{2}{5} \xi(t),
\]

\[
\leq \eta + p\xi^3(t) \leq \eta.
\]
Finally notice
\[ \xi(t) \leq \frac{5}{3} \eta, \]
after letting \( t \to t_0 \), this contradicts with the definition of \( t_0 \). So \( t_0 \geq t^* \) and then \( \xi(t) \leq 2\eta \) for all \( t \in [0, t^*) \). Thus
\[ |a_k(t) - a_k(0)| \leq 8\eta^3 \rho \]
\[ \|w_k(t) - w_k(0)\|_\infty \leq 8\eta^3 \rho. \]

Finally notice
\[ 8\eta^3 \rho = 8\sqrt{8} \left( \log \frac{4N(d+1)}{\delta} \right)^{3/2} \frac{10\sqrt{2Md^3n\sqrt{R_S(\theta)}}}{N\lambda_S} \]
\[ = \frac{320Md^3 \left( \log \frac{4N(d+1)}{\delta} \right)^{3/2}}{N\lambda_S} n\sqrt{R_S(\theta)} \]
\[ = q. \]
which ends the proof. \qed

4.3 Proof of Theorem 3.1

Proof of Theorem 3.1 From Lemma 4.4 it is sufficient to prove that the stopping time \( t^* \) in Lemma 4.3 is equal to \( +\infty \). We will prove this by contradiction.

Suppose \( t^* < +\infty \). Note that
\[ |G_{ij}^{(a)}(\theta(t^*)) - G_{ij}^{(a)}(\theta(0))| \leq \frac{1}{N} \sum_{k=1}^N |g(w_k(t^*); x_i, x_j) - g(w_k(0); x_i, x_j)|. \]
(4.13)

By the mean value theorem,
\[ |g(w_k(t^*); x_i, x_j) - g(w_k(0); x_i, x_j)| \leq \|\nabla g(cw_k(t^*) + (1-c)w_k(0); x_i, x_j)\|_\infty \|w_k(t^*) - w_k(0)\|_1 \]
for some \( c \in (0,1) \). Further computation yields
\[ \nabla g(w; x_i, x_j) = \left[ 2A(x_i)w\sigma''(w^T x_i) + w^T A(x_i)w\sigma^{(3)}(w^T x_i)x_i + \sigma'(w^T x_i)b(x_i) \right. \]
\[ + b^T(x_i)w\sigma''(w^T x_i)x_i + c(x_i)\sigma'(w^T x_i)x_i \]
\[ \left. \times \left[ w^TA(x_j)w\sigma''(w^T x_j) + b^T(x_j)w\sigma'(w^T x_j) + c(x_j)\sigma(w^T x_j) \right] \right) \]
\[ + \left[ 2A(x_j)w\sigma''(w^T x_j) + w^T A(x_j)w\sigma^{(3)}(w^T x_j)x_j + \sigma'(w^T x_i)b(x_i) \right. \]
\[ + b^T(x_j)w\sigma''(w^T x_j)x_j + c(x_j)\sigma'(w^T x_j)x_j \]
\[ \left. \times \left[ w^TA(x_i)w\sigma''(w^T x_i) + b^T(x_i)w\sigma'(w^T x_i) + c(x_i)\sigma(w^T x_i) \right] \right) \]
for all \( w \). Hence, it holds for all \( w \) that
\[ \|\nabla g(w; x_i, x_j)\|_\infty \leq 2 \left[ 2M\|w\|^2 + M\|w\|^2 + \frac{1}{2}M\|w\|^2 + M\|w\|^2 + \frac{1}{2}M\|w\|^2 \right] \]
\[ \times \left[ M\|w\|^2 + \frac{1}{2}M\|w\|^2 + \frac{1}{6}M\|w\|^3 \right] \]
\[ \leq 2(5M\|w\|^2)(2M\|w\|^3) \]
\[ = 20M^2\|w\|^5. \]
Therefore, the bound in (4.13) becomes
\[ |G_{ij}^{(a)}(\theta(t^*)) - G_{ij}^{(a)}(\theta(0))| \leq \frac{20M^2}{N} \sum_{k=1}^{N} \|cw_k(t^*) + (1-c)w_k(0)\|_1 \|w_k(t^*) - w_k(0)\|_1. \] (4.14)

