Abstract

In this work, we construct and derive a new class of exponentially fitted two-derivative diagonally implicit Runge–Kutta (EFTDDIRK) methods for the numerical solution of differential equations with oscillatory solutions. First, a general format of so-called modified two-derivative diagonally implicit Runge–Kutta methods (TDDIRK) is proposed. Their order conditions up to order six are derived by introducing a set of bi-coloured rooted trees and deriving new elementary weights. Next, we build exponential fitting conditions in order for these modified TDDIRK methods to treat oscillatory solutions, leading to EFTDDIRK methods. In particular, a family of 2-stage fourth-order, a fifth-order, and a 3-stage sixth-order EFTDDIRK schemes are derived. These can be considered as superconvergent methods. The stability and phase-lag analysis of the new methods are also investigated, leading to optimized fourth-order schemes, which turn out to be much more accurate and efficient than their non-optimized versions. Finally, we carry out numerical experiments on some oscillatory test problems. Our numerical results clearly demonstrate the accuracy and efficiency of the newly derived methods when compared with existing implicit Runge–Kutta methods and two-derivative methods.

1. Introduction

Oscillatory differential equations have often been used to model oscillatory phenomena in various fields of applied sciences such as celestial mechanics \[7\], molecular dynamics \[24\], quantum chemistry \[45\] and genetic regulatory genomics \[16\], to mention a few. This class of differential equations can be formulated as initial value problems of the general form

\[
y'(x) = f(y(x)), \quad y(x_0) = y_0.
\]  

Simulating such an oscillatory system (1.1) is not an easy task since it usually involves periodic or oscillating solutions. An extensive discussion on numerical analysis of (1.1) including oscillatory systems can be found in \[27\]. In particular, classical methods such as explicit Runge–Kutta schemes have their limitations (e.g., the lack of stability) in capturing the right behavior of oscillatory solutions. This forces them to use tiny time steps and thereby is inefficient. In this regard, standard methods such as implicit Runge–Kutta methods \[26\] or recent advanced methods such as exponential integrators (e.g., see \[28, 35, 36, 37, 40, 39\]) are preferable since they may offer A-stable property or much larger stability regions, meaning less restriction to stepsizes. Here, we focus on diagonally implicit Runge–Kutta (DIRK) methods (or sometimes referred to as semi-implicit Runge–Kutta methods) \[34\], among others, which have shown to be very attractive \[3\] over fully implicit methods in terms of computational efficiency. They were also designed for differential systems with eigenvalues on the imaginary axis where the phase errors (dispersion) and the numerical damping (dissipation) of the free oscillations in the numerical solution are small, see \[19\].

Motivated by the work of \[33\] which utilizes higher order derivatives to derive superconvergent (implicit) Runge–Kutta schemes (see also \[23, 53, 51, 52\]), a class of two-derivative Runge–Kutta (TDRK) methods for solving (1.1) was proposed in \[12\]. An advantage of these methods is that the number of algebraic order conditions is significantly reduced in comparison with the classical Runge–Kutta methods of the same order, thereby allowing the construction of high-order schemes with only a few stages. Following
this, implicit TDRK methods were derived in [13, 4], general linear TDRK methods were presented in [1, 2, 3, 11], and recently TDRK methods with optimal phase properties were constructed in [32]. In the case if a good estimate of frequency is known in advance, one can further improve the numerical solution of these methods by incorporating the exponential fitting idea [22, 8, 29, 15] in order to integrate exactly the system whose solutions are linear combinations of $e^{\pm i\omega x}$ ($\omega$ is a prescribed frequency). This leads to exponentially/trigonometrically fitted two-derivative (EFTDRK) methods whose coefficients are non-constant coefficients involving $\omega$ [46, 47, 48]. An extensive survey of these methods can be found in [42, 54] and the references therein. We also note that explicit EFTDRK methods with optimal phase properties were derived in [17, 18, 14].

In this paper, we combine the idea of DIRK and EFTDRK methods to construct a new class of exponentially fitted two-derivative diagonally implicit Runge–Kutta (EFTDDIRK) methods up to order six. In contrast to the previous work, we directly formulate the general format of these methods specially for oscillatory systems (called modified two-derivative DIRK schemes) by allowing coefficients to be functions of a complex variable $\mu = i\omega h$ involving the frequency $\omega$ and the stepsize $h$. We then use a set of bi-coloured rooted trees to represent the expansion of the exact and the numerical solution, and thus derive new elementary weights. This allows us to easily derive the order conditions for high-order methods. Next, using the idea of EFTDRK approach, we obtain some preliminary results leading to new exponential fitting conditions of high-order. With these in place, we were able to construct EFTDDIRK methods of high-order using only a few stages. In particular, with $s = 2$ stages we obtain superconvergent schemes of order $p = 2s$ and $p = 2s + 1$, and with $s = 3$ stages, a method of order $p = 2s$ is derived. This is a significant improvement since previous EFTDRK methods (either explicit or fully implicit) [12, 32, 4, 13] only achieve orders $p = 2s$ for $s = 2$ stages and $p = 2s - 1$ for $s = 3$ stages.

The outline of the paper is as follows. In Section 2 we introduce the modified two-derivative diagonally implicit Runge–Kutta method (TDDIRK) for solving (1.1) and derive their order conditions (Lemma 2.1 and Theorem 2.1). In Section 3 we present a theoretical framework to establish exponential fitting conditions for these modified TDDIRK methods (Theorem 3.1). This gives rise to EFTDDIRK methods. With the classical order conditions and exponential fitting conditions in hand, we are able to derive EFTDDIRK schemes of orders up to six in Section 4. Our main results in this section
are the new schemes EFTDDIRK2s4\((c_1, c_2, \phi)\) (a family of 2-stage fourth-order methods), EFTDDIRK2s5 (a 2-stage fifth-order method), and EFTDDIRK3s6 (a 3-stage sixth-order method). The stability and phase properties of these new methods are studied in Section 5, in which the new fourth-order schemes are optimized for their accuracy. A technique for the estimation of frequency needed for the implementation of EFTDDIRK methods is discussed in Section 6. Section 7 devotes to the numerical experiments, in which the effectiveness of the new EFTDDIRK methods is demonstrated. Finally, we give some concluding remarks in Section 8.

2. Numerical method

In this section, we introduce so-called modified two-derivative diagonally implicit Runge–Kutta methods (TDDIRK) for solving (1.1) and derive their order conditions. Our idea was motivated by [14], in which the modified explicit two-derivative Runge–Kutta (TDRK) methods were introduced.

2.1. Modified two-derivative diagonally implicit Runge–Kutta methods

For the numerical solution of oscillatory problems (1.1), we define an s-stage modified TDDIRK method by the following formulation:

\[
Y_i = y_n + \xi_i(\mu)c_i h f(y_n) + h^2 \sum_{j=1}^{i} a_{ij}(\mu) g(Y_j), \quad i = 1, \ldots, s, \tag{2.1a}
\]

\[
y_{n+1} = y_n + h f(y_n) + h^2 \sum_{i=1}^{s} b_i(\mu) g(Y_i). \tag{2.1b}
\]

Here, \(h\) is the stepsize, \(g(y) = y'' = f'(y)f(y)\), and \(\mu = i\omega h\), where \(\omega > 0\) is an accurate estimate of the principal frequency of the problem. The coefficients \(\xi_i(\mu), b_i(\mu), \) and \(a_{ij}(\mu)\) are assumed to be complex differentiable on their domains. Furthermore, they are also supposed to be even functions of \(\mu\) (this will be justified later in Section 3, see Lemma 3.2).

Note that the coefficients in (2.1) can be represented in a Butcher’s type tableau with \(c = (c_1, \ldots, c_s)^T, \quad \xi(\mu) = (\xi_1(\mu), \ldots, \xi_s(\mu))^T, \quad b(\mu) = (b_1(\mu), \ldots, b_s(\mu))^T, \) and \(A(\mu) = [a_{ij}(\mu)]_{i,j=1}^{s}.\)
2.2. Local error and order conditions

To derive general order conditions for the proposed scheme (2.1), we consider \( y_{n+1} \) as the numerical solution at \( x_n + h \) obtained after one step starting from \( y(x_n) \) with the local assumption that \( y(x_n) = y_n \). Similar to the derivation of the order conditions for Runge–Kutta methods, the idea is then to compare the series expansion of \( y_{n+1} \) with that of the exact solution \( y(x_n + h) \) (in terms of the stepsize \( h \)) to study the local error

\[
LTE_n = y(x_n + h) - y_{n+1}.
\]

(2.2)

For a sufficient smooth solution \( y(x) \), the modified TDDIRK method (2.1) is said to be of order \( p \) (consistency) if the local truncation error of the solution satisfies

\[
LTE_n = O(h^{p+1}) \text{ as } h \to 0.
\]

(2.3)

For deriving schemes of high order, it turns out that the expansion of the numerical and exact solution become much more complicated. In this regard, the rooted tree theory significantly simplifies the derivation of order conditions (e.g., see [9, 25] for classical Runge-Kutta methods and see [14] for modified TDRK methods). Here, we adapt this approach to the proposed modified TDDIRK methods.

