Abstract. Consider a complex Hamiltonian system and an integral curve. In this paper, we give an effective and efficient procedure to put the variational equation of any order along the integral curve in reduced form provided that the previous one is in reduced form with an abelian Lie algebra. Thus, we obtain an effective way to check the Morales-Ramis-Simó criterion for testing meromorphic Liouville integrability of Hamiltonian systems.

1. Introduction

Consider a Hamiltonian system of $2n$ differential equations

$$(X_H) : \begin{cases}
\dot{q}_i = +\frac{\partial H}{\partial p_i} \\
\dot{p}_i = -\frac{\partial H}{\partial q_i}
\end{cases}$$

A first integral is a function of the $q_i$ and $p_i$ which is constant along the solutions of $(X_H)$. The system is called (meromorphically) Liouville integrable (or completely integrable) when it admits $n$ (meromorphic) first integrals $F_1, \ldots, F_n$ which are functionally independent (their differentials are linearly independent) and in involution (their Poisson brackets vanish or, equivalently, the associated Hamiltonian vector fields $X_{F_i}$ commute). We refer to the reference books [AM78, CB97, Aud08] for more on this topic; see also Section 2 for definitions.

The Ziglin-Morales-Ramis theory (see [MRR10, Aud08] for statements and applications) provides mathematical tools to check when a system is non-integrable. This is particularly useful as Hamiltonian systems generally come as parametrized families. The non-integrability criteria allow one to discard the vast majority of values of the parameters for which the system is not integrable. The principle is as follows. First, we find a particular solution $\Gamma$ of the system $(X_H)$ (generally from an invariant plane found from symmetries) and we compute variational equations (VE$_p$), i.e. systems of
EFFECTIVE MORALES-RAMIS-SIMÓ THEOREM

linear differential equations governing a Taylor expansion of a solution of \((X_H)\) along the particular solution \(\Gamma\). The Liouville integrability of \((X_H)\) induces integrability conditions on the variational equations \((V\!E_p)\), which in turn imply properties of their monodromy or differential Galois groups. Technically, the Morales-Ramis-Simó theorem states that if \((X_H)\) is integrable, then the Lie algebras of the differential Galois groups of all variational equations \((V\!E_p)\) must be abelian (all these terms are defined in Section 2).

The strength of this criterion is that it turns a geometric condition (integrability) into an algebraic one (abelianity of a Lie algebra), thus paving the way for possible computations. However, although there exist general algorithms to compute differential Galois groups of reducible systems such as the variational equations \((V\!E_p)\) ([Fen15, Ret14] or [vdH07]), none of them are currently even close to being practical or implemented at this time. Furthermore, the size of the variational equations \((V\!E_p)\) grows fast, so only a method which uses the structure of the system to make it simpler has a chance of being efficient. The main goal of the present paper is to explain how to use the structure of the system to make it simpler, which will allow us to check efficiently whether its Lie algebra is abelian or not.

Over the past decade, several approaches have been devised to concretely apply this Morales-Ramis-Simó integrability criterion.

For Hamiltonians of the form \(H = \sum_{i=1}^{n} \frac{1}{2} p_i^2 + V(q)\), where \(V\) is a potential in \(q\), the first variational equation is often a direct sum of Lamé equations of the form \(y''(x) = (n(n+1)\wp(x) + B) y(x)\), where \(\wp\) denotes the Weierstrass function associated to an elliptic curve. In this case, Morales has elaborated a local criterion to find obstructions to integrability on higher variational equations via local computations (see Lemmas 11 and 12 in [MRR01] Page 79, and Proposition 7, Page 81). Maciejewski, Przybylska and Duval have elaborated techniques to handle variational equations for the case of Hamiltonians with potentials [MP06, DM09, DM14, DM15]; see also the works of Combot and coauthors [Com13, CK12, BCSED14].

Another approach is to determine numerical trajectories and compute numerical monodromies around these. Although it is difficult to obtain rigorous proofs by these methods, they provide surprisingly precise information. They have been developed, for example, by Martinez and Simó [MS09], by Simon and Simó in the Atwood paper [PPR+10], by Simon in the more recent [Sim14a, Sim14b] and by Sahnikov [Sal14, Sal13].

The general strategy for turning numerical evidence into rigorous proofs is to show that a certain commutator is non-zero. This in turn yields calculations of integrals and of residues, which can be achieved algorithmically due to their \(D\)-finiteness. This is used by Martinez and Simó in [MS09] and later systematized by Combot and coauthors, see e.g. [CK12, Com13, BCSED14].

The approach that we develop in this paper follows previous work by two of the authors in [AMCW13, AMW11, AMW12]. We establish a reduction method. Consider the \(p\)-th variational equation \((V\!E_p)\) : \(Y' = A(x)Y\), where the coefficients of \(A(x)\) are in a differential field \(k\). Given an invertible matrix \(P(x)\) (a gauge transformation matrix), performing the linear change of variable \(Z = P(x)Y\) produces an equivalent linear differential system for \(Z\), denoted by \(Z' = P(x)[A(x)]Z\). The principle of reduction methods is to look for a gauge
transformation $P(x)$ such that the resulting system $Z' = P(x)[A(x)]Z$ is “as simplified as possible”.

Let $G$ denote the differential Galois group of $(\text{VE}_p)$ and $\mathfrak{g}$ be the Lie algebra of $G$. Following traditional works of Kolchin and Kovacic, we will say that we have a reduced form when $P(x)[A(x)] \in \mathfrak{g}(k)$ (see Subsection 2.3.3). Despite the apparent technicality of this definition, the Kolchin-Kovacic theory shows why this is a desirable form. This is similar to the Lie-Vessiot-Guldberg theories of reduction of connections (see [BSMR10, BSMR12] for the latter and their connections with the Kolchin-Kovacic theory of reduced forms). Our strategy in this paper is to compute such a reduction matrix $P(x)$ efficiently.

After this reduction process, the Lie algebra $\mathfrak{g}$ is easily read and its abelianity (or not) is given in the process. Furthermore, if $\mathfrak{g}$ is abelian, then this process will have prepared the system to allow an efficient reduction of the next variational equation.

Our strategy can be summarized as follows. The $p$-th variational equation $(\text{VE}_p)$ is a differential system of the form $Y' = A(x)Y$ where $A(x)$ has the form

$$A(x) = \begin{pmatrix} A_1(x) & 0 \\ S(x) & A_2(x) \end{pmatrix}.$$ 

In the Morales-Ramis-Simó situation (see Subsection 2.5), we may assume that the $A_i(x)$ are in reduced form and that the Lie algebra of the differential Galois group of the block diagonal system

$$Y' = A_{\text{diag}}Y, \quad \text{with} \quad A_{\text{diag}} = \begin{pmatrix} A_1(x) & 0 \\ 0 & A_2(x) \end{pmatrix},$$

has an abelian Lie algebra. We show (Theorem 3.3 in Subsection 3.2) that the reduction matrix may be chosen of the form

$$P(x) = \begin{pmatrix} \text{Id} & 0 \\ \sum_i f_i(x)S_i & \text{Id} \end{pmatrix}$$

where Id denotes the identity matrix, where the $S_i$ are easily found from $S(x)$ and where the unknown functions $f_i(x)$ remain to be found. In Subsection 3.3, we show how standard linear algebra allows us to find these $f_i(x)$ as rational solutions of first order linear differential equations $y' = \lambda(x)y + \sum_i c_ib_i(x)$ where the $c_i$ are constant and where $\lambda(x)$ and the $b_i(x)$ are in a convenient field.

**Structure of the paper.** In Section 2, we recall the necessary notions of Liouville integrability of Hamiltonian systems, differential Galois groups, reduced forms of linear differential systems and the Morales-Ramis-Simó integrability condition. This section contains only previously known material. In Section 3, we solve a problem that is interesting in its own right: given a block triangular differential system whose diagonal blocks are in reduced form and have an abelian Lie algebra, we give a practical procedure to put the system into reduced form (and hence compute its differential Galois group). In Section 4, we show how to reduce the Morales-Ramis-Simó condition to the latter problem and thereby provide an effective version of the Morales-Ramis-Simó integrability criterion. In Section 5, we demonstrate the efficiency of the method by computing the reduced form and the differential Galois groups of the first three variational equations on a four
dimensional example, originally considered in [CDMP10].

Acknowledgments. We would like to thank G. Casale, T. Combot, A. Maciejewski, J.-J. Morales, M. Przybylska, J.-P. Ramis and M.F. Singer for inspiring conversations regarding the material elaborated here. This paper was initiated at an EMS conference in Bedlewo and significantly improved in Wuhan where T. Dreyfus and J.-A. Weil were invited by the Chinese Academy of Science and the ANR project q-diff. T. Dreyfus is supported by the Labex CIMI in Toulouse.

2. The Morales-Ramis-Simó Integrability Condition

2.1. Hamiltonian Systems and Liouville Integrability. Let \((M, \omega)\) be a complex analytic symplectic manifold of complex dimension \(2n\) with \(n \in \mathbb{N}^*\). Since \(M\) is locally isomorphic to an open connected domain \(U \subset \mathbb{C}^{2n}\), Darboux’s theorem allows us to choose a set of local coordinates \((q_1, p_1, \ldots, q_n, p_n)\) in which the symplectic form \(\omega\) is expressed as \(J^* = J \cdot \text{Id}_n \cdot J^*\), where \(\text{Id}_n\) denotes the identity matrix of size \(n\). In these coordinates, given a function \(H \in C^2(U) : U \rightarrow \mathbb{C}\) (the Hamiltonian), we define a Hamiltonian system over \(U \subset \mathbb{C}^{2n}\) as the differential equation given by the vector field

\[
X_H := J \nabla H = \sum_{i=1}^{n} \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q_i} - \sum_{i=1}^{n} \frac{\partial H}{\partial q_i} \frac{\partial}{\partial p_i},
\]

(2.1)

Corresponding to the Hamiltonian differential system

\[
\frac{d}{dt} q_i = \frac{\partial H}{\partial p_i}(q, p), \quad \frac{d}{dt} p_i = -\frac{\partial H}{\partial q_i}(q, p), \quad \text{for } i = 1 \ldots n.
\]

Consider a non-punctual integral curve \(\Gamma\) of (2.1). A meromorphic function \(F : U \rightarrow \mathbb{C}\) is called a meromorphic first integral of (2.1) along \(\Gamma\) if it is constant along integral curves in a neighborhood of \(\Gamma\), or equivalently when \(X_H(F) = 0\). Observe that the Hamiltonian is a first integral of (2.1), as we clearly have \(X_H(H) = 0\).