By Lemma 4.5,
\[ \|cw_k(t^*) + (1-c)w_k(0)\|_1 \leq \|w_k(0)\|_1 + \|w_k(t^*) - w_k(0)\|_1 \leq d(\eta + q) \leq 2d\eta, \]
where \( \eta = \sqrt{2 \log \frac{4N(d+1)}{\delta}} \) and \( q \) is defined in (4.12). So, (4.14) and the above inequalities indicate
\[ |G_{ij}^{(a)}(\theta(t^*)) - G_{ij}^{(a)}(\theta(0))| \leq 20M^2(2d\eta)^5dq = 640M^2d^5\eta^5q, \]
and
\[ \|G^{(a)}(\theta(t^*)) - G^{(a)}(\theta(0))\|_F \leq \frac{640M^2d^5\eta^5q}{\lambda_S} \leq \frac{1}{4}\lambda_S, \]
if we choose
\[ N \geq \frac{2^{23}M^3d^9n^2(\log(4N(d+1)/\delta))4}{\lambda_S^2}\sqrt{R_S(\theta^0)}. \]
The fact that \( \|G^{(a)}(\theta(t^*)) - G^{(a)}(\theta(0))\|_F \leq \frac{1}{4}\lambda_S \) contradicts with the definition of \( t^* \) in (4.5). Hence, we have completed the proof. \( \Box \)

5 A priori Estimates of Generalization Error for Two-layer Neural Networks

To obtain good generalization, instead of minimizing \( R_S \), we minimize the regularized risk of \( R_S(\theta) \):
\[ J_{S,\lambda}(\theta) := R_S(\theta) + \frac{\lambda}{\sqrt{n}}||\theta||_F^2 \] (5.1)
to obtain
\[ \theta_{S,\lambda} = \arg \min_{\theta} J_{S,\lambda}(\theta). \] (5.2)

Here the path norm is defined in Definition 2.2. We will show that the PDE solution network \( \phi(x; \theta_{S,\lambda}) \) generalize well if the true solution is in the Barron-type space. The generalization error is measured in terms of how well \( f(x; \theta_{S,\lambda}) \) generalizes from the random training samples \( S = \{x_i\}_{i=1}^n \subset \Omega \) to arbitrary samples in \( \Omega \).

Recall that \( f(x; \theta) \), also denoted as \( f_\theta(x) \), is the result of the differential operator \( \mathcal{L} \) acting on a two-layer neural network \( \phi(x; \theta) \) in the domain \( \Omega \). In fact, \( f(x; \theta) \) is also a two-layer neural network as explained in (1.2). Hence, the generalization error analysis of deep learning-based PDE solvers is reduced to the generalization analysis of the special two-layer neural network \( f(x; \theta) \) fitting \( f(x) \). The special structure of \( f(x; \theta) \) leads to significant difficulty in analyzing the generalization error compared to traditional two-layer neural networks in the literature.

We will first summarize and prove several lemmas related to Rademacher complexity in Section 5.1. The proofs of our main theorems for the generalization bound in Theorems 5.2 and 5.3 are presented in Section 5.2.
5.1 Preliminary lemmas of Rademacher complexity

First, we define the set of functions $F = \{ f(x; \theta) \mid \| \theta \|_p \leq Q \}$ and recall a well-known contraction lemma for the Rademacher complexity.

**Lemma 5.1** (Contraction lemma [37]). Suppose that $\psi_i : \mathbb{R} \to \mathbb{R}$ be a $C_L$-Lipschitz function for each $i \in [n]$. For any $y \in \mathbb{R}^n$, let $\psi(y) = (\psi_1(y_1), \ldots, \psi_n(y_n))^\top$, then we have

$$\text{Rad}_S(\psi \circ F) \leq C_L \text{Rad}_S(F).$$

Second, we estimate the Rademacher complexity of the class of the set of special two-layer neural networks $F_Q$.

**Lemma 5.2** (Rademacher complexity of two-layer neural networks). The Rademacher complexity of $F_Q$ over a set of $n$ uniform distributed random samples of $\Omega$ (denoted as $S$) has an upper bound

$$\text{Rad}_S(F_Q) \leq \frac{4MQd^2 \sqrt{2 \log(2d)}}{\sqrt{n}},$$

where $M$ is the upper bound of the differential operator $\mathcal{L}$ introduced in (3.1).