2.2.1. Expansion of the exact solution

Assume that \( f(y) \) is sufficiently differentiable (thus \( g(y) \)), one can then expand \( y(x_n + h) \) using the Taylor series about \( x_n \) to obtain

\[
y(x_n + h) = y_n + hf + \frac{h^2}{2!}f + \frac{h^3}{3!}f' + \frac{h^4}{4!}g + g''(f, f) + \ldots
\]

(2.4)

where \( f \) and \( g \) and their derivatives are the short abbreviations representing that they are evaluated at \( y_n \). Generalizing (2.4) in terms of rooted trees, one can show that

\[
y(x_n + h) = y_n + \sum_{\tau \in \mathcal{BT}} \frac{h^{\rho(\tau)}}{\rho(\tau)!} \alpha(\tau) \mathcal{F}(\tau)(y_n)
\]

(2.5)

where \( \mathcal{BT} \) is the set of bi-coloured trees

\[
\mathcal{BT} = \{ \ldots \}
\]
associated with the recursively generated elementary differentials \( F(\tau)(y_n) = \{ f, g, g'f, g'g, g''(f, f), \ldots \}, \tau \in \mathcal{B}_T \), \( \rho(\tau) \) is the order of the tree \( \tau \), \( \alpha(\tau) \) is the number of monotonic labellings of \( \tau \in \mathcal{B}_T \), as respectively defined in a recursive approach, see \([14, \text{Appendix}]\).

### 2.2.2. Expansion of the numerical solution

First, inserting the internal stages (2.1a) into (2.1b) gives

\[
y_{n+1} = y_n + hf + h^2 \sum_{i=1}^{s} b_i(\mu)g\left(y_n + \xi_i(\mu)c_i hf + h^2 \sum_{j=1}^{s} a_{ij}(\mu)g(Y_j)\right). \tag{2.6}
\]

Then, we expand the function \( g \) in (2.6) in Taylor series about \( y_n \) to obtain

\[
y_{n+1} = y_n + \frac{h}{1!} \cdot 1!' f + \frac{h^2}{2!} \cdot 2!' \cdot 1 \cdot \sum_{i=1}^{s} b_i(\mu)g + \frac{h^3}{3!} \cdot 3!' \cdot 1 \cdot \sum_{i=1}^{s} b_i(\mu)(\xi_i(\mu)c_i)g'f
+
\frac{h^4}{4!} \cdot 4!' \cdot 1 \cdot \sum_{i=1}^{s} b_i(\mu) \sum_{j=0}^{s} a_{ij}(\mu)g'g
+
\frac{h^4}{4!} \cdot 12 \cdot 1 \cdot \sum_{i=1}^{s} b_i(\mu)(\xi_i(\mu)c_i)^2 g''(f, f) + \ldots
\tag{2.7}
\]

Now using the set of bi-coloured trees \( \mathcal{B}_T \), we derive a general expansion of (2.7) as

\[
y_{n+1} = y_n + \sum_{\tau \in \mathcal{B}_T} \frac{h^{\rho(\tau)}}{\rho(\tau)!} \gamma(\tau)\alpha(\tau)\Phi(\tau)F(\tau)(y_n), \tag{2.8}
\]

where \( \gamma(\tau) \) is the density of \( \tau \) and \( \Phi(\tau) \) is the elementary weight function (depending on \( A(\mu), b(\mu), \xi(\mu) \) and \( c \)), which are recursively defined respectively as follows:

\[
\gamma(\tau) = \begin{cases} 
1, & \tau = \bullet \\
2, & \tau = \hat{\bullet} \\
\rho(\tau)(\rho(\tau) - 1)\gamma(\tau_1)\cdots\gamma(\tau_m), & \tau = [\tau_1, \ldots, \tau_m]_2,
\end{cases}
\]

and

\[
\Phi(\tau) = \begin{cases} 
\sum_{i=1}^{s} b_i(\mu), & \tau = \hat{\bullet} \\
\sum_{i=1}^{s} b_i(\mu)\Phi_i(\tau_1)\cdots\Phi_i(\tau_m) & \tau = [\tau_1, \ldots, \tau_m]_2
\end{cases}
\]
with

$$
\Phi_i(\tau) = \begin{cases} 
\xi_i(\mu)c_i, & \tau = \bullet \\
\sum_{j=1}^{s} a_{ij}(\mu), & \tau = \bullet' \\
\sum_{i=1}^{s} a_{ij}(\mu)\Phi_j(\tau_1) \cdots \Phi_m(\tau_m), & \tau = [\tau_1, \ldots, \tau_m]_2.
\end{cases}
$$

Note that the new elementary weight function $\Phi(\tau)$ defined above has much simpler form than (one can show that it is equivalent to) the one defined in [14, Appendix].

2.2.3. Local error and derivation of the order conditions

By subtracting the numerical solution (2.8) from the exact solution (2.5), the local truncation error (2.2) takes the form

$$
LTE = \sum_{\tau \in BT} \frac{h^{\rho(\tau)}}{\rho(\tau)!} (\gamma(\tau)\Phi(\tau) - 1)\alpha(\tau)F(\tau)(y_n).
$$

From this, one obtains the following result at once.

**Lemma 2.1.** Assuming that the solution of the initial value problem (1.1) is sufficiently smooth. The modified two-derivative diagonally implicit Runge-Kutta method (2.2) has order of consistency $p$ if

$$
\frac{1}{\gamma(\tau)} + \mathcal{O}(h^{p+1-\rho(\tau)}) \text{ for all } \tau \in BT \text{ with } \rho(\tau) \leq p. \quad (2.10)
$$

Using (2.10), we obtain in Table 1 the general order conditions (in vector form) for the modified TDDIRK methods (2.1) of order $p$ ($2 \leq p \leq 6$), corresponding to the bi-coloured trees, the order trees, and their elementary differentials (note that, there $e = [1, \ldots, 1]^T$ and "*" denotes the component-wise product).

On the other hand, with the assumption that the coefficients $a_{ij}(\mu)$, $b_i(\mu)$ and $\xi_i(\mu)$ of (2.1) are sufficiently differentiable and even functions of $\mu = i\omega h$, they can be expanded as

$$
a_{ij}(\mu) = a_{ij}^{(0)} - a_{ij}^{(2)} \omega^2 h^2 + a_{ij}^{(4)} \omega^4 h^4 - \ldots, \quad (2.11a)
$$

$$
b_i(\mu) = b_i^{(0)} - b_i^{(2)} \omega^2 h^2 + b_i^{(4)} \omega^4 h^4 - \ldots, \quad 1 \leq i \leq j \leq s. \quad (2.11b)
$$

$$
\xi_i(\mu) = \xi_i^{(0)} - \xi_i^{(2)} \omega^2 h^2 + \xi_i^{(4)} \omega^4 h^4 - \ldots. \quad (2.11c)
$$
Table 1: Elementary differentials and general order conditions for the modified TDDIRK methods (2.1) for all trees $\tau \in \mathcal{B}T$ with $2 \leq \rho(\tau) \leq 6$.

| Tree ($\tau$) | $\rho(\tau)$ | $\mathcal{F}(\tau)(y_n)$ | Order condition(s) | No. |
|---------------|---------------|-----------------------------|--------------------|-----|
|               | 2             | $g$                         | $b(\mu) \cdot e = \frac{1}{2} + \mathcal{O}(h^{p-1})$ | 1   |
|               | 3             | $g'f$                       | $b(\mu) \cdot (\xi(\mu)e) = \frac{1}{6} + \mathcal{O}(h^{p-2})$ | 2   |
|               | 4             | $g'f$                       | $b(\mu) \cdot (A(\mu)e) = \frac{1}{24} + \mathcal{O}(h^{p-3})$ | 3   |
|               | 4             | $g''(f,f)$                  | $b(\mu) \cdot (\xi(\mu)e)^2 = \frac{1}{12} + \mathcal{O}(h^{p-3})$ | 4   |
|               | 5             | $g'gf$                      | $b(\mu) \cdot (A(\mu)(\xi(\mu)e)) = \frac{1}{120} + \mathcal{O}(h^{p-4})$ | 5   |
|               | 5             | $g''(f,g)$                  | $b(\mu) \cdot ((\xi(\mu)e)(A(\mu)e)) = \frac{1}{360} + \mathcal{O}(h^{p-4})$ | 6   |
|               | 5             | $g'''(f,f)$                 | $b(\mu) \cdot (\xi(\mu)e)^3 = \frac{1}{360} + \mathcal{O}(h^{p-4})$ | 7   |
|               | 6             | $g'gf$                      | $b(\mu) \cdot (A^2(\mu)e) = \frac{1}{120} + \mathcal{O}(h^{p-5})$ | 8   |
|               | 6             | $g'gf'(f,f)$                | $b(\mu) \cdot (A(\mu)(\xi(\mu)e)^2) = \frac{1}{360} + \mathcal{O}(h^{p-5})$ | 9   |
|               | 6             | $g''(f,g')$                 | $b(\mu) \cdot ((\xi(\mu)e)(A(\mu)(\xi(\mu)e))) = \frac{1}{180} + \mathcal{O}(h^{p-5})$ | 10  |
|               | 6             | $g''(g,g)$                  | $b(\mu) \cdot (A(\mu)e)^2 = \frac{1}{120} + \mathcal{O}(h^{p-5})$ | 11  |
|               | 6             | $g'''(f,g')$                | $b(\mu) \cdot ((\xi(\mu)e)(A(\mu)e)) = \frac{1}{60} + \mathcal{O}(h^{p-5})$ | 12  |
|               | 6             | $g'''(f,g,f)$               | $b(\mu) \cdot (\xi(\mu)e)^4 = \frac{1}{360} + \mathcal{O}(h^{p-5})$ | 13  |
Here, we only consider $\omega \neq 0$ since if otherwise (2.1) is reduced to classical two-derivative Runge–Kutta methods. With the scalar coefficients from (2.11), we define

$$A^{(\sigma)} = \begin{bmatrix}
  a_{11}^{(\sigma)} & a_{12}^{(\sigma)} & \cdots & a_{1s_1}^{(\sigma)} \\
  a_{21}^{(\sigma)} & a_{22}^{(\sigma)} & \cdots & a_{2s_2}^{(\sigma)} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{s_1}^{(\sigma)} & a_{s_2}^{(\sigma)} & \cdots & a_{ss}^{(\sigma)}
\end{bmatrix}, \quad b^{(\sigma)} = [b_1^{(\sigma)}, b_2^{(\sigma)}, \ldots, b_s^{(\sigma)}]^T,$$

$$(2.12)$$

$$\xi^{(\sigma)} = [\xi_1^{(\sigma)}, \xi_2^{(\sigma)}, \ldots, \xi_s^{(\sigma)}]^T,$$

(here $\sigma = 0, 2, 4, \ldots$) to derive the classical order conditions for (2.1) in the Theorem 2.1 below.

