Abstract. In this report, silicon quantum dots (SiQDs) with the NH$_2$ functional group were synthesized with the hydrothermal method. The as-prepared SiQDs exhibit a strong fluorescence emission peak at 441 nm when excited at 355 nm and are effectively quenched upon adding Cr$^{6+}$ ions. Hence, SiQDs were used as an optical probe to detect Cr$^{6+}$ ions in solutions. The crystal structure of SiQDs was characterized by using X-ray diffraction (XRD). The Fourier-transform infrared spectroscopy (FT-IR) was used to determine the linker groups on the SiQDs surface. The fluorescence spectroscopic technique with an excitation wavelength of 355 nm was used to quantify the Cr$^{6+}$ ion concentration in the solutions in the range of 0.1–1000 μM. Competition from common coexisting ions, such as K$^+$, Na$^+$, Al$^{3+}$, Zn$^{2+}$, and Pb$^{2+}$, was ignorable. The test with actual samples showed good linearity for the Cr$^{6+}$ concentration range of 0.1–50 μM.

Keywords: Cr$^{6+}$ ion, fluorometric detection, Si quantum dots, SiQDs, optical probe, hydrothermal method

1 Introduction

Over the past decades, the increasing toxicity of heavy metals has seriously affected the environment. One of those heavy metals is chromium, which exists in different oxidation states. Trivalent chromium (Cr$^{3+}$) and hexavalent chromium (Cr$^{6+}$) are primary oxidation states in the environment. Cr$^{6+}$ ions have a stronger impact on human health and the environment than Cr$^{3+}$ ions because of its high solubility, carcinogenicity, mutagenicity, and teratogenicity in biological systems [1]. While Cr$^{6+}$ exists primarily as highly soluble oxyanions [2], Cr$^{6+}$ is less soluble and readily precipitates as Cr(OH)$_3$. Cr$^{6+}$ has low toxicity and is considered an essential nutrient for many organisms [3]. In contrast, Cr$^{6+}$ is 1000-fold more toxic than Cr$^{3+}$ [4]. Nevertheless, the Cr$^{6+}$ ion and other Cr$^{6+}$ ion forms are used in different industries, including leather tanning, electroplating, painting, and metallurgy [1]. Therefore, chromium contamination has been reported in various industrial sites because of accidental leakages or improper disposal [6-9]. Hence, the determination of total chromium is crucial for environmental impact studies.
Recently, quantum dots (QDs) have attracted much attention because of their unique physical and optical properties, such as strong absorption, high quantum yield, fluorescence emission, availability for resizing by adding functional groups in the nanoscale, and high stability [10]. However, toxic inorganic precursors are commonly used in synthesizing traditional QDs and may harm various biological systems [11]. Among the quantum dots, those of silicon, semiconductor Si nanoparticles ranging from 1 to 10 nm, have attracted much attention in analytical science because of their advantages, such as inertness, nontoxicity, abundance, and low cost [12]. In addition, their highly efficient fluorescence makes them promising optical probes for various biomedical and biological applications [13].

In this paper, the silicon quantum dots (SiQDs) with NH₂ functional groups, synthesized with the hydrothermal method, were used as an optical probe for detecting Cr⁶⁺ ions in solutions via the fluorescence quenching mechanism. Their structure and fluorescence properties were also addressed.

2 Experimental

2.1 Synthesis of SiQDs solution

All reagents used in the experiments were purchased from Sigma-Aldrich in the analytical grade without further purification. First, 1 g of trisodium citrate (TSC) was completely dissolved in 30 mL of deionized water (DI) in a Teflon cup under magnetic stirring and aerated simultaneously with high-purity nitrogen to purge dissolved oxygen for 30 minutes. Next, 3 mL of 3-aminopropyl triethoxysilane (APTES) was added to the solution. The mixture was continuously stirred and aerated with nitrogen for five minutes. Afterwards, the Teflon cup was put in a stainless steel vessel, tightened, and covered with foil. The system was heated for 12 hours at 170 °C under magnetic stirring with a speed of 450 rpm. Finally, a SiQDs solution with yellowish colour was obtained. The synthesis schema of the stock SiQDs solution is shown in Fig. 1. From the obtained SiQDs solution, we prepared derivative SiQDs solutions for subsequent experiments by diluting it at the 1:300, 1:600, and 1:1200 (v/v) ratios. After dilution, these derivative SiQDs solutions strongly emitted a blue colour when excited with UV light of a 365 nm wavelength. The derivative SiQDs solution at the 1:600 dilution ratio was selected for the subsequent measurements.