The Poisson bracket \(\{,\}\) of two meromorphic functions \(f, g \in C^2(U)\) is defined by \(\{f, g\} := \langle \nabla f, J \nabla g \rangle\). In the Darboux coordinates, its expression is

\[
\{f, g\} = \sum_{i=1}^{n} \frac{\partial f}{\partial q_i} \frac{\partial g}{\partial p_i} - \frac{\partial f}{\partial p_i} \frac{\partial g}{\partial q_i}.
\]

The Poisson bracket endows the set of first integrals with a structure of Lie algebra. A function \(F\) is a first integral of (2.1) if and only if \(\{F, H\} = 0\), i.e. \(H\) and \(F\) are in involution. Also, note that \(X_{\{F, H\}} = [X_F, X_H]\), so the involution condition means that the associated Hamiltonian vector fields commute.

A Hamiltonian system with \(n\) degrees of freedom is called Liouville integrable by meromorphic first integrals along the integral curve \(\Gamma\) if it possesses \(n\) first integrals (including the Hamiltonian) meromorphic over \(U\) which are functionally independent and in pairwise involution.

2.2. Variational Equations. Among the various approaches to the study of meromorphic integrability of complex Hamiltonian systems, we choose a Ziglin-Morales-Ramis type of approach. Concretely, our starting points are the Morales-Ramis theorem [MRR01] and its generalization, the Morales-Ramis-Simó theorem [MRRS07, MRR10]. These two results give necessary conditions for the meromorphic integrability of Hamiltonian systems. Here, we need to introduce the notion of variational equation of order \(p \in \mathbb{N}^*\) along a non-punctual integral curve of (2.1).
Let \( \Phi(z, t) \) be the flow defined by the equation (2.1). Given a non-punctual integral curve \( \Gamma \) of (2.1) and \( z_0 \in \Gamma \), we let \( \phi(t) := \Phi(z_0, t) \) denote a temporal parametrization of \( \Gamma \). We define the \( p^{th} \) variational equation (VE\(_p^\phi\)) of (2.1) along \( \Gamma \) to be the differential equation satisfied by the \( \xi_j := \frac{\partial^j \Phi(z, t)}{\partial t^j} \) for \( j \leq p \). For instance, the first three variational equations are given by (see \[MRRS07\], §3.4, Equation (14), Page 860):

\[
\begin{aligned}
(\text{VE}_1^p) & : \\
(\text{VE}_2^p) & : \\
(\text{VE}_3^p) & : \\
\end{aligned}
\]

For \( p = 1 \), the first variational equation (VE\(_1^\phi\)) is a linear differential equation

\[
\dot{\xi}_1 = A_1 \xi_1 \text{ where } A_1 := d_{\phi} X_H = J \cdot \text{Hess}_{\phi}(H) \in \mathfrak{sp}(n, \mathbb{C}\langle \phi(t) \rangle),
\]

where \( \mathbb{C}\langle \phi(t) \rangle \) denotes the differential field generated by the coefficients of the parametrization \( \phi(t) \). Higher order variational equations are not linear for \( p \geq 2 \). However, for every (VE\(_p^\phi\)), one can construct an equivalent linear differential system (LVE\(_p^\phi\)) called the linearized \( p^{th} \) variational equation (see \[MRRS07\], §3.4 and \[Sim14b\]). Indeed, (VE\(_p^\phi\)) is linear in \( \xi_p \) and polynomial in the \( \xi_i \) for \( i < p \); however, the \( \xi_i \) for \( i < p \) are solutions of the linear differential system (LVE\(_{p-1}^\phi\)) so that polynomials in the \( \xi_i \) also satisfy linear differential systems, obtained via symmetric powers and tensor constructions. See, for example, §3 of \[AMCW13\] for practical details on these tensor constructions on differential systems.

For example, (VE\(_2^\phi\)) is linear in \( \xi_2 \) and linear in the monomials of degree 2 in \( \xi_1 \), i.e. in the solutions of the second symmetric power system \( Y' = \text{sym}^2(A_1)Y \). Hence the system (LVE\(_2^\phi\)) is lower block-triangular and its diagonal blocks are \( \text{sym}^2(A_1) \) and \( A_1 \). We obtain (see e.g. \[MRR10\], \[AMW11\], \[Sim14b\], \[CW15\]) the following matrices \( A_p \) for the first (LVE\(_2^\phi\)):

\[
A_2(x) = \begin{pmatrix}
\text{sym}^2(A_1(x)) & 0 \\
S_2(x) & A_1(x)
\end{pmatrix},
\]

\[
A_3(x) = \begin{pmatrix}
\text{sym}^3(A_1(x)) & 0 \\
S_3(x) & A_2(x)
\end{pmatrix} = \begin{pmatrix}
\text{sym}^3(A_1(x)) & 0 & 0 \\
S_{3,2}(x) & \text{sym}^2(A_1(x)) & 0 \\
S_{3,1}(x) & S_2(x) & A_1(x)
\end{pmatrix}.
\]

In general, the matrix of (LVE\(_p^\phi\)) is of the form

\[
A_p(x) = \begin{pmatrix}
\text{sym}^p(A_1(x)) & 0 \\
S_p(x) & A_{p-1}(x)
\end{pmatrix}.
\]

In \[Sim14b\], §4.1, Simon provides explicit formulas for these linearized variational equations. In what follows, we will identify (VE\(_p^\phi\)) and (LVE\(_p^\phi\)) and we will just speak of variational equations of order \( p \).

The matrix \( \text{sym}^i(A_1(x)) \) has \( \binom{n+i-1}{n-1} \) rows and columns, so that (LVE\(_p^\phi\)) is a first order linear differential system of \( d_p := \sum_{i=1}^{p} \binom{n+i-1}{n-1} = \binom{n+p}{n} - 1 \) equations. The size \( d_p \) grows fairly fast (polynomially of degree \( n \) in \( p \)) and forbids the use of a generic algorithm to compute on (LVE\(_p^\phi\)). For this reason, we elaborate a specific algorithm which takes advantage of the structure of (LVE\(_p^\phi\)) so that the polynomial growth of the size will become a relatively minor concern.
2.3. Differential Galois Theory and Reduced Forms. We begin this subsection with elements of differential Galois theory. We refer to [PS03] or [CH11] and [Sin09] for details and proofs.

2.3.1. The Base Field. Our base field will be $k := \mathbb{C}(\phi(t))$, the differential field generated by the coefficients of the parametrization $\phi(t)$ (and $\mathbb{C}$ is the field of constants, which is assumed to be algebraically closed). We need to make assumptions about $k$ to elaborate our algorithms. First we assume that $k$ is an effective field, i.e. that one can compute representatives of the four operations $+,-,\times,/ \text{ and one can effectively test whether two elements of } k \text{ are equal, see e.g. } [\text{Sin91}].$ Second, we assume that, given any scalar linear differential equation $L(y(x)) = 0$ where $L(y(x)) := a_n(x)y^{(n)}(x) + a_{n-1}(x)y^{(n-1)}(x) + \cdots + a_1(x)y'(x) + a_0(x)y(x)$, with $a_i(x) \in k$, one can effectively compute a basis of its space of rational solutions, i.e. the solutions which are in the base field $k$. The standard example of such a field would be $k = \mathbb{C}(x)$ with $\mathbb{C} = \mathbb{C}[x]$. Singer showed, in [Sin91], Lemma 3.5, that if $k$ is an elementary extension of $\mathbb{C}(x)$ or if $k$ is an algebraic extension of a purely transcendental Liouvillean extension of $\mathbb{C}(x)$, then $k$ satisfies the above two conditions and hence suits our purposes. He also proved, see Theorem 4.1 in [Sin91], that an algebraic extension of $k$ still satisfies our two assumptions, which will be useful, as reducing the first variational equation may induce algebraic extensions.

2.3.2. Differential Galois Theory. Let us consider a linear differential system of the form $Y'(x) = A(x)Y(x)$, with $A(x) \in \mathcal{M}_n(k)$, that is a square matrix of size $n \in \mathbb{N}^*$ in coefficients in $k$. A Picard-Vessiot extension for $Y'(x) = A(x)Y(x)$ is a differential field extension $K|k$, generated over $k$ by the entries of a fundamental solution matrix and such that the field of constants of $K$ is $\mathbb{C}$. The Picard-Vessiot extension $K$ exists and is unique up to differential field isomorphism.

The differential Galois group $G$ of $Y'(x) = A(x)Y(x)$ is the group of field automorphisms of the Picard-Vessiot extension $K$ that commute with the derivation and leave all elements of $k$ invariant. Let $U(x) \in \text{GL}_n(K)$ be a fundamental solution matrix of $Y'(x) = A(x)Y(x)$ with coefficients in $K$. For any $\varphi \in G$, $\varphi(U(x))$ is also a fundamental solution matrix, so there exists a constant matrix $C_\varphi \in \text{GL}_n(\mathbb{C})$ such that $\varphi(U(x)) = U(x)C_\varphi$. The map $\rho_U : \varphi \mapsto C_\varphi$ is an injective group morphism. An important fact is that $G$, identified with $\text{Im} \rho_U$, may be viewed as a linear algebraic subgroup of $\text{GL}_n(\mathbb{C})$.

Two linear differential equations $Y'(x) = A(x)Y(x)$ and $Y'(x) = B(x)Y(x)$, with $A(x), B(x) \in \mathcal{M}_n(k)$ are said to be equivalent over $k$ (or gauge equivalent over $k$) when there exists $P(x) \in \text{GL}_n(k)$, called a gauge transformation matrix, such that $B(x) = P(x) [A(x)] := P(x)A(x)P^{-1}(x) + P'(x)P^{-1}(x)$.

Note that in this case:

$Y'(x) = A(x)Y(x) \iff [P(x)Y(x)]' = B(x)P(x)Y(x)$. Conversely, if there exist matrices $A(x), B(x) \in \mathcal{M}_n(k)$ and $P(x) \in \text{GL}_n(k)$, such that we have $Y'(x) = A(x)Y(x)$, $Z'(x) = B(x)Z(x)$ and $Z(x) = P(x)Y(x)$, then $B(x) = P(x) [A(x)]$. 

The Lie algebra $\mathfrak{g}$ of the linear algebraic group $G \subset \text{GL}_n(\overline{\mathbb{C}})$ is the tangent space to $G$ at the identity. Equivalently, it is the set of matrices $N$ such that $\text{Id}_n + \epsilon N$ satisfies the defining equations of the algebraic group $G$ modulo $\epsilon^2$.