**Theorem 2.1.** (Classical order conditions) Under the conventional simplifying assumptions that

$$\xi^{(0)} = e, \quad A^{(0)} e = \frac{c^2}{2}, \quad (2.13)$$

the scheme (2.1) is of order $p$ consistency (for $2 \leq p \leq 6$), if the following classical order conditions are fulfilled:

- **Order 2 requires**
  $$b^{(0)} \cdot e = \frac{1}{2}, \quad (2.14)$$

- **Order 3 requires, in addition**
  $$b^{(0)} \cdot c = \frac{1}{6}, \quad (2.15)$$

- **Order 4 requires, in addition**
  $$b^{(0)} \cdot c^2 = \frac{1}{12}, \quad (2.16a)$$
  $$b^{(2)} \cdot e = 0. \quad (2.16b)$$
• Order 5 requires, in addition

\[ b^{(0)} \cdot (A^{(0)} c) = \frac{1}{120}, \]  

(2.17a)

\[ b^{(0)} \cdot c^3 = \frac{1}{20}, \]  

(2.17b)

\[ b^{(0)} \cdot (\xi^{(2)} \ast c) + b^{(2)} \cdot c = 0. \]  

(2.17c)

• Order 6 requires, in addition

\[ b^{(0)} \cdot (A^{(0)} c^2) = \frac{1}{360}, \]  

(2.18a)

\[ b^{(0)} \cdot (c \ast (A^{(0)} c)) = \frac{1}{180}. \]  

(2.18b)

\[ b^{(0)} \cdot c^4 = \frac{1}{30}, \]  

(2.18c)

\[ b^{(4)} \cdot e = 0, \]  

(2.18d)

\[ 2b^{(0)} \cdot A^{(2)} e + b^{(2)} \cdot c^2 = 0, \]  

(2.18e)

\[ 2b^{(0)} \cdot (\xi^{(2)} \ast c^2) + b^{(2)} \cdot c^2 = 0. \]  

(2.18f)

Proof. The main idea is to insert (2.11) into conditions 1–13 of Table I to derive the classical order conditions (2.14)–(2.18). We now illustrate this procedure for the case \( p = 6 \). First, consider the tree of order two \( \tau = \hat{1} \).

Inserting \( (2.11b) \) into condition 1 of Table I yields

\[ (b^{(0)} \cdot e) - (b^{(2)} \cdot e) \omega^2 h^2 + (b^{(4)} \cdot e) \omega^4 h^4 + \mathcal{O}(h^6) = \frac{1}{2} + \mathcal{O}(h^5). \]  

(2.19)

Taking the limit of both sides of (2.19) as \( h \) approaches zero results in order condition (2.14). Employing (2.14) and dividing both sides of (2.19) by \( h^2 \) gives

\[ - (b^{(2)} \cdot e) \omega^2 + (b^{(4)} \cdot e) \omega^4 h^2 + \mathcal{O}(h^4) = \mathcal{O}(h^3). \]  

(2.20)
Again, taking the limit of both sides as $h$ approaches zero ($\omega \neq 0$) implies order condition (2.16b). Dividing both sides of (2.20) by $h^2$ and keeping in mind the use of (2.16b) gives

$$ (b^{(4)} \cdot e)\omega^4 + \mathcal{O}(h^2) = \mathcal{O}(h), $$

which shows (2.18e) when taking the limit of both sides as $h \to 0$.

Next, consider $\tau = 0$. Inserting (2.11b) and (2.11c) into condition 2 of Table 1 yields

$$ (b^{(0)} \cdot c) - (b^{(0)} \cdot (\xi^{(2)}*c))\omega^2h^2 - (b^{(2)} \cdot c)\omega^2h^2 + \mathcal{O}(h^4) = \frac{1}{6} + \mathcal{O}(h^4). $$

(2.22)

From (2.22), as $h \to 0$, one immediately obtains order condition (2.15). With this, dividing (2.22) by $h^2$, we obtain

$$ - (b^{(0)} \cdot (\xi^{(2)}*c))\omega^2 - (b^{(2)} \cdot c)\omega^2 + \mathcal{O}(h^2) = \mathcal{O}(h^2). $$

(2.23)

Therefore, as $h \to 0$, (2.17c) is confirmed.

Similarly, consider $\tau = 1$. Inserting (2.11a) and (2.11b) into condition 3 of Table 1 gives

$$ b^{(0)} \cdot A^{(0)}e - (b^{(0)} \cdot A^{(2)}e + b^{(2)} \cdot A^{(0)}e)\omega^2h^2 + \mathcal{O}(h^4) = \frac{1}{24} + \mathcal{O}(h^3). $$

(2.24)

Using (2.13), one obtains (2.16a) as $h \to 0$. With (2.16a), dividing both sides by $h^2$, we obtain

$$ - (2b^{(0)} \cdot A^{(2)}e + b^{(2)} \cdot c^2)\omega^2 + \mathcal{O}(h^2) = \mathcal{O}(h). $$

(2.25)

Therefore, as $h \to 0$, we obtain (2.18e).

Furthermore, consider $\tau = 2$. Inserting (2.11c) and (2.11b) into condition 4 of Table 1 and using the first assumption in (2.13) yields

$$ b^{(0)} \cdot c^2 - (2b^{(0)} \cdot (\xi^{(2)}*c^2) + b^{(2)} \cdot c^2)\omega^2h^2 + \mathcal{O}(h^4) = \frac{1}{12} + \mathcal{O}(h^3). $$

(2.26)

Using (2.16a) and dividing both sides by $h^2$, we obtain

$$ - (2b^{(0)} \cdot (\xi^{(2)}*c^2) + b^{(2)} \cdot c^2)\omega^2 + \mathcal{O}(h^2) = \mathcal{O}(h), $$

(2.27)

which shows (2.18b) as $h \to 0$.

Continuing in this manner for other trees $\tau$ in Table 1, the remaining classical order conditions in (2.14)-(2.18) can be obtained.
3. Exponential fitting conditions

As our focus is on the IVP problem (1.1) with oscillatory solutions, it is desirable to require that the proposed scheme can integrate exactly the system whose solutions involve a linear combination of reference sets of the form \( \{ p_k(x)e^{\lambda_k x} \} \), where \( p_k(x) \) are polynomials in \( x \) and \( \lambda_k \) can be real or complex numbers (note that in the case \( \lambda_k = \pm i\omega \), such a reference set becomes \( \{ p_k(x)e^{\pm i\omega x} = p_k(x)(\cos(\omega x) \pm i\sin(\omega x)) \} \). This enforces additional requirements on the coefficients of the two-derivative Runge–Kutta methods, which are referred to the so-called exponential fitting conditions, see [30]. Therefore, along with the required order conditions given in Table 1, in this section we will derive such conditions for (2.1).

Following [30] (see also [42] and references therein), in which the explicit exponential-fitted Runge–Kutta/Runge-Kutta-Nyström methods were presented, the idea is to determine fitting conditions so that the local truncation errors of the internal stages \( Y_i \) and the final stage \( y_{n+1} \) of (2.1) vanish on a certain reference set. For this, we introduce the following linear operators

\[
L_i[h, A, c, \xi]y(x) = y(x + c_i h) - y(x) - \xi_i(\mu)c_i y'(x) - h^2 \sum_{j=1}^{i} a_{ij}(\mu)y''(x + c_j h),
\]

\[
L[h, b, c]y(x) = y(x + h) - y(x) - hy'(x) - h^2 \sum_{i=1}^{s} b_i(\mu)y''(x + c_i h),
\]

which are associated with the internal stages and the final stage, respectively \((i = 1, \ldots, s)\).