**Proof.** Let $\hat{w}_k = w_k/\|w_k\|_1$ for $k = 1, \ldots, N$ and $\tau$ be a random vector in $\mathbb{N}^d$ with i.i.d. entries following the Rademacher distribution. Then

$$n\text{Rad}_S(F_Q)$$

$$= \mathbb{E}_\tau \left\{ \sup_{\| \theta \|_p \leq Q} \sum_{i=1}^n \sum_{k=1}^N \tau_i a_k [w_k^\top A(x_i)w_k \sigma''(w_k^\top x_i) + b^\top(x_i)w_k \sigma'(w_k^\top x_i) + c(x_i)\sigma(w_k^\top x_i)] \right\}$$

$$\leq \mathbb{E}_\tau \left[ \sup_{\| \theta \|_p \leq Q} \sum_{i=1}^n \sum_{k=1}^N \tau_i a_k w_k^\top A(x_i)w_k \sigma''(w_k^\top x_i) \right] + \mathbb{E}_\tau \left[ \sup_{\| \theta \|_p \leq Q} \sum_{i=1}^n \sum_{k=1}^N \tau_i a_k b^\top(x_i)w_k \sigma'(w_k^\top x_i) \right]$$

$$+ \mathbb{E}_\tau \left[ \sup_{\| \theta \|_p \leq Q} \sum_{i=1}^n \sum_{k=1}^N \tau_i a_k c(x_i)\sigma(w_k^\top x_i) \right]$$

$$=: I_1 + I_2 + I_3. \quad (5.3)$$
We first estimate $I_1$ as follows

$$
I_1 = \mathbb{E}_\tau \left[ \sup_{\|\theta\| \leq Q} \sum_{i=1}^{n} \tau_i \sum_{k=1}^{N} a_k \|w_k\|_1^3 \hat{w}_k^\top A(x_i) \hat{w}_k \sigma''(\hat{w}_k^\top x_i) \right]
$$

$$
\leq \mathbb{E}_\tau \left[ \sup_{\|\theta\| \leq Q, \|u_k\|_1 = 1, \forall k} \sum_{i=1}^{n} \tau_i \sum_{k=1}^{N} a_k \|w_k\|_1^3 \|u_k\|_1^3 \hat{w}_k^\top A(x_i) u_k \sigma''(u_k^\top x_i) \right]
$$

$$
= \mathbb{E}_\tau \left[ \sup_{\|\theta\| \leq Q, \|u_k\|_1 = 1, \forall k} \sum_{k=1}^{N} a_k \|w_k\|_1^3 \sum_{i=1}^{n} \tau_i \hat{w}_k^\top A(x_i) u_k \sigma''(u_k^\top x_i) \right]
$$

$$
\leq Q \mathbb{E}_\tau \left[ \sup_{\|\theta\| \leq Q, \|u_k\|_1 = 1, \forall k} \sum_{i=1}^{n} \tau_i p^\top A(x_i) q \sigma''(u^\top x_i) \right]
$$

$$
= Q \mathbb{E}_\tau \left[ \sup_{\|\theta\| \leq Q, \|u_k\|_1 = 1, \forall k} \sum_{i=1}^{n} \tau_i p^\top A(x_i) \sigma''(u^\top x_i) \right]
$$

$$
= Q \mathbb{E}_\tau \left[ \sup_{\|\theta\| \leq Q, \|u_k\|_1 = 1, \forall k} \sum_{i=1}^{n} \tau_i A_{\alpha \beta}(x_i) \sigma''(u^\top x_i) \right]
$$