Part two of the following proposition is known as the Kolchin-Kovacic reduction theorem. A proof can be found in [PS03], Proposition 1.31 and Corollary 1.32. See also [BSMR10], Theorem 5.8.

**Proposition 2.1** (Kolchin-Kovacic reduction theorem). Let us consider the differential system $Y'(x) = A(x)Y(x)$ with $A(x) \in \mathcal{M}_n(\mathbb{k})$. Let $G$ be its differential Galois group and $\mathfrak{g}$ the Lie algebra of $G$.

1. Let $H \subset \text{GL}_n(\mathbb{C})$ be a linear algebraic group and $\mathfrak{h} \subset \mathcal{M}_n(\mathbb{C})$ be its Lie algebra. If $A(x)$ belongs to $\mathfrak{h}(\mathbb{k}) := \mathfrak{h} \otimes \mathbb{C} \mathbb{k}$, then $G$ is contained in a conjugate of $H$.

2. Assume that $\mathbb{k}$ is a $C^1$-field and $G$ is connected. Let $H \supset G$ be a connected linear algebraic group with Lie algebra $\mathfrak{h}$ such that $A(x) \in \mathfrak{h}(\mathbb{k})$. Then, there exists a gauge transformation $P(x) \in H(\mathbb{k})$ such that $P(x)[A(x)] \in \mathfrak{g}(\mathbb{k})$.

### 2.3.3. Reduced Forms of Linear Differential Systems

Let $A(x) \in \mathcal{M}_n(\mathbb{k})$, $G$ be the differential Galois group of $Y'(x) = A(x)Y(x)$ and $\mathfrak{g}$ its Lie algebra.

We say that the system $Y'(x) = A(x)Y(x)$ is in reduced form (or in Kolchin-Kovacic reduced form) when $A(x) \in \mathfrak{g}(\mathbb{k}) = \mathfrak{g} \otimes \mathbb{C} \mathbb{k}$. This section contains a quick survey on reduced forms and their practical use.

Following [WN63], a Wei-Norman decomposition of $A(x)$ is a finite sum of the form

$$A(x) = \sum a_i(x)M_i,$$

where $M_i$ has coefficients in $\overline{\mathbb{C}}$ and the $a_i(x) \in \mathbb{k}$ form a basis of the $\overline{\mathbb{C}}$-vector space spanned by the entries of $A(x)$. The $M_i$ depend on the choice of $a_i(x)$ but the $\overline{\mathbb{C}}$-vector space generated by the $M_i$ is independent of the choice of the $a_i(x)$.

**Definition 2.2.** Let $\text{Lie}(A) \subset \mathcal{M}_n(\mathbb{C})$ denote the Lie algebra generated by the $M_i$. We define $\text{Lie}_{\text{alg}}(A) \subset \mathcal{M}_n(\mathbb{C})$, called the Lie algebra associated to $A$, as the algebraic envelope of the Lie algebra $\text{Lie}(A)$, i.e. as the smallest Lie algebra of a linear algebraic group which contains $\text{Lie}(A)$.

Let $\text{Lie}(A; \mathbb{k}) := \text{Lie}(A)(\mathbb{k}) \subset \mathcal{M}_n(\mathbb{k})$ and $\text{Lie}_{\text{alg}}(A; \mathbb{k}) := \text{Lie}_{\text{alg}}(A)(\mathbb{k}) \subset \mathcal{M}_n(\mathbb{k})$. We see that the system $Y'(x) = A(x)Y(x)$ is in reduced form when $\text{Lie}_{\text{alg}}(A; \mathbb{k}) = \mathfrak{g}(\mathbb{k})$.

These reduced forms have long been studied in the context of inverse problems in differential Galois theory (see [MS02] and references therein). Their use in direct problems is more recent. Blázquez and Morales use them in their studies of Lie-Vessiot systems in [BSMR10] and [BSMR12]. Their application to Morales-Ramis theory is initiated in [AMW12] where Aparicio-Monforte and Weil show how to put the first variational equation in reduced form. In [AMCW13], the same authors with Compoint show that a system is in reduced form if and only if, for any tensor construction $\text{const}(A(x))$ on $A(x)$, any rational or hyperexponential solution of $Y' = \text{const}(A(x))Y$ has constant coefficients.

*A field $\mathbb{k}$ is a $C^1$-field when every non-constant homogeneous polynomial $P$ over $\mathbb{k}$ has a non-trivial zero provided that the number of its variables is more than its degree. For example, $\overline{\mathbb{C}}(x)$ is a $C^1$-field and any algebraic extension of a $C^1$-field is a $C^1$-field.*
Assume that the Hamiltonian vector field

Then

Theorem 2.4

(Morales-Ramis-Simó integrability criterion)

A

Lemma 2.3.

Given \( A(x) \in M_\mathbb{N}(k) \), let \( G \) be the differential Galois group of \( Y'(x) = A(x)Y(x) \) and \( \mathfrak{g} \) be its Lie algebra. Let \( H \) be a connected linear algebraic group whose Lie algebra \( \mathfrak{h} \) satisfies \( \mathfrak{h} = \text{Lie}_{\text{alg}}(A) \). Assume that \( G \) is connected.

Then \( Y'(x) = A(x)Y(x) \) is in reduced form, i.e. \( G = H \) and \( \mathfrak{g} = \mathfrak{h} \), if and only if, for all gauge transformation matrices \( P(x) \) in \( H(k) \), we have \( \mathfrak{h}(k) = \text{Lie}_{\text{alg}}(P[A]; k) \).

Proof. Follows directly from the Kolchin-Kovacic reduction theorem, see Proposition 2.1.

2.4. The Morales-Ramis-Simó Integrability Criterion. We are now in position to state the Morales-Ramis-Simó integrability criterion. See [MRRS07] for a proof and [2] for the definitions.

Theorem 2.4 (Morales-Ramis-Simó integrability criterion). Consider a Hamiltonian vector field \( X_H \) and a non-punctual integral curve \( \Gamma \). For \( p \in \mathbb{N}^* \), let \( G_p \) be the differential Galois group of \( (VE_p^p) \), the \( p \)-th variational equation along \( \Gamma \). Let \( \mathfrak{g}_p \) be the Lie algebra of \( G_p \).

Assume that the Hamiltonian vector field \( X_H \) is Liouville integrable by meromorphic first integrals along the integral curve \( \Gamma \). Then, for all \( p \in \mathbb{N}^* \), \( \mathfrak{g}_p \) is abelian.

2.5. The Strategy for an effective Morales-Ramis-Simó Criterion. We refer to [2.2] and [2.3] for the notations used in this subsection. Let us fix an integer \( p \geq 2 \). The matrix of the \( p \)-th variational equation has the form

\[
A_p(x) = \begin{pmatrix}
\text{sym}^p(A_1(x)) & 0 \\
S_p(x) & A_{p-1}(x)
\end{pmatrix}.
\]

For each \( m \in \{1, \ldots , p\} \), we let \( G_m \) denote the differential Galois group of the \( m \)-th variational equation \( Y'(x) = A_m(x)Y(x) \) and \( \mathfrak{g}_m \) its Lie algebra. For all \( m \in \{1, \ldots , p-1\} \), we assume that we know a gauge transformation matrix \( P_m(x) \) such that \( P_m(x)[A_m(x)] \) is in reduced form, i.e. \( \text{Lie}_{\text{alg}}(P_m[A_m]) = \mathfrak{g}_m \), and we further assume that each \( \mathfrak{g}_m \) is abelian. We let \( A_{m,\text{red}}(x) \) denote the obtained reduced form, that is \( A_{m,\text{red}}(x) := P_m(x)[A_m(x)] \).

Under these hypotheses, we will show in the next section how to put the \( p \)-th variational equation \( A_p(x) \) into reduced form in an efficient way.
Remark 2.5. Our assumptions imply that the first variational equation is in reduced form. This in turn implies that our base field \( \mathbb{k} \) is no longer just \( \mathbb{C}(\phi) \) but may be an algebraic extension of the latter (see [AMCW13]). In the sequel, our base field \( \mathbb{k} \) is the algebraic extension of \( \mathbb{C}(\phi) \) which is needed to put the first variational equation into reduced form. Since an algebraic extension of a \( \mathcal{C}^1 \)-field is a \( \mathcal{C}^1 \)-field, we obtain that \( \mathbb{k} \) is a \( \mathcal{C}^1 \)-field provided that \( \mathbb{C}(\phi) \) is a \( \mathcal{C}^1 \)-field. Consequently, we are allowed to use Proposition 2.7, as soon as \( \mathbb{C}(\phi) \) is a \( \mathcal{C}^1 \)-field. From now on, we assume that \( \mathbb{k} \) is a \( \mathcal{C}^1 \)-field.

Our assumptions also imply (see [AMCW13], Lemma 32, Page 1513) that, for all \( m \in \{1, \ldots, p-1\} \), the differential Galois groups \( G_m \) are connected. Moreover, both the groups \( G_m \) and their Lie algebras \( \mathfrak{g}_m \) are abelian.

Lemma 2.6. The group \( G_p \) is connected.

Proof. This is a direct application of [MRH10], Lemma 10.

As we can see in [AMCW13], Lemma 14, Page 1508,

\[
\text{Sym}^p(P_1(x)) [\text{sym}^p(A_1(x))] = \text{sym}^p(A_{1,\text{red}}(x)).
\]

Also, \( \text{sym}^p(A_{1,\text{red}}(x)) \) is a reduced form of \( \text{sym}^p(A_1(x)) \). Indeed, this follows from [AMCW13], Theorem 1, because any tensor construction on \( \text{sym}^p(A_1(x)) \) is a construction on \( A_1(x) \).

Consider the block-diagonal gauge transformation matrix

\[
Q(x) := \begin{pmatrix}
\text{Sym}^p(P_1(x)) & 0 \\
0 & P_{p-1}(x)
\end{pmatrix}.
\]

Thanks to the above remarks (see also [AM10], § 4.5.2), we find that

\[
Q(x) [A_p(x)] = \begin{pmatrix}
\text{sym}^p(A_{1,\text{red}}(x)) & 0 \\
S(x) & A_{p-1,\text{red}}(x)
\end{pmatrix},
\]

where \( S(x) \) has entries in \( \mathbb{k} \), and the block-diagonal part of \( Q(x) [A_p(x)] \) is in reduced form. Furthermore, \( \text{Lie}_{\text{alg}} \left( \begin{pmatrix}
\text{sym}^p(A_{1,\text{red}}) & 0 \\
0 & A_{p-1,\text{red}}
\end{pmatrix} \right) \) is abelian.