**Definition 3.1.** The scheme (2.1) is said to be exponentially fitted TDDIRK (EFTDDIRK) method of degree \((K, L)\) if

\[
L[h, b, c]y(x) \equiv 0 \quad \text{and} \quad L_i[h, A, c, \xi]y(x) \equiv 0, \quad i = 1, \ldots, s \quad (3.2)
\]

for all \( y(x) \) that belong to the subspace

\[
\mathcal{F}_{K,L} = \text{span}\{ x^k e^{\lambda_l x}, \ \lambda_l \in \mathbb{R} \text{ or } \mathbb{C}, \ k = 0, \ldots, K, \ l = 1, \ldots, L \}. \quad (3.3)
\]

On \( \mathcal{F}_{K,L} \), we prove the following important properties of the operators \( L_i \) and \( L \) defined in (3.1).
Lemma 3.1. For all \( y_K(x) = x^Ke^x \in \mathcal{F}_{K,L} \), we have

\[
\mathcal{L}_i[h, A, c, \xi]y_K(x) = \sum_{m=0}^{K} \binom{K}{m} y_m(x) \mathcal{L}_i[h, A, c, \xi]y_{K-m}(0), \quad (3.4a)
\]

\[
\mathcal{L}[h, b, c]y_K(x) = \sum_{m=0}^{K} \binom{K}{m} y_m(x) \mathcal{L}[h, b, c]y_{K-m}(0). \quad (3.4b)
\]

Proof. With \( y_K(x) = x^Ke^x \), one can verify that

\[
y_K(x + c_i h) = (x + c_i h)^Ke^{x+c_i h} = \sum_{m=0}^{K} \binom{K}{m} y_m(x)y_{K-m}(c_i h), \quad (3.5a)
\]

\[
y''_K(x) = K y'_{K-1}(x) + \lambda_i y_K(x), \quad (3.5b)
\]

\[
y''_K(x) = K(K-1)y_{K-2}(x) + 2K\lambda_i y_{K-1}(x) + \lambda_i^2 y_K(x). \quad (3.5c)
\]

Inserting (3.5a) and (3.5b) into (3.1a) gives

\[
\mathcal{L}_i[h, A, c, \xi]y_K(x) = \sum_{m=0}^{K} \binom{K}{m} y_m(x)y_{K-m}(c_i h) - y_K(x)
\]

\[- \gamma_i(\mu)c_i h[K y_{K-1}(x) + \lambda_i y_K(x)] - h^2 \sum_{j=1}^{i} a_{ij}(\mu)y''_K(x + c_j h). \quad (3.6)
\]

Using (3.5c) and (3.5a) (with \( c_j \) in place of \( c_i \)), we obtain

\[
y''_K(x + c_j h) = K(K-1)y_{K-2}(x + c_j h) + 2K\lambda_i y_{K-1}(x + c_j h) + \lambda_i^2 y_K(x + c_j h)
\]

\[
= K(K-1) \sum_{m=0}^{K-2} \binom{K-2}{m} y_m(x)y_{K-2-m}(c_j h)
\]

\[+ 2K\lambda_i \sum_{m=0}^{K-1} \binom{K-1}{m} y_m(x)y_{K-1-m}(c_j h)
\]

\[+ \lambda_i^2 \sum_{m=0}^{K} \binom{K}{m} y_m(x)y_{K-m}(c_j h). \quad (3.7)
\]

Next, we insert (3.7) into (3.6) and factor out the terms \( y_K(x), \binom{K}{K-1} y_{K-1}(x) = Ky_{K-1}(x) \), and \( \sum_{m=0}^{K-2} \binom{K}{m} y_m(x) \) from the obtained result. It is then not dif-
ficult to show that (3.6) becomes
\[
\mathcal{L}_i[h, A, c, \xi]y_K(x) = y_K(x)\mathcal{L}_i[h, A, c, \xi]y_0(0) + Ky_{K-1}(x)\mathcal{L}_i[h, A, c, \xi]y_1(0) + \sum_{m=0}^{K-2} \binom{K}{m} y_m(x)\mathcal{L}_i[h, A, c, \xi]y_{K-m}(0)
\]
which proves (3.4a).
Note that using (3.5a) (with \(c_i = 1\)) and (3.7) (with \(c_i\) in place of \(c_j\)), the proof of (3.4b) can be carried out in the same way. We omit the details. \(\square\)

With the result of Lemma 3.1 in hand, we are ready to state the fitting conditions for the proposed method (2.1).

**Theorem 3.1.** (Fitting conditions) **Under the following conditions**
\[
\mathcal{L}_i[h, A, c, \xi]y_m(0) = 0, \quad \mathcal{L}[h, b, c]y_m(0) = 0, \tag{3.8}
\]
for all \(y_m(x) = x^m e^{\lambda_i x} \in \mathcal{F}_{K,L}\) with \(m = 0, 1, 2, \ldots, K\) and \(l = 0, 1, 2, \ldots, L\), the scheme (2.1) is an EFTDDIRK method of degree \((K, L)\). In particular, we have:

- **Degree** \((0, L)\) requires the following fitting conditions
  \[
  (\lambda_i h)^2 \sum_{j=1}^{i} a_{ij}(\mu)e^{c_i \lambda_i h} + \xi_i(\mu)c_i \lambda_i h = e^{c_i \lambda_i h} - 1, \tag{3.9a}
  \]
  \[
  (\lambda_i h)^2 \sum_{i=1}^{s} b_i(\mu)e^{c_i \lambda_i h} = e^{\lambda_i h} - 1 - \lambda_i h. \tag{3.9b}
  \]

- **Degree** \((1, L)\) requires, in addition to (3.9), the following conditions
  \[
  \sum_{j=1}^{i} a_{ij}(\mu)[2\lambda_i h + c_j(\lambda_i h)^2]e^{c_j \lambda_i h} + \xi_i(\mu)c_i = c_i e^{c_i \lambda_i h}, \tag{3.10a}
  \]
  \[
  \sum_{i=1}^{s} b_i(\mu)[2\lambda_i h + c_i(\lambda_i h)^2]e^{c_i \lambda_i h} = e^{\lambda_i h} - 1. \tag{3.10b}
  \]
• Degree \((K \geq 2, L)\) requires, in addition to \((3.9)\) and \((3.10)\)

\[
\sum_{j=1}^{i} a_{ij}(\mu) \left[ K(K-1)c_j^{K-2} + 2K c_j^{K-1} \lambda_i h + c_j^K(\lambda_i h)^2 \right] e^{c_j \lambda_i h} = c_i^K e^{c_i \lambda_i h},
\]

\((3.11a)\)

\[
\sum_{i=1}^{s} b_i(\mu) \left[ K(K-1)c_i^{K-2} + 2K c_i^{K-1} \lambda_i h + c_i^K(\lambda_i h)^2 \right] e^{c_i \lambda_i h} = e^{\lambda_i h}.
\]

\((3.11b)\)

**Proof.** The first part of Theorem 3.1 follows directly from Lemma 3.1. More specifically, \((3.8)\) implies at once \((3.2)\) for all \(y(x) \in \mathcal{F}_{K,L}\). Next, we work out \((3.8)\), i.e.,

\[
\mathcal{L}_i[h, A, c, \xi] y_m(0) = y_m(c_i h) - y_m(0) - \xi_i(\mu)c_i h y'_m(0) - h^2 \sum_{j=1}^{i} a_{ij}(\mu) y''_m(c_j h) = 0,
\]

\((3.12a)\)

\[
\mathcal{L}[h, b, c] y_m(0) = y_m(h) - y_m(0) - h y'_m(0) - h^2 \sum_{i=1}^{s} b_i(\mu) y''_m(c_i h) = 0.
\]

\((3.12b)\)

For \(K = 0\), we have \(m = 0\) and thus consider \(y_0(x) = e^{\lambda x}\). A simple calculation shows that \(y_0(c_i h) = e^{c_i \lambda_i h}\), \(y_0(0) = 1\), \(y'_0(0) = \lambda_i\), and \(y''_0(c_j h) = \lambda_i^2 e^{c_j \lambda_i h}\). Inserting these into \((3.12)\) shows \((3.9)\) at once. For \(K = 1\), we have \(m = 0, 1, \) and thus consider, in addition to \(y_0(x)\), \(y_1(x) = xe^{\lambda x}\). Again, one can easily verify \((3.10)\) by plugging \(y_1(c_i h) = c_i h e^{c_i \lambda_i h}\), \(y'_1(0) = 0\), \(y''_1(0) = 1\), and \(y''_1(c_j h) = (2\lambda_i + \lambda_j^2 c_j h)e^{c_j \lambda_i h}\) into \((3.12)\). Similarly, \((3.11)\) is confirmed for \(K \geq 2\) (i.e., \(m = 0, 1, 2, \ldots, K\)) by considering \(y_K(x) = x^K e^{\lambda x}\).

As a direct consequence of Theorem 3.1, we obtain the following result for EFTDDIRK methods of degree \((0, L)\).

**Corollary 3.1.** An EFTDDIRK method of degree \((0, L)\) with the coefficients \(b_i(\mu)\) expanded as \((2.11b)\) has order of consistency at least three.

**Proof.** Based on Theorem 3.1, we have that an EFTDDIRK method of degree \((0, L)\) satisfies the fitting condition \((3.9)\). Employing the Taylor expansions
$e^{c_i \lambda_l h} = 1 + c_i \lambda_l h + \mathcal{O}(h^2)$ and $e^{\lambda_l h} = 1 + \lambda_l h + \frac{1}{2}(\lambda_l h)^2 + \frac{1}{6}(\lambda_l h)^3 + \mathcal{O}(h^4)$, one can express (3.9b) as

$$\sum_{i=1}^{s} b_i(\mu) + \left( \sum_{i=1}^{s} b_i(\mu) c_i \right) \lambda_l h + \mathcal{O}(h^2) = \frac{1}{2} + \frac{1}{6} \lambda_l h + \mathcal{O}(h^2).$$

(3.13)

Inserting $b_i(\mu) = b_i^{(0)} + \mathcal{O}(\omega^2 h^2)$ (from (2.11)) into (3.13) and taking the limit of both sides as $h$ approaches 0 shows that

$$\sum_{i=1}^{s} b_i^{(0)} = \frac{1}{2}.$$

(3.14)

With this, (3.13) can be simplified as

$$\left( \sum_{i=1}^{s} b_i^{(0)} c_i - \frac{1}{6} \lambda_l h \right) + \mathcal{O}(h) = \mathcal{O}(h),$$

(3.15)

which implies

$$\sum_{i=1}^{s} b_i^{(0)} c_i = \frac{1}{6}$$

(3.16)

when $h$ approaches 0. Clearly, (3.14) and (3.16) are the order conditions for EFTDDIRK methods of order 3.