2.2 Preparation of Cr⁶⁺ solutions

The 100 mM Cr⁶⁺ solution was obtained by dissolving 147.092 g potassium dichromate (K₂Cr₂O₇) in 10 mL of DI water and then used as the first stock solution. Firstly, the derivative stock solutions with a concentration of 0.1, 1, 10, and 100 mM were prepared by diluting the first stock solution with an appropriate volume of DI water. Secondly, the Cr⁶⁺ ion solutions of different final concentrations were also prepared by diluting a specific volume of appropriate derivative stock solutions with a relevant volume of DI water. The concentration of these final Cr⁶⁺ ion solutions is shown in the first column of Table 1.
Table 1. Volume of Cr$^{6+}$ ion solutions (μL)

| Final Solutions | Derivate Stock Solution |
|-----------------|-------------------------|
|                 | Cr$^{6+}$ (100 mM) | Cr$^{6+}$ (10 mM) | Cr$^{6+}$ (1 mM) | Cr$^{6+}$ (0.1 mM) | DI H$_2$O |

2.3 Preparation of actual samples

Some actual samples were taken from Van Phuc village, the To Lich river, and the Nguyen Lan river, and they were subjected to sedimentation for 12 hours. Then, they were transferred into 1 mL glass vessels and named VP1, VP2, VP3, TL1, TL2, TL3, TL4, TL5, NL1, and NL2 according to where they were collected (Van Phuc village, the To Lich river, and the Nguyen Lan river). Afterwards, a solution containing Cr$^{6+}$, K$^+$, Na$^+$, Al$^{3+}$, Zn$^{2+}$, and Pb$^{2+}$ ions was dropped into each glass vessel. The obtained actual samples are shown in the first three columns of Table 2.
Table 2. Volume of wastewater samples (μL)

| Van Phuc village | To Lich river | Nguyen Lan river | Cr$^{6+}$ (5 mM) | Cr$^{6+}$ (100 mM) | K$^+$ (20 mM) | Na$^+$ (20 mM) | Al$^{3+}$ (20 mM) | Zn$^{2+}$ (20 mM) | Pb$^{2+}$ (20 mM) |
|------------------|--------------|------------------|-------------------|-------------------|------------|-------------|----------------|----------------|-----------------|

| TL5              | 885          |                  | 35                | 20                | 10         | 20          | 10              | 10              | 20              |
| NL1              | 1000         |                  |                   |                   |            |             |                |                |                 |
| NL2              | 965          |                  | 15                | 10                | 10         | 10          |                 |                 |                 |

2.4 Instrumentation

The crystalline phase of the SiQDs was characterized by using X-ray diffraction (XRD) on an XRD Siemens D5005 diffractometer with Cu-Kα radiation ($2θ = 10â€“80°$, step 0.02°). Fluorescence spectra were measured on a spectrofluorometer FL 3-22, Jobin Yvon-Spix, USA. FT-IR spectra were recorded with a wave number range of 375–4000 cm$^{-1}$ on a Jasco 4600 Fourier-transform spectrophotometer. All the measurements were carried out at ambient temperature.

3 Results and discussions

The X-ray diffraction pattern of SiQDs is shown in Fig. 2. We can see that the broad diffraction peak at 22° is unclear and disturbed.

The deconvolution of the X-ray diffraction pattern reveals the presence of the peaks assigned to amorphous SiO$_2$ (at approximately 22° – the red curve) and crystal plane (111) of crystal Si (at approximately 28° – the green curve) [14]. The crystalline grain size calculated from the Scherrer formula for this crystal plane is 0.34 nm (green curve).

The absorption spectrum of SiQDs is presented in Fig. 3. A typical absorption band centred at about 236 nm can be attributed to the $\pi-\pi^*$ transitions of N–SiQDs bonds [15]. Fig. 4 displays the FT-IR spectra of SiQDs and APTES in...
the ranges of 375–2000 cm\(^{-1}\) (Fig. 4a) and 2000–4000 cm\(^{-1}\) (Fig. 4b). The FT-IR spectrum of SiQDs reveals the existence of the C–H, O–Si–O, –NH\(_2\), and Si–O–Si bonds in both APTES and SiQDs samples. The peak at 470 cm\(^{-1}\) is attributed to the bending vibrations of O–Si–O (14). Strong N–H bending vibrations at 1590 cm\(^{-1}\) and 3370 cm\(^{-1}\) (Fig. 4a, 4b, bottom) indicate the presence of the –NH\(_2\) group on the SiQDs surface. Thanks to the presence of the –NH\(_2\) group, SiQDs are well dispersed in water. Furthermore, the peak at 3370 cm\(^{-1}\) appears in the APTES spectrum (Fig. 4b, up) with a weaker intensity than the one in the SiQDs spectrum (Fig. 4b, bottom) because the vibration of the –NH\(_2\) bond appears more clearly in SiQDs.