Note that $\sigma''(u^\top x_i) = 0$ for $u = 0$ and for any $x_i$. For any $\alpha, \beta \in [d]$, we have

$$
\mathbb{E}_\tau \left[ \sup_{\|u\|_1 \leq 1} \left| \sum_{i=1}^{n} \tau_i A_{\alpha \beta}(x_i) \sigma''(u^\top x_i) \right| \right] \leq \mathbb{E}_\tau \left[ \sup_{\|u\|_1 \leq 1} \left| \sum_{i=1}^{n} \tau_i A_{\alpha \beta}(x_i) \sigma''(u^\top x_i) \right| \right]
$$

$$
+ \mathbb{E}_\tau \left[ \sup_{\|u\|_1 \leq 1} \left| \sum_{i=1}^{n} -\tau_i A_{\alpha \beta}(x_i) \sigma''(u^\top x_i) \right| \right]
$$

$$
= 2 \mathbb{E}_\tau \left[ \sup_{\|u\|_1 \leq 1} \left| \sum_{i=1}^{n} \tau_i A_{\alpha \beta}(x_i) \sigma''(u^\top x_i) \right| \right].
$$

Applying Lemma 5.1 with $\psi_i(y_i) = A_{\alpha \beta}(x_i) \sigma''(y_i), i \in [n]$ whose Lipschitz constant is $M$, we have for all $\alpha, \beta \in [d]

$$
\mathbb{E}_\tau \left[ \sup_{\|u\|_1 \leq 1} \left| \sum_{i=1}^{n} \tau_i A_{\alpha \beta}(x_i) \sigma''(u^\top x_i) \right| \right] \leq M \mathbb{E}_\tau \left[ \sup_{\|u\|_1 \leq 1} \left| \sum_{i=1}^{n} \tau_i u_i^\top x_i \right| \right].
$$
Therefore, combining (5.4), (5.5), and (5.6), we obtain

\[ I_1 \leq 2MQd^2\mathbb{E}_\tau \left[ \sup_{\|u\|_1 \leq 1} \sum_{i=1}^n \tau_i u^\top x_i \right] \leq 2MQd^2\sqrt{n} \sqrt{2 \log(2d)}. \]

For \( I_2 \) and \( I_3 \), we note that \( \sigma(z) = \frac{1}{6}z^2\sigma''(z) \) and \( \sigma'(z) = \frac{1}{2}z\sigma''(z) \). Then by the similar argument, we have

\[ I_2 \leq MQd\sqrt{n}\sqrt{2 \log(2d)}, \]
\[ I_3 \leq \frac{1}{3}MQ\sqrt{n}\sqrt{2 \log(2d)}. \]

These estimates for \( I_1, I_2, I_3 \) combined with (5.3) completes the proof.

Finally, let us quote a general theorem concerning the Rademacher complexity and generalization gap of an arbitrary set of functions \( \mathcal{F} \) on an arbitrary domain \( \mathcal{Z} \) \[37\].

**Theorem 5.1** (Rademacher complexity and generalization gap \[37\]). Suppose that \( f \)'s in \( \mathcal{F} \) are non-negative and uniformly bounded, i.e., for any \( f \in \mathcal{F} \) and any \( z \in \mathcal{Z} \), \( 0 \leq f(z) \leq B \). Then for any \( \delta \in (0, 1) \), with probability at least \( 1 - \delta \) over the choice of samples \( S = \{z_1, \ldots, z_n\} \subset \mathcal{Z} \), we have

\[ \sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^n f(z_i) - \mathbb{E}_z f(z) \right| \leq 2\mathbb{E}_{S'}\text{Rad}_{S'}(\mathcal{F}) + B \sqrt{\frac{\log(2/\delta)}{2n}}, \]

where the dummy variable \( S' \) denotes a set of \( n \) i.i.d. random samples of \( \mathcal{Z} \).

### 5.2 Proofs of generalization bounds

In the proofs of this section, we will first show in Proposition 5.1 below that two-layer neural networks \( f(x; \theta) \) in (4.2) can approximate Barron-type functions with an approximation error \( O(\|f\|_2^2 B_N) \). Second, for an arbitrary \( f(x; \theta) = L\phi(x; \theta) \), we show its a posteriori generalization bound \( |R_D(\theta) - R_S(\theta)| \leq O\left(\frac{\|\theta\|_3^2}{\sqrt{n}}\right) \) in Theorem 3.2. Finally, the a priori generalization bound \( R_D(\theta_{S, \lambda}) \leq O\left(\frac{\|f\|_N^2}{N} + \frac{\|f\|_3^2}{\sqrt{n}}\right) \) is proved in Theorem 3.3 where the first and second terms come from the approximation error bound and the a posteriori generalization bound.