We note that this result is similar to a result for the trigonometrically fitted two-derivative Runge–Kutta methods [18] which holds for $s \geq 2$.

Next, in order to allow a direct treatment of oscillatory solutions, we now consider the case $\lambda_l = \pm i \omega$, $l = 0, 1, \ldots, L$. Since $\mu = i \omega h$, we have $\lambda_l h = \pm l \mu$. Therefore, the fitting condition (3.9) of EFTDDIRK methods of degree $(0, L)$ becomes

$$(l \mu)^2 \sum_{j=1}^{i} a_{ij}(\mu) e^{\pm c_j l \mu} \pm \xi_i(\mu)c_i l \mu = e^{\pm c_l l \mu} - 1,$$

(3.17a)

$$(l \mu)^2 \sum_{i=1}^{s} b_i(\mu) e^{\pm c_l l \mu} = e^{\pm l \mu} - 1 \mp l \mu.$$

(3.17b)

When $l = 1$, we have the following observation.
Corollary 3.2. The fitting conditions in (3.17) for an EFTDDIRK method of degree (0, 1) whose coefficients expanded as in (2.11) imply the following

\begin{align}
\xi_i^{(0)} &= 1, \quad \sum_{j=1}^{i} a_{ij}^{(0)} = \frac{c_i^2}{2}, \quad (3.18a) \\
\sum_{j=1}^{i} a_{ij}^{(0)} c_j + \xi_i^{(2)} c_i &= \frac{1}{3!} c_i^3, \quad (3.18b) \\
\frac{1}{2!} \sum_{j=1}^{i} a_{ij}^{(0)} c_j^2 + \sum_{j=1}^{i} a_{ij}^{(2)} &= \frac{1}{4!} c_i^4, \quad (3.18c) \\
\sum_{i=1}^{s} b_i^{(0)} &= \frac{1}{2!}, \quad \sum_{i=1}^{s} b_i^{(0)} c_i = \frac{1}{3!}, \quad (3.18d) \\
\frac{1}{2!} \sum_{i=1}^{s} b_i^{(0)} c_i^2 + \sum_{i=1}^{s} b_i^{(2)} &= \frac{1}{4!}, \quad (3.18e) \\
\frac{1}{3!} \sum_{i=1}^{s} b_i^{(0)} c_i^3 + \sum_{i=1}^{s} b_i^{(2)} c_i &= \frac{1}{5!}, \quad (3.18f) \\
\frac{1}{4!} \sum_{i=1}^{s} b_i^{(0)} c_i^4 + \frac{1}{2!} \sum_{i=1}^{s} b_i^{(2)} c_i^2 + \sum_{i=1}^{s} b_i^{(4)} &= \frac{1}{6!}. \quad (3.18g)
\end{align}

Proof. The proof is straightforward by inserting (2.11) and the Taylor series expansions of $e^{\xi \mu}$, $e^{c_i \mu}$, $e^{\mu}$ into (3.17) with $l = 1$ and comparing term by term on both sides of each condition. We omit the details. Here, we note that (3.18d) is already obtained in Corollary 3.1 for the more general case, and (3.18a) justifies the simplifying assumption needed in Theorem 2.1.

Finally, we justify the assumption on the coefficients $a_{ij}(\mu), b_i(\mu)$, and $\xi_i(\mu)$ stated in the Subsection 2.1.

Lemma 3.2. If the fitting conditions in (3.17) are held for all $\mu$, the coefficients $a_{ij}(\mu), b_i(\mu)$, and $\xi_i(\mu)$ must be even functions.

Proof. Adding the two equations in (3.17a) gives

\[(l \mu)^2 \sum_{j=1}^{i} a_{ij}(\mu) (e^{\xi_j l \mu} + e^{-\xi_j l \mu}) = e^{\xi_j l \mu} + e^{-\xi_j l \mu} - 2. \quad (3.19)\]
Interchanging $\mu \to -\mu$ and subtracting the resulted equation from (3.19) leads to

$$
\sum_{j=1}^{i} [a_{ij}(\mu) - a_{ij}(-\mu)](e^{c_{ij}l\mu} + e^{-c_{ij}l\mu}) = 0. 
$$

(3.20)

This shows $a_{ij}(\mu) = a_{ij}(-\mu)$ due to the fact that the functions $\{e^{c_{ij}l\mu} + e^{-c_{ij}l\mu}\}_{j=1}^{i}$ are linearly independent. Similarly, using (3.17b) one can show that $b_{i}(\mu) = b_{i}(-\mu)$. Next, interchanging $\mu \to -\mu$ for the first equation in (3.17a) and subtracting from the other, we have

$$
(l\mu)^{2} \sum_{j=1}^{i} [a_{ij}(\mu) - a_{ij}(-\mu)]e^{-c_{ij}l\mu} - [\xi_{i}(\mu) - \xi_{i}(-\mu)]c_{i} \mu = 0. 
$$

(3.21)

Since $a_{ij}(\mu) = a_{ij}(-\mu)$, one derives $\xi_{i}(\mu) = \xi_{i}(-\mu)$. □

4. Construction of EFTDDIRK methods

In this section, using the results presented in Theorem 2.1 and Theorem 3.1, we construct EFTDDIRK methods based on the reference set (3.3) with $K = 0$ and $L = 1$, i.e., methods of degree $(0,1)$. This is the case in which these methods can integrate exactly differential equations with oscillating solutions involving $e^{\pm \omega x} = \cos(\omega x) \pm i \sin(\omega x)$. Since EFTDDIRK methods are at least of order 3, i.e., the order conditions (2.14)–(2.15) are automatically satisfied (as shown in Corollary 3.1), we will derive methods of orders 4, 5, and 6 by using the fitting conditions in (3.17) and the remaining required order conditions (2.16)–(2.18).

Clearly, with $s = 1$, it is not possible to construct fourth-order EFTDDIRK methods. Therefore, we start off our construction with $s = 2$. For later use, we define

$$
E_{\mu}^{+}(\zeta) = e^{\zeta \mu} + e^{-\zeta \mu}, \quad E_{\mu}^{-}(\zeta) = e^{\zeta \mu} - e^{-\zeta \mu}. 
$$

(4.1)
4.1. Two-stage fourth-order methods

The fitting conditions in (3.17) and the required order conditions (2.16) for this case ($s = 2$) now read as

\begin{align*}
\mu^2 a_{11}(\mu)e^{\pm c_1 \mu} \pm \xi_1(\mu)c_1 \mu &= e^{\pm c_1 \mu} - 1, \\
\mu^2 a_{21}(\mu)e^{\pm c_1 \mu} + \mu^2 a_{22}(\mu)e^{\pm c_2 \mu} \pm \xi_2(\mu)c_2 \mu &= e^{\pm c_2 \mu} - 1, \\
\mu^2 b_1(\mu)e^{\pm c_1 \mu} + \mu^2 b_2(\mu)e^{\pm c_2 \mu} &= e^{\pm \mu} - 1 \mp \mu, \\
b_1^{(0)}c_1^2 + b_2^{(0)}c_2^2 &= \frac{1}{12}, \\
b_1^{(2)} + b_2^{(2)} &= 0,
\end{align*}

respectively. While solving (4.2a) gives $a_{11}(\mu)$ and $\xi_1(\mu)$ at once, solving (4.2c) gives $b_1(\mu)$ and $b_2(\mu)$. Since (4.2d) includes two equations with three unknown coefficients, one can take one of them as a free parameter. For instance, we take $a_{21}(\mu)$ as a free parameter and set it as $a_{21}(\mu) = \phi$. Putting altogether, we display the solution to (4.2) as follows:

\begin{align*}
a_{11}(\mu) &= \frac{1}{\mu}(1 - \frac{2}{\mu c_1^{(c_1)}(c_1)}), \quad a_{21}(\mu) = \phi, \quad a_{22}(\mu) = \frac{E_{\mu}^+(c_2)-(2+\phi^2E_{\mu}^+(c_1))}{\mu^2E_{\mu}^+(c_2)}, \\
\xi_1(\mu) &= \frac{E_{\mu}^-(c_1)}{c_1\mu E_{\mu}^+(c_1)}, \quad \xi_2(\mu) = \frac{E_{\mu}^-(c_2)-\phi^2E_{\mu}^-(c_1-c_2)}{E_{\mu}^+(c_1-c_2)}, \\
b_1(\mu) &= \frac{E_{\mu}^-(c_2)+E_{\mu}^-(1-c_2)-\mu E_{\mu}^+(c_1-c_2)}{\mu^2E_{\mu}^-(c_1-c_2)}, \quad b_2(\mu) = \frac{\mu E_{\mu}^+(c_1)-E_{\mu}^-(c_1)-E_{\mu}^-(1-c_1)}{\mu^2E_{\mu}^-(c_1-c_2)}.
\end{align*}