3. Reduction of Linear Differential Systems with a Reduced Abelian Diagonal Part

The previous subsection shows that finding a reduced form for the \( p^{th} \) variational equation now amounts to finding a reduced form for

\[
A(x) := Q(x) [A_p(x)] = \begin{pmatrix}
\text{sym}^p(A_{1,\text{red}}(x)) & 0 \\
S(x) & A_{p-1,\text{red}}(x)
\end{pmatrix} \in \mathcal{M}_n(\mathbb{k}).
\]

The submatrices \( \text{sym}^p(A_{1,\text{red}}(x)) \) and \( A_{p-1,\text{red}}(x) \) belong respectively to \( \mathcal{M}_{n_1}(\mathbb{k}) \) and \( \mathcal{M}_{n_2}(\mathbb{k}) \), with \( n_1 := \binom{n+p-1}{n-1} \) and \( n_2 := \binom{n+p-1}{n} - 1 \).

We have \( A(x) = A_{\text{diag}}(x) + A_{\text{sub}}(x) \), where \( A_{\text{diag}}(x) := \begin{pmatrix}
\text{sym}^p(A_{1,\text{red}}(x)) & 0 \\
0 & A_{p-1,\text{red}}(x)
\end{pmatrix} \)
and \( A_{\text{sub}}(x) := \begin{pmatrix}
0 & 0 \\
S(x) & 0
\end{pmatrix} \). We have seen that \( Y'(x) = A_{\text{diag}}(x) Y(x) \) is in reduced form and \( \text{Lie}_{\text{alg}}(A_{\text{diag}}) \) is abelian. The aim of this section is to show how to use those hypotheses to put the full system \( Y'(x) = A(x) Y(x) \) in reduced form.
3.1. The Diagonal and Off-Diagonal Subalgebras. We refer to §2.3.3 for the notations used in this subsection. Let $M_1, \ldots, M_8 \in \mathcal{M}_n(C)$ be a basis of $\text{Lie}_{\text{alg}}(A_{\text{diag}})$ and let $B_1, \ldots, B_\sigma \in \mathcal{M}_n(C)$ be a basis of $\text{Lie}_{\text{alg}}(A_{\text{sub}})$. We define the vector space $\mathfrak{h} := \text{Lie}_{\text{alg}}(A_{\text{diag}}) \oplus \text{Lie}_{\text{alg}}(A_{\text{sub}})$. Note that $\text{Lie}_{\text{alg}}(A) \subseteq \mathfrak{h}$, and $\mathfrak{h}$ is the Lie algebra of a linear algebraic group. Let us sum up some elementary properties of $\mathfrak{h}$ in the two following lemmas:

Lemma 3.1. Let us consider a matrix \[
\begin{pmatrix}
0 & N_1(x) \\
N_{2,1}(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 \\
N_2(x)
\end{pmatrix}
\in \mathfrak{h}(k) and matrices \[
\begin{pmatrix}
0 & 0 \\
C_1(x) & 0
\end{pmatrix}, \begin{pmatrix}
0 & 0 \\
C_2(x) & 0
\end{pmatrix}
\in \text{Lie}_{\text{alg}}(A_{\text{sub}}; k).
\]

(1) For $(i, j) \in \{1; 2\}^2$, \[
\begin{pmatrix}
0 & 0 \\
C_1(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
C_j(x) & 0
\end{pmatrix} = 0.
\]

(2) The matrix \[
\begin{pmatrix}
N_1(x) & 0 \\
N_{2,1}(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
N_2(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
C_1(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
C_j(x) & 0
\end{pmatrix}
\]

and the Lie bracket

\[
\text{Lie}_{\text{alg}}(A_{\text{sub}}; k) \text{ is an ideal in } \mathfrak{h}(k).
\]

Proof. (1) A straightforward computation shows the first point of the lemma.

(2) We have \[
\begin{pmatrix}
N_1(x) & 0 \\
N_{2,1}(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
C_1(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
N_2(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
C_j(x) & 0
\end{pmatrix} = \begin{pmatrix}
0 & 0 \\
N_2(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
C_1(x) & 0
\end{pmatrix}
\begin{pmatrix}
0 & 0 \\
N_1(x) & 0
\end{pmatrix} \in \mathfrak{h}(k).
\]

We prove that they belong to $\text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$ using that fact that the diagonal blocks of the two matrices are zero. The latter Lie bracket identity also shows that $\text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$ is an ideal in $\mathfrak{h}(k)$.

\[\square\]

Lemma 3.2. For all $B(x) \in \text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$, we have $\exp(B(x)) = \text{Id}_n + B(x)$ and $\log(\text{Id}_n + B(x)) = B(x)$. This induces two bijective maps which are inverses of each other

\[
\exp : \text{Lie}_{\text{alg}}(A_{\text{sub}}; k) \to \{\text{Id}_n + B(x), B(x) \in \text{Lie}_{\text{alg}}(A_{\text{sub}}; k)\}
\]

\[
\log : \{\text{Id}_n + B(x), B(x) \in \text{Lie}_{\text{alg}}(A_{\text{sub}}; k)\} \to \text{Lie}_{\text{alg}}(A_{\text{sub}}; k)
\]

Proof. Let $B(x) \in \text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$. The equality $\exp(B(x)) = \text{Id}_n + B(x)$ is a direct consequence of the first point of Lemma 3.1. The same argument shows that $\log(\text{Id}_n + B(x)) = B(x)$. It follows directly that $\exp$ and $\log$ are bijective on the wished sets and inverses of each other.

\[\square\]

3.2. The Shape of the Reduction Matrix. We refer to §2.3 and §3.1 for the notations and definitions used in this subsection. The aim of this subsection is to prove:
Theorem 3.3. There exists a gauge transformation
\[ P(x) \in \{ \text{Id}_n + B(x), B(x) \in \text{Lie}_{\text{alg}}(A_{\text{sub}}; \mathfrak{k}) \}, \]
such that \( Y'(x) = P(x)[A(x)]Y(x) \) is in reduced form.

Let \( G \) be the differential Galois group of \( Y'(x) = A(x)Y(x) \). By construction, we have \( G = G_p \), where \( G_p \) is the differential Galois group of the \( p \)-th variational equation \( Y'(x) = A_p(x)Y(x) \). Let \( H \) be the connected linear algebraic group with Lie algebra \( \mathfrak{h} \). Before proving Theorem 3.3, we start with a key lemma.

Lemma 3.4. There exists a unipotent gauge transformation \( P(x) \), of the form \( P(x) = \begin{pmatrix} \text{Id}_{n_1} & 0 \\ N(x) & \text{Id}_{n_2} \end{pmatrix} \in H(\mathfrak{k}) \), such that \( Y'(x) = P(x)[A(x)]Y(x) \) is in reduced form.

Proof. Let \( H_A \) be the connected linear algebraic group with Lie algebra \( \text{Lie}_{\text{alg}}(A; \mathfrak{k}) \). We have the inclusions \( G \subseteq H_A \subseteq H \). As \( G = G_p \), Lemma 2.6 shows that \( G \) is connected. So we may use the second point of Proposition 2.1 to obtain the existence of \( \tilde{Q}(x) := \begin{pmatrix} D_1(x) & 0 \\ S_Q(x) & D_2(x) \end{pmatrix} \in H_A(\mathfrak{k}) \) such that the linear differential system
\[ Y'(x) = \tilde{Q}(x)[A(x)]Y(x) \]
is in reduced form. Let \( R(x) := \begin{pmatrix} D_1^{-1}(x) & 0 \\ 0 & D_2^{-1}(x) \end{pmatrix} \in H(\mathfrak{k}) \) so that \( R(x)\tilde{Q}(x) = \begin{pmatrix} \text{Id}_{n_1} & 0 \\ D_2^{-1}(x)S_Q(x) & \text{Id}_{n_2} \end{pmatrix} \in H(\mathfrak{k}) \). Consequently, to prove the lemma, it is sufficient to prove that \( Y'(x) = R(x)\tilde{Q}(x)[A(x)]Y(x) \) is in reduced form. We have to prove that \( \text{Lie}_{\text{alg}}(\tilde{Q}[A]; \mathfrak{k}) = \text{Lie}_{\text{alg}}(R\tilde{Q}[A]; \mathfrak{k}) \). Let \( H_{R\tilde{Q}} \) be the algebraic group whose Lie algebra is \( \text{Lie}_{\text{alg}}(R\tilde{Q}[A]) \). Thanks to the first point of Proposition 2.1 the group \( H_{R\tilde{Q}} \) contains \( G \). Since \( Y'(x) = \tilde{Q}(x)[A(x)]Y(x) \) is in reduced form, \( G \) is an algebraic group whose Lie algebra is \( \text{Lie}_{\text{alg}}(\tilde{Q}[A]) \). This implies that \( \text{Lie}_{\text{alg}}(\tilde{Q}[A]; \mathfrak{k}) \subseteq \text{Lie}_{\text{alg}}(R\tilde{Q}[A]; \mathfrak{k}) \).

Let \( K|\mathfrak{k} \) denote the Picard-Vessiot extension for the equation \( Y'(x) = A(x)Y(x) \) and let \( U(x) := \begin{pmatrix} U_1(x) \\ U_{2,1}(x) \\ U_{2,2}(x) \end{pmatrix} \in \text{GL}_n(K) \), with \( U_i(x) \in \text{GL}_{n_i}(K) \) be a fundamental solution. The elements of \( G \) are of the form \( \begin{pmatrix} G_1 & 0 \\ G_{2,1} & G_2 \end{pmatrix} \in \text{GL}_n(\mathfrak{c}) \), with \( G_i \in \text{GL}_{n_i}(\mathfrak{c}) \). Let \( G_{\text{sub}} \) be the subgroup of elements of \( G \) of the form \( \begin{pmatrix} \text{Id}_{n_1} & 0 \\ G_{2,1} & \text{Id}_{n_2} \end{pmatrix} \).