First, the approximation capacity of two-layer neural networks \( f(x; \theta) \) can be characterized by Proposition 5.1 below.

**Proposition 5.1** (Approximation Error). For any \( f \in \mathcal{B}(\Omega) \), there exists a two-layer neural network \( f(x; \hat{\theta}) \) of width \( N \) with \( \|\hat{\theta}\|_P \leq 2\|f\|_B \),

\[ R_D(\hat{\theta}) := \mathbb{E}_{x \sim \mathcal{D}} \frac{1}{2}(f(x, \hat{\theta}) - f(x))^2 \leq \frac{6M^2\|f\|_2^2}{N}, \]

where \( M \) introduced in (3.1) controls the upper bound of the differential operator and \( N \) is the width of the neural network.
Proof. Without loss of generality, let $\rho$ be the best representation, i.e., \( \|f\|_B^2 = \mathbb{E}_{(a,w) \sim \rho} |a| \|w\|_1^2 \). We set $\theta = \{(1/N) a_k, w_k\}_{k=1}^N$, where $(a_k, w_k)$, $k = 1, \cdots, N$ are independent sampled from $\rho$. Let

$$f_\theta(x) = \frac{1}{N} \sum_{k=1}^N a_k [w_k^\top A(x) w_k \sigma''(w_k^\top x) + b \top(x) w_k \sigma'(w_k^\top x) + c(x) \sigma(w_k^\top x)].$$

Recall the definition $R_D(\theta) = \mathbb{E}_{x \sim D} \frac{1}{2} \|f_\theta(x) - f(x)\|^2$. Then

\[
2 \mathbb{E}_{\theta} R_D(\theta) = \mathbb{E}_{x \sim D} \mathbb{E}_{\theta} \|f_\theta(x) - f(x)\|^2
= \mathbb{E}_{x \sim D} \text{Var}_{\{(a_k, w_k)\}_{i.i.d.} \sim \rho} \left( \frac{1}{N} \sum_{k=1}^N a_k [w_k^\top A(x) w_k \sigma''(w_k^\top x) + b \top(x) w_k \sigma'(w_k^\top x) + c(x) \sigma(w_k^\top x)] \right)
= \mathbb{E}_{x \sim D} \frac{1}{N} \text{Var}_{(a,w) \sim \rho} \left( a [w^\top A(x) w \sigma''(w^\top x) + b \top(x) w \sigma'(w^\top x) + c(x) \sigma(w^\top x)] \right)
\leq \frac{1}{N} \mathbb{E}_{x \sim D} \mathbb{E}_{(a,w) \sim \rho} \left( a [w^\top A(x) w \sigma''(w^\top x) + b \top(x) w \sigma'(w^\top x) + c(x) \sigma(w^\top x)] \right)^2
\leq \frac{1}{N} \mathbb{E}_{x \sim D} \mathbb{E}_{(a,w) \sim \rho} |a|^2 \left( M \|w\|_3^3 + \frac{1}{2} M \|w\|_1^3 + \frac{1}{6} M \|w\|_1^3 \right)^2
\leq \frac{4M^2}{N} \mathbb{E}_{(a,w) \sim \rho} |a|^2 \|w\|_1^6
= \frac{4M^2 \|f\|_B^2}{N}.
\]

Also, we have

$$\mathbb{E}_{\theta} \|\theta\|_p = \mathbb{E}_{\{(a_k, w_k)\}_{i.i.d.} \sim \rho} \frac{1}{N} \sum_{k=1}^N a_k \|w_k\|_1^3
= \mathbb{E}_{(a,w) \sim \rho} |a| \|w\|_1^3
\leq \|f\|_B.$$

Define two events $E_1 := \{R_D(\theta) < \frac{6M^2 \|f\|_B^2}{N}\}$ and $E_2 := \{\|\theta\|_p < 2 \|f\|_B\}$. By Markov inequality, we have

$$\mathbb{P}(E_1) = 1 - \mathbb{P} \left( R_D(\theta) \geq \frac{6M^2 \|f\|_B^2}{N} \right) \geq 1 - \frac{\mathbb{E}_{\theta} R_D(\theta)}{6M^2 \|f\|_B^2 / N} \geq \frac{2}{3},$$

\[
\mathbb{P}(E_2) = 1 - \mathbb{P}(\|\theta\|_p \geq 2 \|f\|_B) \geq 1 - \frac{\mathbb{E}_{\theta} \|\theta\|_p}{2 \|f\|_B} \geq \frac{1}{2}.
\]