Next, we solve for the two order conditions (4.2d)–(4.2e). Due to (3.18c) (see Corollary 3.2 for $s = 2$), we see that one only needs to satisfy one of them (as the other one will be then automatically satisfied). For instance, we solve (4.2d) by expanding $b_1(\mu)$ and $b_2(\mu)$ in (4.3) in Taylor series as

\begin{align*}
b_1(\mu) &= \frac{1-3c_2}{6(c_1-c_2)} + \frac{10(c_1-2c_2)(c_1-3c_1c_2)-20c_2^2+15c_2^2-3}{360(c_1-c_2)} \omega^2 h^2 + O(h^4) \quad (4.4a) \\
b_2(\mu) &= \frac{3c_1-1}{6(c_1-c_2)} + \frac{10(c_2-2c_1)(3c_1c_2-c_2)+20c_1^2-15c_1+3}{360(c_1-c_2)} \omega^2 h^2 + O(h^4) \quad (4.4b)
\end{align*}

(to get $b_1^{(0)}$, $b_2^{(0)}$), and thus obtain a constraint for $c_1$ and $c_2$:

\[
\frac{1-3c_2}{6(c_1-c_2)} + \frac{3c_1-1}{6(c_1-c_2)} = \frac{1}{12} \iff 2(c_1 + c_2 - 3c_1c_2) - 1 = 0 \quad (4.5)
\]
for all $c_1 \neq c_2$. Overall, this results in a family of fourth-order 2-stage methods which will be called $\text{EFTDDIRK2s4}(c_1, c_2, \phi)$. For example, solving (4.5) with a choice of $c_1 = 1/4$ leads to $c_2 = 1$, denoted $\text{EFTDDIRK2s4}(\frac{1}{4}, 1, \phi)$. Another solution is to choose $c_1 = 0$, resulting in $c_2 = 1/2$, and $a_{11}(\mu) = 0$ (the first stage is explicit), denoted $\text{EFTDDIRK2s4}(0, \frac{1}{2}, \phi)$. The parameter $\phi$ will be determined by the optimizing the phase property of the methods. This will be discussed in the next section.

4.2. Two–stage fifth-order methods

In this subsection, we consider whether using $s = 2$ is possible to derive a fifth-order method. For this, in addition to (4.2), the conditions in (2.17) are required. Supposed that (2.17b) is satisfied, one derives $b^{(2)} \cdot c = 0$ due to (3.18c) in Corollary 3.2. With this, (2.17c) is now simplified to

\[ b^{(0)} \cdot (\xi^{(2)} \ast c) = 0 \iff b_1^{(0)} \xi_1^{(2)} c_1 + b_2^{(0)} \xi_2^{(2)} c_2 = 0. \]  

(4.6)

Next, using (3.18b) which can be written as $A^{(0)} c + \xi^{(2)} \ast c = \frac{1}{3!} c^3$, we have

\[ b^{(0)} \cdot (A^{(0)} c) = \frac{1}{3!} b^{(0)} \cdot c^3 - b^{(0)} \cdot (\xi^{(2)} \ast c) = \frac{1}{3!} - 0 = \frac{1}{20}. \]

This shows that (2.17a) is then automatically satisfied. Therefore, to fulfill (2.17), we eventually need to solve (2.17b) and (4.6) only.

Expanding $\xi_i(\mu)$ (see (4.3)) in Taylor series

\[ \xi_1(\mu) = 1 + \frac{c^2}{3!} \omega^2 h^2 + O(h^4), \quad \xi_2(\mu) = 1 - \left( \phi - \frac{\phi c_1}{c_2} - \frac{c_2^2}{3!} \right) \omega^2 h^2 + O(h^4) \]  

(4.7)

to get $\xi_1^{(2)}$, $\xi_2^{(2)}$ and employing (4.4), the two conditions (2.17b) and (4.6) become

\[ \frac{1 - 3c_2}{6(c_1 - c_2)} c_1^3 + \frac{3c_1 - 1}{6(c_1 - c_2)} c_2^3 = \frac{1}{20} \iff c_1^2 + c_2^2 + c_1 c_2 - 3c_1 c_2 (c_1 + c_2) = \frac{3}{10} \]  

(4.8)

(for all $c_1 \neq c_2$) and $\frac{1 - 3c_2}{6(c_1 - c_2)} (\frac{c_1^3}{3}) + \frac{3c_1 - 1}{6(c_1 - c_2)} (\phi - \frac{\phi c_1}{c_2} - \frac{c_2^2}{3!}) c_2 = 0$, respectively. Note that, with $c_1 \neq c_2$, the later equation can be simplified as

\[ c_1^2 + c_2^2 - 3c_1 c_2 (c_1 + c_2) + c_1 c_2 + 3\phi(3c_1 - 1) = 0 \iff \phi = \frac{1}{10(1 - 3c_1)} \]  

(4.9)

by employing (4.8). Clearly, $c_1$ and $c_2$ can be easily solved from the system of two algebraic equations (4.5) (to fulfill (4.2)) and (4.8) (indeed, given the form of this system, $c_1$ and $c_2$ are the two roots of the quadratic equation
Now that we have the solution, we obtain the Taylor's expansion of the coefficients given in \((4.3)\) for this case \((s = 3)\) now gives

\[
\begin{align*}
c_1 &= \frac{1}{10}(4 - \sqrt{6}), \quad c_2 = \frac{1}{10}(4 + \sqrt{6}), \quad \phi = \frac{1}{50}(2 + 3\sqrt{6}). \quad (4.10)
\end{align*}
\]

This results in a 2-stage fifth-order method with the coefficients given in \((4.3)\) and \((4.10)\) which will be called EFTDDIRK2s5.

### 4.3. Three-stage sixth-order method

For a 3-stage method, the exponential fitting conditions using \((3.17)\) now gives

\[
\begin{align*}
\mu^2 a_{11}(\mu)e^{\pm c_1 \mu} \pm \xi_1(\mu)c_1 \mu &= e^{\pm c_1 \mu} - 1, \quad (4.11a) \\
\mu^2 a_{21}(\mu)e^{\pm c_1 \mu} + \mu^2 a_{22}(\mu)e^{\pm c_2 \mu} \pm \xi_2(\mu)c_2 \mu &= e^{\pm c_2 \mu} - 1, \quad (4.11b) \\
\mu^2 a_{31}(\mu)e^{\pm c_1 \mu} + \mu^2 a_{32}(\mu)e^{\pm c_2 \mu} + \mu^2 a_{33}(\mu)e^{\pm c_3 \mu} \pm \xi_3(\mu)c_3 \mu &= e^{\pm c_3 \mu} - 1, \quad (4.11c) \\
\mu^2 b_1(\mu)e^{\pm c_1 \mu} + \mu^2 b_2(\mu)e^{\pm c_2 \mu} + \mu^2 b_3(\mu)e^{\pm c_3 \mu} &= e^{\pm \mu} - 1 + \mu. \quad (4.11d)
\end{align*}
\]

In addition to \((4.11)\), we require the coefficients to satisfy the classical order conditions \((2.14)\)–\((2.18)\). As in the two-stage method, one can similarly solve \((4.11a)\) for \(a_{11}(\mu)\) and \(\xi_1(\mu)\). Next, we solve parameters \((4.11b)\) for \(\xi_2(\mu)\) and \(a_{22}(\mu)\), while we make \(a_{21}(\mu) = \chi\) a free parameter. Furthermore, we solve \((4.11c)\) for \(\xi_3(\mu)\) and \(a_{33}(\mu)\), while setting \(a_{31}(\mu) = \beta\) and \(a_{32}(\mu) = \delta\) as free parameters. Lastly, setting \(b_2(\mu) = \eta\) as a free parameter in \((4.11d)\), we solve for \(b_1(\mu)\) and \(b_3(\mu)\). The solution to \((4.11)\) therefore yields the following:

\[
\begin{align*}
\xi_1(\mu) &= \frac{E_{\mu}^+(c_1) - \mu^2 (3E_{\mu}^+(c_1) + \delta E_{\mu}^+(c_2)) - 2}{c_1 \mu E_{\mu}^+(c_3)}, \\
\xi_2(\mu) &= \frac{E_{\mu}^-(c_3) - \mu \mu^2 E_{\mu}^-(c_1 - c_2)}{E_{\mu}^-(c_3)}, \quad \xi_3(\mu) = \frac{E_{\mu}^-(c_3) - \mu^2 (3E_{\mu}^-(c_1 - c_3) + \delta E_{\mu}^- (c_2 - c_3))}{c_3 \mu E_{\mu}^-(c_3)}, \\
b_1(\mu) &= \frac{E_{\mu}^- (c_1) - E_{\mu}^-(c_3) - \mu E_{\mu}^+(c_1) - \eta \mu^2 E_{\mu}^- (c_1 - c_3)}{\mu^2 E_{\mu}^-(c_1 - c_3)}, \\
b_3(\mu) &= \frac{\mu E_{\mu}^+(c_1) - E_{\mu}^+(c_1) - \mu E_{\mu}^+(c_1) - \eta \mu^2 E_{\mu}^- (c_1 - c_2)}{\mu^2 E_{\mu}^-(c_1 - c_3)}.
\end{align*}
\]
conditions (2.14)–(2.18). With the help of Corollary 3.2, the classical order conditions (2.16a), (2.17b), (2.17c), (2.18a), (2.18b), and (2.18c) are sufficient to attain order six. These set of conditions, yield a system of cumbersome algebraic equations, which are omitted here. The free parameters satisfy the sixth-order conditions with

\[ c_1 = 0, \quad c_2 = \frac{1}{10}(5 - \sqrt{5}), \quad c_3 = \frac{1}{10}(5 + \sqrt{5}), \quad \chi = \frac{1}{30}(3 - \sqrt{5}), \]

\[ \beta = \frac{1}{60}(1 + \sqrt{5}), \quad \delta = \frac{1}{60}(5 + 3\sqrt{5}), \quad \eta = \frac{1}{24}(5 + \sqrt{5}). \]

This method is denoted as EFTDDIRK3s6.