Fig. 5a displays the excitation and fluorescence spectra of SiQDs, and Fig. 5b demonstrates the fluorescence spectra of SiQDs solution with different Cr\(^{6+}\) ion concentrations. The characteristic absorption peak at 355 nm reveals that the synthesized SiQDs are uniformly dispersed [16]. The maximal emission intensity of SiQDs is observed at 441 nm. Similarly, as shown in the inset of Fig. 5a, the SiQDs are transparent in daylight and emit intense blue colour under the illumination of UV irradiation at 365 nm. Furthermore, the stability of SiQDs is confirmed by the fluorescence spectra of SiQDs at different intervals. The as-synthesized SiQDs are stable even after two-month storage at \(-10^\circ\)C. In contrast, H\(_2\)O and other Cr\(^{6+}\) solutions emit primarily at a wavelength of 396 nm. The emission peak at the 452 nm wavelength is weak or absent (Fig. 5b).

The qualitative result of Cr\(^{6+}\) ion detection is shown in Fig. 6. The colour images of the samples containing Cr\(^{6+}\) ion in the range of 1–1000 μM were taken under daylight (Fig. 6a) and UV light with a wavelength of 365 nm (Fig. 6b). Notably, the fluorescence intensity of the SiQDs solutions decreases remarkably with increasing Cr\(^{6+}\) concentration. The fluorescence spectra in Fig. 7 demonstrate that all peaks localize at the 441 nm wavelength. Their intensity decreases with increasing Cr\(^{6+}\) concentration, indicating that Cr\(^{6+}\) possibly forms complexes with SiQDs.
Fig. 5. Excitation and fluorescence spectra of SiQDs (a) and fluorescence spectra of added Cr$^{6+}$ ion solutions (b)

(b)

Fig. 6. Fluorescence of Cr$^{6+}$ solutions corresponding to concentrations in the range of 1–1000 μM under daylight (a) and UV irradiation with wavelength of 365 nm (b)

Fig. 7. Fluorescence spectra of SiQDs solutions (1:1200) with Cr$^{6+}$ ion solutions with concentration in the range of 0.1–1000 μM

Under UV illumination (365 nm), electrons move from the valence band to the conduction band in SiQDs. Some of them might recombine with holes in the valence band and emit a photon. Others might combine with N atoms. Hence, the N atoms become more mobile. When the Cr$^{6+}$ ions are present, the nitrogen atoms transfer these electrons to them, forming complexes between the SiQDs and the Cr$^{6+}$ ions. Thus, the peak intensity in the fluorescence spectra of the SiQDs decreases with increasing Cr$^{6+}$ ion concentration. The mechanism of the fluorescence quenching is shown in Fig. 8.
Fig. 8. Mechanism of the SiQDs fluorescence quenching

Fig. 9 illustrates the dependence of fluorescence intensity on Cr\textsuperscript{6+} ion concentration in the solutions of the SiQDs probes. It can be seen that the fluorescence intensity increases with the increasing concentration of the SiQDs. Probe 1:300 is the most sensitive, and probe 1:1200 reaches saturation rapidly. According to the linearity of the standard curve in the range of 0.1–50 µM, we chose probe 1:1200 for detecting Cr\textsuperscript{6+} ions in actual samples.

Fig. 9 displays the fluorescence intensity at 441 nm in the absence (F\textsubscript{0}) and presence (F) of Cr\textsuperscript{6+} of different SiQDs probes added different concentrations of Cr\textsuperscript{6+} ion

Fig. 10 shows the selectivity of the SiQDs optical probe to Cr\textsuperscript{6+}, K\textsuperscript{+}, Na\textsuperscript{+}, Al\textsuperscript{3+}, Zn\textsuperscript{2+}, and Pb\textsuperscript{2+} in the solutions with a concentration of 200 µM. It can be noticed that the SiQDs optical probe reaches the best sensitivity to the Cr\textsuperscript{6+} ion.

Fig. 11 displays the fluorescence spectra of the actual samples. It is obvious that increasing the Cr\textsuperscript{6+} ion concentration leads to a decrease in the fluorescence signal in the VPs and TLs groups. The fluorescence intensity of the TL5 sample decreases substantially, corresponding to the most added Cr\textsuperscript{6+} amount. The calibration curve is linear for Cr\textsuperscript{6+} ion concentrations (R\textsuperscript{2} = 0.998) from 0.1 to 50 µM (Fig. 12). The actual and determined Cr\textsuperscript{6+} ion concentration is approximately the same (Tab. 3). Hence, the optical probe can detect the Cr\textsuperscript{6+} ion concentration in actual samples.

4 Conclusion

We successfully synthesized SiQDs with surface functionalization. The SiQDs optical probe exhibited high sensitivity towards Cr⁶⁺ ions and was used to detect and qualify actual samples. The method has good linearity in the range of 0.1–50 µM.