A direct computation shows that \( G_{\text{sub}} \) is a normal subgroup of \( G \). Therefore, \( G \simeq G_{\text{sub}} \rtimes G/G_{\text{sub}} \). Due to [PS03], Proposition 1.34, (2), \( G_{\text{diag}} := G/G_{\text{sub}} \) is isomorphic to the differential Galois group of \( Y'(x) = A_{\text{diag}}(x)Y(x) \). Let us write \( \tilde{Q}(x)[A(x)] =: \begin{pmatrix} D_1(x)[\text{sym}^p(A_{1,\text{red}}(x))] \\ A_{2,1}(x) \end{pmatrix} \begin{pmatrix} 0 \\ D_2(x)[A_{p-1,\text{red}}(x)] \end{pmatrix} \), for some matrix \( A_{2,1}(x) \) in coefficients in \( \mathfrak{k} \). We use the relation \( G \simeq G_{\text{sub}} \rtimes G_{\text{diag}} \) and the fact that \( Y'(x) = \tilde{Q}(x)[A(x)]Y(x) \) is in reduced form to find that
\[ \text{Lie}_{\text{alg}}(\tilde{Q}[A]; \mathfrak{k}) \simeq \text{Lie}_{\text{alg}} \left( \begin{pmatrix} D_1[\text{sym}^p(A_{1,\text{red}})] \\ 0 \\ A_{2,1} \end{pmatrix} \begin{pmatrix} 0 \\ D_2[A_{p-1,\text{red}}] \end{pmatrix} \right) \oplus \text{Lie}_{\text{alg}} \left( \begin{pmatrix} 0 \\ A_{2,1} \end{pmatrix} \right). \]
A direct computation shows that
\begin{equation}
R(x)\tilde{Q}(x)[A(x)] = \begin{pmatrix}
\operatorname{sym}^p(A_{1,\text{red}}(x)) & 0 \\
D_2^{-1}(x)A_{2,1}(x)D_1(x) & A_{p-1,\text{red}}(x)
\end{pmatrix}.
\end{equation}

By construction,
\[
\operatorname{Lie}_{\text{alg}}(R\tilde{Q}[A]; k) \subseteq \operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
\operatorname{sym}^p(A_{1,\text{red}}) & 0 \\
0 & A_{p-1,\text{red}}
\end{pmatrix}(k) \oplus \operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
0 & 0 \\
D_2^{-1}A_{2,1}D_1 & 0
\end{pmatrix}(k).
\]

Since $D_1(x)$ and $D_2(x)$ are invertible matrices, $\operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
0 & 0 \\
D_2^{-1}A_{2,1}D_1 & 0
\end{pmatrix}(k)$ and
\[
\operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
0 & 0 \\
D_2^{-1}A_{2,1}D_1 & 0
\end{pmatrix}(k)
\]

have the same dimension. Due to the inclusion
\[
\operatorname{Lie}_{\text{alg}}\left(\tilde{Q}[A]; k \right) \subseteq \operatorname{Lie}_{\text{alg}}\left(R\tilde{Q}[A]; k\right)
\]

we obtain that
\begin{equation}
\operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
0 & 0 \\
A_{2,1} & 0
\end{pmatrix}(k) = \operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
0 & 0 \\
D_2^{-1}A_{2,1}D_1 & 0
\end{pmatrix}(k).
\end{equation}

Using the facts that the systems $Y'(x) = A_{\text{diag}}(x)Y(x)$ and $Y'(x) = \tilde{Q}(x)[A(x)]Y(x)$ are in reduced form and $G \simeq G_{\text{sub}} \rtimes G_{\text{diag}}$, we find that
\[
\operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
\operatorname{sym}^p(A_{1,\text{red}}) & 0 \\
0 & A_{p-1,\text{red}}
\end{pmatrix}(k) = \operatorname{Lie}_{\text{alg}}\left(\begin{pmatrix}
D_1[\operatorname{sym}^p(A_{1,\text{red}})] & 0 \\
0 & D_2[A_{p-1,\text{red}}]
\end{pmatrix}(k).
\]

Combined with (3.2), this proves that $\operatorname{Lie}_{\text{alg}}\left(R\tilde{Q}[A]; k \right) \subseteq \operatorname{Lie}_{\text{alg}}\left(\tilde{Q}[A]; k\right)$. Since we have an inclusion $\operatorname{Lie}_{\text{alg}}\left(\tilde{Q}[A]; k \right) \subseteq \operatorname{Lie}_{\text{alg}}\left(R\tilde{Q}[A]; k\right)$, we obtain the equality
\[
\operatorname{Lie}_{\text{alg}}\left(R\tilde{Q}[A]; k \right) = \operatorname{Lie}_{\text{alg}}\left(\tilde{Q}[A]; k\right).
\]

In other words, $Y'(x) = R(x)\tilde{Q}(x)[A(x)]Y(x)$ is in reduced form.

\textbf{Proof of Theorem 3.3.} It follows from Lemma 3.4 that a reduction matrix can always be chosen of the form $P(x) = \begin{pmatrix}
\text{Id}_{n_1} & 0 \\
\text{Id}_{n_2}\operatorname{N}(x) & \text{Id}_{n_2}
\end{pmatrix} \in H(k)$, where $N(x) \in \mathcal{M}_{n_2,n_1}(k)$. By a straightforward computation, we find $\log(P(x)) = \begin{pmatrix}
0 & 0 \\
\operatorname{N}(x) & 0
\end{pmatrix} \in \mathfrak{h}(k)$. But with the same reasoning as in the proof of Lemma 3.1, we obtain that $\log(P(x)) \in \operatorname{Lie}_{\text{alg}}(A_{\text{sub}}; k)$. This concludes the proof of Theorem 3.3.

The following corollary will be crucial for the reduction procedure of 3.3.

\textbf{Corollary 3.5.} Assume that, for all gauge transformations of the form $P(x) \in \left\{ \text{Id}_n + B(x), B(x) \in \operatorname{Lie}_{\text{alg}}(A_{\text{sub}}; k) \right\}$, we have $\operatorname{Lie}(A; k) = \operatorname{Lie}(P[A]; k)$. Then, $Y'(x) = A(x)Y(x)$ is in reduced form.

\textbf{Proof.} Theorem 3.3 provides a $B(x) \in \operatorname{Lie}_{\text{alg}}(A_{\text{sub}}; k)$ and $P(x) = \text{Id}_n + B(x)$ such that the system $Y'(x) = P(x)[A(x)]Y(x)$ is in reduced form. In virtue of the hypothesis, $\operatorname{Lie}(A; k) = \operatorname{Lie}(P[A]; k)$. This implies that $\operatorname{Lie}_{\text{alg}}(A; k) = \mathfrak{g}(k)$, where $\mathfrak{g}$ is the Lie algebra of the differential Galois group $G$ of $Y'(x) = A(x)Y(x)$. This proves that $Y'(x) = A(x)Y(x)$ is in reduced form.
3.3. The Adjoint Action. We refer to [23] and [31] for the notations and definitions used in this subsection. In [32] we have proved the existence of a gauge transformation matrix $P(x) \in \{ \text{Id}_n + B(x), B(x) \in \text{Lie}_{\text{alg}}(A_{\text{sub}}; k) \}$, such that $Y'(x) = P(x)[A(x)]Y(x)$ is in reduced form. Let $B_1, \ldots, B_\sigma \in M_n(\mathbb{C})$ denote a basis of $\text{Lie}_{\text{alg}}(A_{\text{sub}})$.

**Proposition 3.6.** If $P(x) := \text{Id}_n + \sum_{i=1}^{\sigma} f_i(x)B_i$, with $f_i(x) \in k$ and $B_i \in \text{Lie}_{\text{alg}}(A_{\text{sub}})$, then

$$P(x)[A(x)] = A(x) + \sum_{i=1}^{\sigma} f_i(x)[B_i, A_{\text{diag}}(x)] - \sum_{i=1}^{\sigma} f'_i(x)B_i.$$ 

**Proof.** Due to the first point of Lemma 3.1, we have the equalities $P^{-1}(x) = \text{Id}_n - \sum_{i=1}^{\sigma} f_i(x)B_i$ and $P(x)A(x) = A(x) + \sum_{i=1}^{\sigma} f_i(x)B_iA_{\text{diag}}(x)$. As $A(x) = A_{\text{diag}}(x) + A_{\text{sub}}(x)$, we use Lemma 3.1 and find that

$$P(x)A(x)P^{-1}(x) = \left( A_{\text{diag}}(x) + A_{\text{sub}}(x) + \sum_{j=1}^{\sigma} f_j(x)B_jA_{\text{diag}}(x) \right) \left( \text{Id}_n - \sum_{k=1}^{\sigma} f_k(x)B_k \right)$$

$$= A(x) + \sum_{j=1}^{\sigma} f_j(x)B_jA_{\text{diag}}(x) - \sum_{k=1}^{\sigma} f_k(x)A_{\text{diag}}(x)B_k$$

$$= A(x) + \sum_{i=1}^{\sigma} f_i(x)[B_i, A_{\text{diag}}(x)].$$

Similarly, we have

$$P'(x)P^{-1}(x) = \left( \sum_{i=1}^{\sigma} f'_i(x)B_i \right) \left( \text{Id}_n - \sum_{j=1}^{\sigma} f_j(x)B_j \right) = \sum_{i=1}^{\sigma} f'_i(x)B_i.$$

This yields the desired result. \qed

We have seen in Lemma 3.1 that $\text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$ is an ideal in $h(k)$. In particular, for all $B(x) \in \text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$, the bracket $[B(x), A_{\text{diag}}(x)]$ is in $\text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$. This implies that the $k$-linear map $\Psi := [\bullet, A_{\text{diag}}(x)]$, which is the adjoint action of $\text{Lie}_{\text{alg}}(A_{\text{diag}}; k)$ on $\text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$, is well defined:

$$\Psi : \text{Lie}_{\text{alg}}(A_{\text{sub}}; k) \rightarrow \text{Lie}_{\text{alg}}(A_{\text{sub}}; k)$$

$$B(x) \mapsto [B(x), A_{\text{diag}}(x)].$$

The following lemma will be necessary in [34]. Note that the proof of the lemma gives a complete description of a finite set containing the eigenvalues of $\Psi$.

**Lemma 3.7.** The eigenvalues of the linear map $\Psi$ belong to $k$.

Furthermore, there exists a basis of constant matrices, such that the matrix of the linear map $\Psi$ in this basis is block-diagonal, with blocks that are upper-triangular matrices with only one eigenvalue.