**Remark 4.1.** For small values of \( \mu \), the coefficients are subject to heavy cancellations and then in practical computation, it is preferable to use the truncated Taysors series. We note that as \( \mu \to 0 \) the new EFTDDIRK reduce to the underlying TDDIRK with constant coefficients belonging to the class of methods proposed in [4]. However, the underlying methods (\( \mu \to 0 \)) here are different from the ones presented in [4].

5. Phase and stability properties

This section is concerned with the stability and phase-lag analysis of the EFTDDIRK methods derived in Section 4. Following [18, 50] for oscillatory systems, we apply the method (2.1) to the test equation

\[ y' = i\Lambda y, \quad \Lambda > 0. \]  

(5.1)

This results in the following difference equation

\[ y_{n+1} = R(i\theta, \omega h)y_n, \quad \theta = \Lambda h, \quad i^2 = -1, \]  

(5.2)

where \( R(i\theta, \omega h) \) is the stability function given as

\[ R(i\theta, \omega h) = (1 - \theta^2b(\mu)^T(I_s + \theta^2A(\mu))^{-1}e) + i(\theta(1 - \theta^2)b(\mu)^T(I_s + \theta^2A(\mu))^{-1}(\xi \ast c)) \]  

(5.3)

(here, \( I_s \) is the \( s \times s \) identity matrix).
5.1. Phase properties

The dispersion and dissipation are important properties which characterize the numerical behavior of methods constructed for oscillatory problems. Similarly to [50, 18], they can be defined for our proposed EFTDDIRK methods as follows.

**Definition 5.1** (Dispersion and dissipation). With the stability function \( R(i\theta, \omega h) \) given in (5.3), the quantities

\[
\text{Disp} = \theta - \arg(R(i\theta, \omega h)) \quad \text{and} \quad \text{Dis} = 1 - |R(i\theta, \omega h)|
\]

are called the dispersion (phase-lag) and the dissipation (amplification error), respectively. The scheme (2.1) is dispersive of order \( p \) and is dissipative of order \( q \) if

\[
\text{Disp} = C_{p+1}(r)\theta^{p+1} + O(\theta^{p+3}), \quad \text{Dis} = C_{q+1}(r)\theta^{q+1} + O(\theta^{q+3}),
\]

respectively (here \( r = \frac{\omega h}{\theta} \)). In the case \( \text{Disp} = 0 \) or \( \text{Dis} = 0 \), it is called zero-dispersive or zero-dissipative, respectively.

Using (5.4), in Table 2 we derive the dispersion and dissipation for the EFTDDIRK methods constructed in Section 4.

| Method                 | Dispersion Disp(\(\theta\)) | Dissipation Dis(\(\theta\)) |
|------------------------|------------------------------|-----------------------------|
| EFTDDIRK2s4(\(\theta\), \frac{1}{4}, \phi) | \(\frac{1}{380}(-11 + 20\phi)(1 - r^2)\theta^5 + O(\theta^7)\) | \(\frac{1}{23040}(-230 + 360\phi - 7r^2)(1 - r^2)\theta^6 + O(\theta^8)\) |
| EFTDDIRK2s4(0, \frac{1}{2}, \phi)        | \(\frac{1}{240}(-3 + 40\phi)(1 - r^2)\theta^5 + O(\theta^7)\) | \(\frac{1}{7000}(-50 + 720\phi - r^2)(1 - r^2)\theta^6 + O(\theta^8)\) |
| EFTDDIRK2s5                        | \(\frac{(1-r^2)((168\sqrt{5}-379)r^2+84\sqrt{5}-162)}{252000}(1-r^2)\theta^7 + O(\theta^9)\) | \(\frac{(r^4+r^2-2)}{14400}\theta^6 + O(\theta^8)\) |
| EFTDDIRK3s6                | \(\frac{(1-r^2)((17\sqrt{5}-10)r^2-4\sqrt{5}-10)}{3280(5+\sqrt{5})^4}\theta^7 + O(\theta^9)\) | \(\frac{(1-r^2)((15+\sqrt{5})r^4+175(5\sqrt{5}-9)r^2-175(1+3\sqrt{5})}{15120000(3+\sqrt{5})^3}\theta^8 + O(\theta^{10})\) |

Table 2: Dispersion and dissipation of the newly derived EFTDDIRK methods.
In view of Table 2, it is easy to see that by choosing $\phi = \frac{11}{20}$ and $\phi = \frac{3}{40}$, the phase-lag for EFTDDIRK2s4(0, 0, $\phi$) and EFTDDIRK2s4(0, 0, $\phi$) is optimized and increased to order six, respectively. In Section 7, we demonstrate the efficiency of these optimized methods over non-optimized phase-lag methods (which we simply take $\phi = 0$).

5.2. Region of imaginary stability

One can also study the imaginary stability region of the proposed EFTDDIRK methods similarly to [50, 18].

**Definition 5.2 (Imaginary stability region).** The region of imaginary stability $S$ of the EFTDDIRK methods (2.1) is given by

$$S = \{(\theta, \omega h) \mid \theta > 0, \omega > 0, |R(i\theta, \omega h)| \leq 1\}.$$

![Figure 1: Imaginary stability plots for the newly derived EFTDDIRK methods](image)

In Figure 1, we plot the imaginary stability regions in the $\theta - \omega h$ plane on $[0, 5]^2$ (see the shaded regions) of the newly constructed EFTDDIRK methods. For a fixed value of $\omega h$, one can determine a sequence of the imaginary
stability intervals for each EFTDDIRK method (by finding the intersection of the horizontal line passing through \( \omega h \) acrossing the shaded region). It is observed from Figure 1 that the optimized methods EFTDDIRK2s4\((\frac{1}{4}, 1, \frac{11}{20})\) and EFTDDIRK2s4\((0, \frac{1}{2}, \frac{3}{10})\) have larger imaginary stability regions than their non-optimized phase-lag counterparts EFTDDIRK2s4\((\frac{1}{4}, 1, 0)\) and EFTDDIRK2s4\((0, \frac{1}{2}, 0)\), respectively. The sixth-order method EFTDDIRK3s6 has the largest stability region. In fact, it has the largest sequence of imaginary stability intervals even for larger values of \( \omega h \).

6. A note on frequency estimation

In view of the constructed EFTDDIRK schemes, it is crucial to determine the principal frequency \( \omega \) (in turn \( \mu = i \omega h \)) for their implementation. This was a challenging aspect of the numerical integration of initial value problems with exponentially/trigonometrically based methods, especially when the frequency is not known in advance. In [31], a strategy was derived for estimating the frequency of the system based on the leading term of the local truncation error. This approach has been extended and explored in [50]. Another approach was discussed in [44, 49] to obtain the optimum frequency \( \omega_{opt} \) as a result of minimizing the total energy of nonlinear periodic oscillators. In this work, we apply the strategy presented in [49] for the problem where the fitting frequency is not given. In particular, the golden section search technique [43] is utilized to obtain the optimum frequency \( \omega_{opt} \) based on minimizing the error of the method for a given interval around the angular frequency.

7. Numerical experiments

In this section, we evaluate the effectiveness of the newly constructed EFTDDIRK methods of orders 4, 5, and 6 when compared to existing implicit methods of the same orders in the literature. Our numerical experiments are carried out on a list of three oscillatory test problems (see below) and implementations are performed in MATLAB on a single workstation using an 8GB RAM processor Intel(R) Core(TM) i5-8250U CPU @ 1.80GHz Laptop. The internal stages of the DIRK methods are sequentially computed by using the fixed point iteration technique. Numerical investigation include accuracy and efficiency comparisons. For accuracy comparisons, all methods use the same set of stepsizes. For efficiency comparisons, however, the stepsizes are
chosen such that all the considered methods achieve the same error thresholds (measured based on the maximum global error \(\log_{10}(MGE)\)). When the exact solution is unknown, the reference solution is computed by using the sixth-order method EFTDDIRK3s6 with sufficient small stepsize. For the readers’ convenience, we list the evaluated methods in two groups as follows.

**Methods of Order 4**
- SymDIRK: symmetric 5-stage DIRK method [19].
- Gauss2: Gauss 2-stage implicit RK method [9].
- TDFIRK2s4: 2-stage two-derivative implicit RK method [13].
- TDDIRK2s4: 2-stage two-derivative DIRK method [4].
- EFTDDIRK2s4\((c_1, c_2, \phi)\): new 2-stage EFTDDIRK method of order 4.

**Methods of Order 5 and 6**
- TDFIRK3s5: 3-stage implicit two-derivative RK method of order 5 [13].
- Gauss3: Gauss 3-stage implicit RK method of order 6 [9].
- TDDIRK3s5: 3-stage two-derivative DIRK method of order 5 [4].
- TDDIRK4s6: 4-stage two-derivative DIRK method of order 6 [4].
- EFTDDIRK2s5: new 2-stage EFTDDIRK method of order 5.
- EFTDDIRK3s6: new 3-stage EFTDDIRK method of order 6.