Thus

$$\mathbb{P}(E_1 \cap E_2) \geq \mathbb{P}(E_1) + \mathbb{P}(E_2) - 1 \geq \frac{2}{3} + \frac{1}{2} - 1 > 0.$$

\[
\Box
\]

Second, we use Theorem 5.1 with $\mathcal{F} = \mathcal{F}_Q$ and $\mathcal{Z} = \Omega$ to show the a posteriori generalization bound in Theorem 3.2.
Proof of Theorem 3.2. Let \( \mathcal{H} = \bigcup_{Q=1}^{\infty} \mathcal{H}_Q \) with \( \mathcal{H}_Q := \{ \ell(f(x), f_{\theta}(x)) \mid \|\theta\|_P \leq Q \} \). Let \( \delta_Q = \frac{6\delta}{\pi MQ} \). Obviously, we have \( \sum_{Q=1}^{\infty} \delta_Q = \delta \). Note that \( \ell(\cdot, y) \) is a 1-Lipschitz function for all \( y \in \mathbb{R} \) and that

\[
\sup_{x \in \Omega} |f_{\theta}(x)| = \sum_{k=1}^{N} a_k |w_k^T A(x)w_k \sigma''(w_k^T x) + b^T(x)w_k \sigma'(w_k^T x) + c(x)\sigma(w_k^T x)|
\]

\[
\leq \sum_{k=1}^{N} |a_k| w_k \Vert^3 \left[ M + \frac{1}{2} M + \frac{1}{6} M \right]
\]

\[
\leq \frac{5}{3} M \|\theta\|_P.
\]

Therefore, for functions in \( \mathcal{H}_Q \), we have

\[
0 \leq \ell(f(x), f_{\theta}(x)) \leq \frac{1}{2} (1 + |f_{\theta}(x)|)^2
\]

\[
\leq \frac{1}{2} \left( 1 + \frac{5}{3} M \|\theta\|_P \right)^2
\]

\[
\leq \frac{32}{9} M^2 Q^2 \leq 4 M^2 Q^2.
\]

for all \( x \in \Omega \) and all \( Q \geq 1 \). Let \( S' \) be an arbitrary set of \( n \) samples of \( \Omega \), then \( \text{Rad}_{S'}(\mathcal{H}_Q) \leq \text{Rad}_{S'}(\mathcal{F}_Q) \). By Lemma 5.2 and Theorem 5.1, for any \( \delta \) and any positive integer \( Q \) with probability at least \( 1 - \delta_Q \) over \( S \), we have

\[
\sup_{\|\theta\|_P \leq Q} |R_D(\theta) - R_S(\theta)| \leq 2 \mathbb{E}_{S'} \text{Rad}_{S'}(\mathcal{F}_Q) + 4 M^2 Q^2 \sqrt{\frac{\log(2/\delta_Q)}{2n}}
\]

\[
\leq 8MQd^2 \sqrt{\frac{2 \log(2d)}{n}} + 4M^2Q^2 \sqrt{\frac{\log(\pi^2Q^2/3\delta)}{2n}}.
\]

For any \( \theta \in \mathbb{R}^{N(d+1)} \), choose integer \( Q \) such that \( \|\theta\|_P \leq Q \leq \|\theta\|_P + 1 \). Then we have

\[
|R_D(\theta) - R_S(\theta)| \leq 8M(\|\theta\|_P + 1)d^2 \sqrt{\frac{2 \log(2d)}{n}} + 4M^2(\|\theta\|_P + 1)^2 \sqrt{\frac{\log(\pi^2/3\delta)}{2n}} + \frac{\log(\|\theta\|_P + 1)^2}{2n}
\]

\[
\leq 8M(\|\theta\|_P + 1)d^2 \sqrt{\frac{2 \log(2d)}{n}} + 4M^2(\|\theta\|_P + 1)^2 \sqrt{\frac{\log(\pi^2/3\delta)}{2n}} + 4M^2(\|\theta\|_P + 1)^2 \sqrt{\frac{\log(\pi^2/3\delta)}{2n}}
\]

\[
\leq \frac{(\|\theta\|_P + 1)^2}{\sqrt{n}} 2\sqrt{2} M^2 (4d^2 \sqrt{\log(2d)} + 1 + \sqrt{\log(\pi^2/3\delta)}),
\]

where we have used the facts that \( \sqrt{a+b} \leq \sqrt{a} + \sqrt{b} \) for \( a, b > 0 \) and that \( \log a \leq a \) for \( a \geq 1 \). \( \Box \)