**Proof.** Let $M_1, \ldots, M_\delta \in M_n(\mathbb{C})$ be a basis of $\text{Lie}_{\text{alg}}(A_{\text{diag}})$, which is abelian. We may write $A_{\text{diag}}(x) = \sum_{i=1}^{\delta} g_i(x)M_i$ with $g_i(x) \in k$. Let $\Psi_i := [\bullet, M_i]$ denote the adjoint action of $M_i$ on
Lie_{alg}(A_{sub}). As the matrices $M_i$ commute pairwise, the Jacobi identity on Lie brackets implies that the $\Psi_i$ also commute pairwise. The $\Psi_i$ have coefficients in the algebraically closed field $\mathbb{C}$ and commute pairwise, and therefore they are simultaneously triangularizable in a basis $(C_j)$ of Lie_{alg}(A_{sub}). By construction, the $C_j$ are constant matrices. Each $C_j$ lies in a characteristic space of $\Psi_i$ associated with an eigenvalue $\lambda_{i,j}$. We define $\lambda_j(x) := \sum_{i=1}^{\delta} g_i(x) \lambda_{i,j}$. As $\Psi = \sum_{i=1}^{\delta} g_i(\Psi_i)$, we see that the $\lambda_j(x) \in \mathbb{k}$ are the eigenvalues of $\Psi$ and that the matrix of $\Psi$ is triangular in the basis $(C_j)$ of Lie_{alg}(A_{sub};\mathbb{k})$.

**Remark 3.8.** One may refine this proof to predict the eigenvalues of $\Psi$. Let $\gamma_1(x), \ldots, \gamma_\omega(x) \in \mathbb{k}$ be the eigenvalues of $A_{\text{diag}}(x)$. The above reasoning shows the existence of $P_1 \in \text{GL}_n(\mathbb{C})$, such that $P_1 A_{\text{diag}}(x) P_1^{-1} = \begin{pmatrix} L_1(x) & \vdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & L_\omega(x) \end{pmatrix}$, where for $1 \leq i \leq \omega$, $L_i(x)$ is a matrix in coefficients in $\mathbb{k}$, with only one eigenvalue $\gamma_i(x)$.

In the proof of Lemma 2.7 we have proved the existence of a basis of constant matrices, such that the matrix of the linear map $\Psi$ in this basis is block-diagonal, with blocks that are upper-triangular matrices corresponding to convenient restriction of the linear maps $\Psi_{i,j} : X_{i,j} \to X_{i,j} L_i(x) - L_j(x) X_{i,j}$. For $1 \leq i, j \leq \omega$, the map $\Psi_{i,j}$ admits only one eigenvalue that is equal to $\gamma_i(x) - \gamma_j(x) \in \mathbb{k}$. Then, the eigenvalues of $\Psi$ are of the form $\{\gamma_i(x) - \gamma_j(x), 1 \leq i, j \leq \omega\}$. Now the diagonal blocks are symmetric powers of $A_{1,\text{red}}(x)$; the latter has an abelian associated Lie algebra and is triangular. It follows that the $\gamma_i(x)$ are linear combinations (with integer coefficients) of the eigenvalues of $A_{1,\text{red}}(x)$, so that the eigenvalues of $\Psi$ also are linear combinations (with integer coefficients) of the eigenvalues of $A_{1,\text{red}}(x)$.

### 3.4. Decreasing the Dimension of $\text{Lie}(A;\mathbb{k})$

We refer to Sections 3.1 and 3.2 for the notations and definitions used in this subsection. The aim of this section is to find a gauge transformation $P(x)$ such that $Y'(x) = P(x) [A(x)] Y(x)$ is in reduced form. Thanks to Corollary 3.5 it is sufficient to compute a gauge transformation $P(x) \in \{ \text{Id}_n + B(x), B(x) \in \text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k}) \}$ such that, for every gauge transformation $\tilde{Q}(x) \in \{ \text{Id}_n + B(x), B(x) \in \text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k}) \}$, we have $\text{Lie}(P[A]; \mathbb{k}) \subseteq \text{Lie} \left( \tilde{Q}[P[A]]; \mathbb{k} \right)$.

The $\mathbb{k}$-linear adjoint map $\Psi = [\bullet, A_{\text{diag}}] : \text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k}) \to \text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k})$ has its eigenvalues $\lambda_1(x), \ldots, \lambda_\kappa(x) \in \mathbb{k}$ (see Lemma 3.7) and its minimal polynomial has the form

$$\Pi_\Psi(X) = \prod_{i=1}^{\kappa} (X - \lambda_i(x))^m_i,$$

with $m_i \in \mathbb{N}^*$. For each eigenvalue $\lambda_i(x)$, we let $E_{\lambda_i} := \ker ((\Psi - \lambda_i(x) \text{Id}_\sigma)^{m_i})$ be the corresponding characteristic space. So we have the standard decomposition $\text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k}) = \bigoplus_{i=1}^{\kappa} E_{\lambda_i}$. Of course, the $E_{\lambda_i}$ are $\Psi$-invariant subspaces. Now $\text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k})$ is also a $\Psi$-invariant subspace of $\text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k})$. As the $E_{\lambda_i}$ have each a basis formed of constant matrices (Lemma 3.7), Proposition 3.6 implies that we thus have

$$\text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k}) = \bigoplus_{i=1}^{\kappa} \left( E_{\lambda_i} \cap \text{Lie}_{alg}(A_{\text{sub}}; \mathbb{k}) \right).$$

In the reduction process, we may (and will) hence perform a reduction on each $E_{\lambda_i}$ separately. So, without loss of generality, we now assume that $\Psi$ has one eigenvalue
We decompose $\lambda(x) \in k$ and $\Pi_\Psi(X) = (X - \lambda(x))^m$, for some $m \in \mathbb{N}^*$.

As above, we let $E_\lambda := \ker((\Psi - \lambda(x)\text{Id}_n)^m)$ and, for $i \in \{0, \ldots, m\}$, let $E_\lambda^{(i)} := \ker((\Psi - \lambda(x)\text{Id}_n)^i)$. We have the standard flag decomposition $E_\lambda = \bigoplus_{i=1}^m E_\lambda^{(i)}/E_\lambda^{(i-1)}$.

And, last, we recall that for $M(x) \in E_\lambda^{(i)}/E_\lambda^{(i-1)}$, we have

$$\Psi(M(x)) = \lambda(x)M(x) + \widetilde{M}(x), \quad \text{with} \quad \widetilde{M}(x) \in E_\lambda^{(i-1)}.$$

3.4.1. Reduction on One Level of a Characteristic Space. Let us first pretend that we know a basis $C_1, \ldots, C_t$ of $E_\lambda^{(m)}/E_\lambda^{(m-1)}$ (formed of constant matrices $C_i$, this is possible due to lemma 3.7) such that $C_{t+1}, \ldots, C_s$ form a basis of $g(k) \cap \left(E_\lambda^{(m)}/E_\lambda^{(m-1)}\right)$. This means that $C_1, \ldots, C_t$ could be “removed” by a gauge transformation.

We decompose $A(x)$ as $A(x) = \tilde{A}(x) + \sum_{i=1}^t a_i(x)C_i$, where $\tilde{A}(x) \in E_\lambda^{(m-1)}$. Our gauge transformation matrix is of the form $P(x) = \text{Id}_n + \sum_{i=1}^t f_i(x)C_i$ with $f_i(x) \in k$. As $\Psi(C_i) = \lambda(x)C_i + \tilde{C}_i$, with $\tilde{C}_i \in E_\lambda^{(m-1)}$, we apply Proposition 3.6 to obtain:

$$P[A] = \tilde{A}(x) + \sum_{i=1}^t f_i(x)\tilde{C}_i + \sum_{i=1}^t (a_i(x) + \lambda(x)f_i(x) - f_i'(x))C_i.$$

We see that, in order to achieve reduction in $E_\lambda^{(m)}/E_\lambda^{(m-1)}$, we should have

$$f_i'(x) = (\lambda(x)f_i(x) + a_i(x)) \quad \text{for all} \quad i \in \{1, \ldots, t\}.$$

In other words, the differential equation $y'(x) = \lambda(x)y(x) + a_i(x)$ should have a rational solution for each $i \in \{1, \ldots, t\}$.

In practice, we do not know the $C_i$ nor the $a_i(x)$ so we now show how to compute them. Let $B_1, \ldots, B_t$ denote a basis of $E_\lambda^{(m)}/E_\lambda^{(m-1)}$, formed of constant matrices. We will find candidates for the $C_i$ by computing which combinations of the $B_i$ may be “removed” from $A(x)$ by a gauge transformation as above. We decompose $A(x)$ as $A(x) = \tilde{A}(x) + \sum_{i=1}^t b_i(x)B_i$.

There exist (yet unknown) constants $c_{i,j}$ such that $B_i = \sum_{j=1}^t c_{i,j}C_j$, so that:

$$A(x) = \tilde{A}(x) + \sum_{i=1}^t b_i(x)\left(\sum_{j=1}^t c_{i,j}C_j\right) = \tilde{A}(x) + \sum_{j=1}^t \left(\sum_{i=1}^t c_{i,j}b_i(x)\right)C_j.$$

So, the calculation from the previous paragraph shows that there should exist $g_j(x) \in k$ such that, for $j \in \{1, \ldots, s\}$, $g_j'(x) = \lambda(x)g_j(x) + \sum_{i=1}^t c_{i,j}b_i(x)$. The way to find $s$, the $g_j(x)$ and the $c_{i,j}$ is given by Lemma 3.9 (which is proved here for convenience but is well known to specialists).
Lemma 3.9. Let $\lambda(x), b_1(x), \ldots, b_t(x)$ be elements of $k$. The set of tuples $(g(x), c_1, \ldots, c_t) \in k \times \mathcal{C}^t$ such that $g'(x) = \lambda(x)g(x) + \sum_{i=1}^{t} c_i b_i(x)$ is a $\mathcal{C}$-vector space. Moreover, one can effectively compute a basis of this vector space.

Proof. Let $L_{\mathcal{B}}$ be the linear differential operator of order $t$ whose solution space is spanned by $b_1(x), \ldots, b_t(x)$. Let $L := L_{\mathcal{B}} \cdot (\frac{d}{d x} - \lambda(x))$, where the product is the composition, i.e. the usual product in the non-commutative Ore ring $k[\frac{d}{d x}]$. One readily sees that a function $g(x) \in k$ satisfies $L(g(x)) = 0$ if and only if $L_{\mathcal{B}}(g'(x) - \lambda(x)g(x)) = 0$, i.e. if there exist constants $c_i \in \mathcal{C}$ such that $g'(x) - \lambda(x)g(x) = \sum_{i=1}^{t} c_i b_i(x)$. Hence, the set of tuples $(g(x), c_1, \ldots, c_t) \in k \times \mathcal{C}^t$ such that $g'(x) = \lambda(x)g(x) + \sum_{i=1}^{t} c_i b_i(x)$ is isomorphic with the set of rational solutions $g(x)$ of $L$. The latter is a vector space whose basis can be effectively computed, see [223,1].