**Example 1 (perturbed Kepler’s problem).** Consider the Hamiltonian system studied in [21]

\[
H(p, q) = \frac{1}{2}(p_1^2 + p_2^2) + \frac{\omega^2}{2}(q_1^2 + q_2^2) + \frac{\alpha}{6}(q_1^2 + q_2^2)^3, \tag{7.1}
\]

with the initial data

\[
q_1(0) = 1, \quad q_2(0) = 0, \quad p_1(0) = 0, \quad p_2(0) = \omega + \epsilon,
\]
where \( \alpha = \epsilon(2\omega + \epsilon) \). The analytic solution is given by

\[
q_1(t) = \cos((\omega + \epsilon)t), \quad p_1(t) = -(\omega + \epsilon) \sin((\omega + \epsilon)t),
\]
\[
q_2(t) = \sin((\omega + \epsilon)t), \quad p_2(t) = (\omega + \epsilon) \cos((\omega + \epsilon)t),
\]

representing a periodic motion. In this experiment, we have chosen the parameter values \( \epsilon = 10^{-2}, \omega = 5 \), and the integration is carried out on the interval \([0, 100]\). For accuracy comparisons, the same set of stepsizes \( \{h = \frac{1}{j}, j = 3, 4, 5, 6\} \) is used for all the considered integrators. The numerical results are presented in Figures 2 and 3 which also show the efficiency plots (the step sizes are chosen in such a way that the same error thresholds are achieved). As seen from the left diagrams of these figures, all the new methods fully achieve their orders of convergence (4, 5, and 6).

Figure 2: Accuracy (left) and efficiency (right) plots of 4th-order methods for Example 1. For comparison, a straight line with slope 4 is added.
Figure 3: Accuracy (left) and efficiency (right) plots of 5th and 6th-order methods for Example 1. For comparison, straight lines with slopes 5 and 6 are added.

It can be seen from Figure 2 that the methods whose dispersion were optimized (EFTDDIRK2s4(1/4, 1, 14),12,14) and EFTDDIRK2s4(0, 1/2, 3/40) clearly outperform the other methods of order 4. Figure 3 shows (right) that the newly derived methods EFTDDIRK2s5 (order 5) and EFTDDIRK3s6 (order 6) derived in this work are much more accurate and faster when compared to the considered existing methods of order 5 and 6.

**Example 2 (Fermi-Pasta-Ulam problem).** Next, we consider the highly oscillatory Fermi-Pasta-Ulam (FPU) problem (see [27]) including \( m \) stiff springs, in which the motion is described by a second-order system of differential equations of the form

\[
\ddot{x}(t) + \Omega^2 x(t) = -\nabla U(x(t)), \quad t \in [t_0, t_{end}],
\]

where

\[
\Omega = \begin{bmatrix}
0_{m \times m} & 0_{m \times m} \\
0_{m \times m} & \omega I_{m \times m}
\end{bmatrix}
\]

and \( \omega \gg 1 \),

and \( U(x) \) is a smooth nonlinear potential function given by

\[
U(x) = \frac{1}{4} \left[ (x_1 - x_{m+1})^4 + \sum_{j=1}^{m-1} (x_{j+1} - x_{m+j-1} - x_j - x_{m+j})^4 + (x_m + x_{2m})^4 \right]
\]
with \( x_j = x_j(t) \) represents for positions of the \( j \)th stiff spring. As in [27], we consider the case for \( m = 3 \), and choose

\[
x_1(0) = 1, \quad \dot{x}_1(0) = 1, \quad x_4(0) = \omega^{-1}, \quad \dot{x}_4(0) = 1,
\]

and zero for the remaining initial values. The system is integrated on \([0, 100] \) with \( \omega = 50 \).

Note that the FPU problem (7.2) can be also described by the Hamiltonian system with total energy

\[
H(x, \dot{x}) = \frac{1}{2} \|\dot{x}\|^2 + \frac{1}{2} \|\Omega x\|^2 + U(x),
\]

(7.3)

where \( x \) and \( \dot{x} \) expresses the scaled displacements and velocities (or momenta), respectively. Therefore, the exact value of the total energy is \( H(x_0, \dot{x}_0) = \frac{1}{2}(\sqrt{2})^2 + \frac{1}{2}(1^2) + (0.501200080) = 2.001200080 \).

While the left diagrams of Figures 4 and 5 show the accuracy comparisons (using the same set of step sizes \( \{h = 1/2^j, \; j = 6, 7, 8, 9\} \) for each method), the right diagrams display the efficiency evaluations, in which the step sizes are chosen in such a way that the same error thresholds are achieved.

Figure 4: Accuracy (left) and efficiency (right) plots of 4th-order methods for Example 2.
Figure 5: Accuracy (left) and efficiency (right) plots of 5th and 6th-order methods for Example 2.

Among methods of order 4, one can see again that the new method $EFTDDIRK2s4(0, \frac{1}{2}, \frac{3}{40})$ is the most accurate and efficient. Also, the newly derived fifth- and sixth-order methods $EFTDDIRK2s5$ and $EFTDDIRK3s6$ are more accurate and efficient compared to some existing methods of the same order, respectively.

Next, we investigate the preservation of the Hamiltonian for the FPU system by some selected methods of orders 4, 5, and 6. Figure 6 presents the absolute error of the Hamiltonian ($|H_N - H_0|$) versus time using stepsize $h = \frac{1}{200}$, where $H_N$ is the computed Hamiltonian after $N$ steps.

Figure 6: Hamiltonian errors of 4th-order (left), 5th- and 6th-order (right) methods for Example 2.
It is observed that the fourth-order methods are less accurate than Gauss2 method. However, the newly derived fifth- and sixth-order methods EFTDDIRK2s5 and EFTDDIRK3s6 preserve the total energy much better than the existing methods of the same order, respectively.

**Example 3 (the Sine-Gordon equation).** Lastly, we consider the sine-Gordon equation with periodic boundary condition \[ u (-1, t) = u (1, t). \] (7.4)

A semi-discretization in the spatial variable by the second-order centered finite difference method leads to the following system of ODEs

\[
\frac{d^2 U}{dt^2} + MU = F(U), \quad 0 < t \leq t_{\text{end}}, \quad (7.5)
\]

where \( U(t) = (u_1(t), \ldots, u_N(t))^T \) with \( u_i(t) = u(x_i, t), \) \( i = 1, \ldots, N. \) Equation (7.5) can be further transformed to a system of first order DEs given by

\[
\frac{d}{dt} \begin{bmatrix} U \\ V \end{bmatrix} = \begin{bmatrix} 0 & I \\ -M & 0 \end{bmatrix} \begin{bmatrix} U \\ V \end{bmatrix} + \begin{bmatrix} 0 \\ F(U) \end{bmatrix}, \quad 0 < t \leq t_{\text{end}}. \quad (7.6)
\]

Here, \( V = U' \), \( I \) is the \( N \times N \) identity matrix, \( 0 \) is the \( N \times N \) zero matrix, \( \bar{0} \) is a zero column vector of size \( N \times 1, \)

\[
M = \frac{1}{\Delta x^2} \begin{pmatrix}
2 & -1 & -1 \\
-1 & 2 & -1 \\
& \ddots & \ddots & \ddots \\
& & -1 & 2 & -1 \\
& & & -1 & -1 & 2
\end{pmatrix}
\]
(with $\Delta x = 2/N$, $x_i = -1 + i\Delta x$, $i = 1, 2, \ldots, N$), and $F(U) = -\sin(U) = -\left(\sin u_1, \ldots, \sin u_N\right)$T. As in [20], we use the initial conditions

$$U(0) = (\pi)^N_{i=1}, \quad V(0) = \sqrt{N} \left(0.01 + \sin\left(\frac{2\pi i}{N}\right)\right)^N_{i=1},$$

($N = 64$) and integrate the problem on the interval $[0, 10]$.

Figure 7: Accuracy (left) and efficiency (right) plots of 4th-order methods for Example 3.

Again, on the left side of Figure [7] we display accuracy plots using the same set of stepsizes $h = 1/2^i$, $i = 4, 5, 6, 7$, and the efficiency plots are
shown on the right side (different time step sizes were chosen so that all the compared methods attain about the same level of accuracy).

The numerical results show that $EFTDDIRK2s4(0, rac{1}{2}, 0)$ is the least accurate among tested methods. This can be explained by the fact that its first stage is computed explicitly (since $c_1 = 0$) and thus the accuracy is sensitive when applied to the large ODE system (7.6) resulted from the spatial discretization of the PDE (7.4). It is also the slowest method (its efficiency plot even does not show up in the right diagram of Figure 7). One can also see that $EFTDDIRK2s4(\frac{1}{4}, 1, 0)$ performs about the same as the other fourth-order methods. All other newly derived EFTDDIRK methods, however, are much more accurate and efficient than existing methods of the same orders.

8. Conclusion

We have derived a class of exponentially fitted two-derivative diagonally implicit Runge–Kutta (EFTDDIRK) methods for solving oscillatory differential equations. New order and exponential fitting conditions are obtained, leading to the derivation of new methods of orders 4, 5, and 6. Stability and phase-lag analysis of these methods were investigated which resulted in optimized fourth-order schemes that are much more accurate and efficient. Our numerical experiments have confirmed the efficiency and accuracy of these new EFTDDIRK methods when compared to standard implicit (two-derivative) Runge–Kutta methods of the same orders.

Future works will be focusing on the existence of symmetric EFTDDIRK methods for symplectic, Hamiltonian or reversible systems. Also, we will consider the two-derivative singly diagonally implicit methods with a view to practical applications because of the easy implementation structure as discussed in [9] and [34].