Finally, based on the approximation bound in Proposition 5.1 and the a posteriori generalization bound in Theorem 3.2, we show the a priori generalization bound in Theorem 3.3.

Proof of Theorem 3.3. Note that

\[
R_D(\theta_{S,\lambda}) = R_D(\tilde{\theta}) + [R_D(\theta_{S,\lambda}) - J_{S,\lambda}(\theta_{S,\lambda})] + [J_{S,\lambda}(\theta_{S,\lambda}) - J_{S,\lambda}(\tilde{\theta})] + [J_{S,\lambda}(\tilde{\theta}) - R_D(\tilde{\theta})].
\]
By definition, $J_{S,\lambda}(\theta_{S,\lambda}) - J_{S,\lambda}(\tilde{\theta}) \leq 0$. By Proposition 5.1, there exists $\tilde{\theta}$ such that $R_D(\tilde{\theta}) \leq \frac{6M^2\|f\|_B^2}{N}$. By Theorem 3.2, we have with probability at least $1 - \delta/2$,

$$R_D(\theta_{S,\lambda}) - J_{S,\lambda}(\theta_{S,\lambda}) = R_D(\theta_{S,\lambda}) - R_S(\theta_{S,\lambda}) - \frac{\lambda}{\sqrt{n}}\|\theta_{S,\lambda}\|_P^3$$

$$\leq \frac{1}{\sqrt{n}}2\sqrt{2}M^2(\|\theta_{S,\lambda}\|_P + 1)^3(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)}) - \frac{\lambda}{\sqrt{n}}\|\theta_{S,\lambda}\|_P^3$$

$$\leq \frac{1}{\sqrt{n}}8\sqrt{2}M^2(\|\theta_{S,\lambda}\|_P^3 + 1)(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)}) - \frac{\lambda}{\sqrt{n}}\|\theta_{S,\lambda}\|_P^3$$

$$\leq \frac{1}{\sqrt{n}}8\sqrt{2}M^2(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)})$$

where we have used the facts that $(a + b)^3 \leq 4a^3 + 4b^3$ for all $a, b \geq 0$ and that $\lambda \geq 8\sqrt{2}M^2(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)})$ in the second and last inequalities, respectively. By Theorem 3.2 again, we have with probability at least $1 - \delta/2$,

$$J_{S,\lambda}(\tilde{\theta}) - R_D(\tilde{\theta}) \leq \frac{1}{\sqrt{n}}2\sqrt{2}M^2(\|\theta\|_P + 1)^3(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)}) + \frac{\lambda}{\sqrt{n}}\|\theta\|_P^3$$

$$\leq \frac{1}{\sqrt{n}}8\sqrt{2}M^2(\|\theta\|_P^3 + 1)(1 + 4d^2\sqrt{\log(2d)} + \sqrt{\log(2\pi^2/3\delta)}) + \frac{\lambda}{\sqrt{n}}\|\theta\|_P^3$$

Adding the above estimates together, the proof is completed by using Proposition 5.1 $\|\theta\|_P \leq 2\|f\|_B$. □

6 Conclusion

This paper provided theoretical justification of deep learning-based PDE solvers for linear PDES and two-layer neural networks. In particular, we show that gradient descent can identify a global minimizer of the optimization problem with a well-controlled generalization error in the overparameterization regime (i.e., the network width is sufficiently large). The generalization error of the gradient descent solution does not suffer from the curse of dimensionality if the solution is in the Barron space. The analysis here forms a systematic framework for analyzing deep learning-based PDE solvers and sheds lights in future work for the theoretical foundation of solving nonlinear PDEs using deeper neural networks.