Lemma 3.9 allows us to compute easily, see [223.1] a dimension $s \in \mathbb{N}$ and a basis 
$$\left((g_j(x), \mathcal{C}_{\bullet,j})\right)_{j=1,\ldots,s}$$
of elements in $k \times \mathcal{C}^t$ such that the equation $g'(x) = \lambda(x)g(x) + \sum_{i=1}^{t} c_{i,j} b_i(x)$ has a rational solution $y(x) = g_j(x)$. The unknown functions $a_i(x)$ that we were looking for are thus given by $a_i(x) = \sum_{i=1}^{t} c_{i,j} b_i(x)$.

Via the incomplete basis theorem, we construct a constant invertible matrix $Q \in \text{GL}_t(\mathcal{C})$ whose first $s$ columns are the $\mathcal{C}_{\bullet,j}$. We may view $Q$ as the base change matrix from the basis $(B_j)_{j=1}^{t}$ of $E^{(m)}_{\lambda}/E^{(m-1)}_{\lambda}$ to a new basis $(C_j)_{j=1}^{t}$ of $E^{(m)}_{\lambda}/E^{(m-1)}_{\lambda}$. Let $\gamma_{i,j}$ denote the entries of $Q^{-1}$.

Lemma 3.10. Let $s \in \mathbb{N}$, $(g_j(x))_{j=1,\ldots,s}$, and $(\gamma_{i,j})$ be computed as in the above paragraph. For $i \in \{1,\ldots,t\}$, let $f_i(x) := \sum_{j=1}^{s} \gamma_{i,j} g_j(x)$. Finally, let $P^{(m)}_{\lambda} := \text{Id}_n + \sum_{i=1}^{t} f_i(x) B_i$. Then $P^{(m)}_{\lambda}$ is a partial reduction matrix, in the sense that

$$\text{Lie}_{\text{alg}} \left(P^{(m)}_{\lambda}[A];k\right) \cap \left(E^{(m)}_{\lambda}/E^{(m-1)}_{\lambda}\right) = \mathfrak{g}(k) \cap \left(E^{(m)}_{\lambda}/E^{(m-1)}_{\lambda}\right).$$

Furthermore, for all $Q(x) := \text{Id}_n + \sum_{i=s+1}^{t} h_i(x) C_i$ with $h_{s+1}(x), \ldots, h_t(x) \in k$, we have

$$\text{Lie}(P^{(m)}_{\lambda}[A];k) = \text{Lie} \left(\tilde{Q}[P^{(m)}_{\lambda}[A]];k\right).$$

Proof. We apply the first point of Proposition 2.1 (because $G$ is connected, see the proof of Lemma 3.3) to deduce that $\mathfrak{g}(k) \subseteq \text{Lie}_{\text{alg}} \left(P^{(m)}_{\lambda}[A];k\right)$. Then,

$$\mathfrak{g}(k) \cap \left(E^{(m)}_{\lambda}/E^{(m-1)}_{\lambda}\right) \subseteq \text{Lie}_{\text{alg}} \left(P^{(m)}_{\lambda}[A];k\right) \cap \left(E^{(m)}_{\lambda}/E^{(m-1)}_{\lambda}\right).$$
We want to prove the equality. By construction, $C_1, \ldots, C_s$ vanish in the construction of $P^{(m)}_\lambda [A]$ so that $C_{s+1}, \ldots, C_t$ now form a basis of Liealg $\left( P^{(m)}_\lambda [A]; k \right) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right)$.

Due to Theorem 3.3, there exists $R(x) = \text{Id}_n + \sum_{i=s+1}^{t} h_i(x)C_i + R(x)$, with $h_i(x) \in k$,

$$R(x) \in E^{(m-1)}_\lambda,$$

such that

$$g(k) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right) = \text{Liealg} \left( \tilde{R}[P^{(m)}_\lambda [A]]; k \right) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right).$$

But by construction, we have the inclusion

$$\text{Lie}(P^{(m)}_\lambda [A]; k) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right) \subseteq \text{Lie} \left( \tilde{R}[P^{(m)}_\lambda [A]]; k \right) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right).$$

Combining (3.3), (3.6) and (3.7) proves (3.4).

Let $\tilde{Q}(x) := \text{Id}_n + \sum_{i=s+1}^{t} h_i(x)C_i$ with $h_{s+1}(x), \ldots, h_t(x) \in k$. By construction, we have

$$\text{Lie}(P^{(m)}_\lambda [A]; k) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right) = \text{Lie} \left( \tilde{Q}[P^{(m)}_\lambda [A]]; k \right) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right).$$

Let $\tilde{C}_j := \Psi(C_j) - \lambda(x)C_j$. We use (3.3) and the fact that $\Psi$ is $k$-linear plus Proposition 3.6 to deduce the existence of $A(x) \in \text{Lie}(P^{(m)}_\lambda [A]; k) \cap \left( E^{(m)}_\lambda / E^{(m-1)}_\lambda \right)$ such that

$$P^{(m)}_\lambda(x)[A(x)] = \tilde{Q}(x)[P^{(m)}_\lambda(x)[A(x)]] = A(x) + \sum_{i=s+1}^{t} h_i(x) \tilde{C}_i.$$

Let $j \in \{s+1, \ldots, t\}$. We know that $C_j \in \text{Lie}(P^{(m)}_\lambda [A]; k)$. By definition, the matrix $\tilde{C}_j = \Psi(C_j) - \lambda(x)C_j$ belongs to $\text{Lie}(P^{(m)}_\lambda [A]; k) \cap E^{(m-1)}_\lambda$. Due to (3.8), it also belongs to $\text{Lie} \left( \tilde{Q}[P^{(m)}_\lambda [A]]; k \right) \cap E^{(m-1)}_\lambda$. Then, $\sum_{i=s+1}^{t} h_i(x) \tilde{C}_j$ belongs to $\text{Lie}(P^{(m)}_\lambda [A]; k) \cap E^{(m-1)}_\lambda$

and $\text{Lie} \left( \tilde{Q}[P^{(m)}_\lambda [A]]; k \right) \cap E^{(m-1)}_\lambda$. We combine this fact and (3.9) to deduce

$$\text{Lie}(P^{(m)}_\lambda [A]; k) \cap E^{(m-1)}_\lambda = \text{Lie} \left( \tilde{Q}[P^{(m)}_\lambda [A]]; k \right) \cap E^{(m-1)}_\lambda.$$  

Combining (3.8) and this equality, we find the result.

3.4.2. The Full Reduction Procedure. The reduction procedure now is easy to establish by iterating the above process. By assumption, all variational equations of lower order are in reduced form and have an abelian associated Lie algebra.

Choose an eigenvalue $\lambda(x) \in \text{Spec}(\Psi)$ of the adjoint map $\Psi = [\cdot, A_{\text{diag}}]$. Let $E_\lambda := E^{(m)}_\lambda$ be the corresponding characteristic space. Let $l := m$.

Compute a constant basis $(B_i)_{i=1..t}$ of $E^{(l)}_\lambda / E^{(l-1)}_\lambda$ and compute the partial reduction matrix $P^{(l)}_\lambda := \text{Id}_n + \sum_{i=1}^{t} f_i(x)B_i$ as in Lemma 3.10. Perform the transformation $A(x) := P^{(l)}_\lambda(x)[A(x)]$, let $l := l - 1$ and iterate this paragraph until $l = 0$. 

When all these successive steps are performed, let \( P_{\lambda}(x) := \prod_{l=1}^{m} P_{\lambda}^{(l)}(x) \). Note that, by construction, the matrices \( P_{\lambda}^{(l)}(x) \) commute pairwise so the order does not matter in the latter product.

Now perform this for all eigenvalues \( \lambda(x) \in \text{Spec}(\Psi) \). The resulting matrix is a reduced form.

**Theorem 3.11.** Using the algorithm and notations of the above paragraph, let

\[
P(x) := \prod_{\lambda(x) \in \text{Spec}(\Psi)} P_{\lambda}(x) \quad \text{and} \quad A_{p,\text{red}}(x) := P(x)[A(x)].
\]

Then the system \( Y'(x) = A_{p,\text{red}}(x)Y(x) \) is in reduced form and \( P(x) \) is the corresponding reduction matrix.

**Proof.** Define \( \overline{A_{\text{sub}}}(x) \) as the off-diagonal part of \( A_{p,\text{red}}(x) \) as in the rest of this section. Pick any matrix \( H(x) \in \text{Lie}_\text{alg} \left( \overline{A_{\text{sub}}}; k \right) \cap \left( P_{\lambda}^{(l)}/P_{\lambda}^{(l-1)} \right) \) for some \( \lambda(x) \in \text{Spec}(\Psi) \), for some integer \( l \). Let \( \tilde{Q}(x) := \text{Id}_n + H(x) \). Then, Lemma 3.10 implies that we have the equality \( \text{Lie}(A_{p,\text{red}}; k) = \text{Lie} \left( \tilde{Q}[A_{p,\text{red}}]; k \right) \). Now, Lemmas 3.1 and 3.2 show that any matrix in \( \left\{ \text{Id}_n + B(x), B(x) \in \text{Lie}_\text{alg} \left( \overline{A_{\text{sub}}}; k \right) \right\} \) is a product of matrices \( \text{Id}_n + H(x) \) of the above form. It follows that, for every gauge transformation \( \tilde{Q}(x) \) in the set \( \left\{ \text{Id}_n + B(x), B(x) \in \text{Lie}_\text{alg} \left( \overline{A_{\text{sub}}}; k \right) \right\} \), we have \( \text{Lie}(A_{p,\text{red}}; k) = \text{Lie} \left( \tilde{Q}[A_{p,\text{red}}]; k \right) \). So, Corollary 3.5 shows that the system \( Y'(x) = A_{p,\text{red}}(x)Y(x) \) is in reduced form and \( P(x) \) is the corresponding reduction matrix. \( \square \)

4. **Back to the Morales-Ramis-Simó Integrability Criterion**

4.1. **Reducing the First Variational Equation.** Initially we assumed that the first variational equation had been put into reduced form and had an abelian associated Lie algebra. However, the procedure described in this paper can be also used to put the first variational equation into reduced form, i.e. to apply effectively the original Morales-Ramis integrability criterion. This allows us to recover the reduction method established by two of the authors in [AMW12].

First, factor the first variational equation, i.e. compute an equivalent lower block-triangular form differential system. (see e.g. [PS03]). Then, apply a reduction procedure to the irreducible blocks on the diagonal (for example the one of Aparicio-Compoint-Weil from [AMCW13]). This will put these blocks in diagonal form (maybe after an algebraic extension); otherwise we have an obstruction to integrability (Boucher-Weil criterion, see [BW03 MRR10]). If the blocks have dimension 1 or 2, then a faster method using a variant of the Kovacic algorithm is given in [AMW12].

Once this is done, the method of this paper allows us to reduce the lower triangular blocks, thus putting the first variational equation into reduced form.

4.2. **The Effective Morales-Ramis-Simó Integrability Criterion.** The Morales-Ramis-Simó integrability criterion states that if one of the variational equations of a Hamiltonian system has a differential Galois group whose Lie algebra is not abelian, then it is
not (meromorphically) Liouville integrable. For \( p \in \mathbb{N}^* \), let \( Y'(x) = A_p(x)Y(x) \) be the variational equation of order \( p \), let \( G_p \) be the differential Galois group of \( Y'(x) = A_p(x)Y(x) \) and let \( g_p \) be the Lie algebra of \( G_p \).

As we have seen in \( \S 4.2 \), we may use the procedure of \( \S 3 \) to put the first variational equation \( Y'(x) = A_1(x)Y(x) \) in reduced form. If \( g_1 \) is not abelian, which can be checked easily, then the original Morales-Ramis integrability criterion fails. Let \( p \geq 2 \) and assume that, for all \( m \in \{1, \ldots, p - 1\} \), we know a gauge transformation matrix \( P_m(x) \) such that \( P_m(x)[A_m(x)] \) is in reduced form, i.e. \( \text{Lie}_\text{alg}(P_m[A_m]) = g_m \). We further assume that each \( g_m \) is abelian. Then, see \( \S 2.2 \), the \( p^{th} \) variational equation is of the form

\[
Y'(x) = A_p(x)Y(x), \quad \text{where } A_p(x) := \begin{pmatrix} \frac{\text{sym}^p(A_1(x))}{S_p(x)} & 0 \\ \frac{\text{sym}^p(P_1(x))}{P_p(x)} & 0 \\ \end{pmatrix}
\]

and the matrix \( S_p(x) \) has entries in \( k \). Let \( Q(x) := \begin{pmatrix} \frac{\text{sym}^p(P_1(x))}{P_p(x)} & 0 \\ 0 & \frac{\text{sym}^p(A_1,\text{red}(x))}{A_p,\text{red}(x)} \\ \end{pmatrix} \) and consider (see \( \S 2.5 \))

\[
A(x) := Q(x)[A_p(x)] = \begin{pmatrix} \frac{\text{sym}^p(A_1,\text{red}(x))}{S(x)} & 0 \\ \frac{\text{sym}^p(P_1(x))}{P_p(x)} & \frac{\text{sym}^p(A_1,\text{red}(x))}{A_p,\text{red}(x)} \\ \end{pmatrix}.
\]

Let \( P(x) \) be the gauge transformation that we have computed in \( \S 3.4 \). Then,

\[
A_p,\text{red}(x) := P(x)[A(x)] = P(x)[Q(x)[A_p(x)]]
\]

is in reduced form. If \( g_p \) is not abelian, which now can be easily checked, the Morales-Ramis-Simó integrability criterion fails. If \( g_p \) is abelian, we may iterate the same procedure in order to put \( Y'(x) = A_{p+1}(x)Y(x) \) in reduced form.

To summarize, for any \( p \geq 2 \), we are able to put the successive variational equations

\[
Y'(x) = A_1(x)Y(x), \ldots, Y'(x) = A_p(x)Y(x)
\]

in reduced form or prove that one of the \( g_i \) is not abelian.

In view of the applications of this reduction procedure to the Morales-Ramis-Simó integrability criterion, we have the following shortcut. We refer to \( \S 2 \) and \( \S 3 \) for the notations used in this subsection. The Morales-Ramis-Simó integrability criterion implies that, if the Hamiltonian system is integrable, once our reduced form from Theorem \( 3.11 \) is computed, \( g_p \) should be abelian for all \( p \in \mathbb{N}^* \). With Lemma \( 3.7 \) we find that this is equivalent to saying that the resulting adjoint map \( \Psi_{\text{red}} = [\bullet, A_{\text{diag}}] \) should be the zero map (because \( \text{Lie}_\text{alg}(A_{\text{sub}}) \) is always abelian and \( \text{Lie}_\text{alg}(A_{\text{diag}}) \) is assumed to be abelian).

So, when performing the reduction, any characteristic space \( E_\lambda \) corresponding to a non-zero eigenvalue \( \lambda(x) \in \text{Spec}(\Psi) \) must vanish. Also, for \( \lambda = 0 \), all \( E_0^{(l)} \) (for \( l \geq 2 \)) must vanish too. As a consequence, if one is only interested in finding an obstruction to integrability but not necessarily a reduced form, the reduction step in \( \S 4.4 \) can be significantly simplified.

Indeed (we use the notations from \( \S 4.1 \)), instead of the equation with parametrized right-hand side in Lemma \( 3.9 \) it is enough to look for a rational solution \( g_i(x) \) to each equation \( y'(x) = \lambda(x)g(x) + b_i(x) \). If any of these equations does not have a rational solution, then the adjoint map \( \Psi_{\text{red}} \) of the reduced form will still have the non-zero eigenvalue \( \lambda(x) \), hence yielding an obstruction to abelianity of the associated Lie algebra.

Otherwise, the partial reduction matrix of Lemma \( 3.10 \) is easier to compute: just let
\[ P_\lambda^{(m)}(x) := \text{Id}_n + \sum_{i=1}^{t} g_i(x)B_i, \] compute \( P_\lambda^{(m)}(x)[A(x)] \), compute a basis \( (B_i) \) of the new space \( E_\lambda^{(m-1)} \) and iterate this reduction as in [3.4.1]. Do this for all non-zero eigenvalues of \( \Psi \). For the zero eigenvalue, proceed similarly for the \( E_0^{(l)} \) (for all \( l > 2 \)). Note that since \( \lambda = 0 \), the problem is slightly easier. Indeed, using the notation from [3.4.1], we only have to check whether every \( b_i(x) \) admits a primitive \( g_i(x) \in k \). If any of the \( b_i(x) \) does not admit a primitive in \( k \), we obtain an obstruction to abelianity. Otherwise, the partial reduction matrix will be \( P_0^{(l)}(x) := \text{Id}_n + \sum_{i=1}^{t} g_i(x)B_i \). If at this stage the process has not stopped, the partially reduced matrix has an associated Lie algebra which is abelian so the application of the Morales-Ramis-Simó integrability criterion now makes it necessary to go to the next higher variational equation.

We may even iterate the process to the next variational equation without finishing the reduction: the only assumption that was used in our algorithmic construction was that the Lie algebra associated to the previous variational equation was abelian. However, this is not very satisfying and one should, at this last step, compute the reduced form by applying Lemma 3.9 until the final case \( \lambda = 0 \) and \( m = 1 \). Since \( \lambda = 0 \), the computations here are slightly easier.

5. An Example

Consider the Hamiltonian with potential given by \( H := \frac{1}{2}p_1^2 + \frac{1}{2}p_2^2 + V \), where the potential is given by
\[
V = \frac{q_2}{q_3} \left( 9q_1^2 + q_2^2 \right).
\]
This potential appears at the end of [CDMP10] where the authors present it as a case where their necessary conditions are all satisfied so that one could guess that the system might be integrable, but it is left as an open case. The corresponding Hamiltonian system is
\[
(X_H) : \begin{cases} 
\dot{q}_1 &= p_1 \\
\dot{q}_2 &= p_2 \\
\dot{p}_1 &= 3q_2 (3q_1^2 + q_2^2) \\
\dot{p}_2 &= -3 \frac{3q_1^4 + q_2^2}{q_1^2 + q_2^2} 
\end{cases}
\]
Using the method of Darboux points and homothetic solutions (see [CDMP10] or the papers by the same authors or the papers by Combot in the references), we find a (rather obvious) pencil of particular solutions
\[
q_1 = \lambda x, \quad q_2 = \sqrt{-3}q_1 = \sqrt{-3} \lambda x, \quad p_1 = \dot{q}_1 = \lambda, \quad p_2 = \sqrt{-3}p_1 = \sqrt{-3} \lambda.
\]
To simplify the expression of later results, we choose \( \lambda = 4 i^{3/4} \sqrt{\frac{i}{m^2 - 1}} \); the pencil now depends on a free parameter \( m \) and our particular solutions are:
\[
q_1 = 4 i^{3/4} \sqrt{\frac{i}{m^2 - 1}} x, \quad q_2 = 12 \cdot 3^{1/4} \sqrt{\frac{i}{m^2 - 1}} x, \quad p_1 = 4 i^{3/4} \sqrt{\frac{i}{m^2 - 1}}, \quad p_2 = 12 \cdot 3^{1/4} \sqrt{\frac{i}{m^2 - 1}}.
\]
5.1. First Variational Equation. The first variational equation has matrix $A_1$ with

$$A_1 = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\frac{3}{8} m^2 - 1 & -i \sqrt{3} (m^2 - 1) & 0 & 0 \\
-i \sqrt{3} (m^2 - 1) & \frac{3}{8} m^2 - 1 & 0 & 0
\end{pmatrix}.$$ 

Following [4,1] we find a reduction matrix for this first variational equation:

$$P_1 = \begin{pmatrix}
x & 1 & i \sqrt{3} & 1 \\
-i x \sqrt{3} & -i \sqrt{3} & 1 & -i/3 \sqrt{3} \\
1 & 0 & \frac{i}{2} \sqrt{3} (m-1) & -1/2 \frac{m-1}{x} \\
-i \sqrt{3} & 0 & 1/2 \frac{m+1}{x} & i/6 \sqrt{3} (m-1)
\end{pmatrix}.$$  

So, the reduced form of the first variational equation is

$$A_{1,\text{red}} = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & \frac{1}{2} \frac{m+1}{x} & 0 & 0 \\
0 & 0 & 0 & -\frac{1}{2} \frac{m-1}{x}
\end{pmatrix}.$$ 

The associated Lie algebra is one dimensional (and abelian). We hence turn to the second variational equation.

5.2. Second Variational Equation. The matrix of the second variational equation is

$$A_2(x) = \left( \frac{\text{sym}^2 (A_1(x))}{S_2(x)} \middle| 0 \right).$$ 

We start with the partial reduction matrix

$$Q_{2,1}(x) = \left( \frac{\text{Sym}^2 (P_1(x))}{0} \middle| P_1(x) \right),$$

to obtain

$$A(x) := Q_{2,1}(x) [A_2(x)] = \left( \frac{\text{sym}^2 (A_{1,\text{red}}(x))}{S_{2,1}(x)} \middle| 0 \right).$$

where

$$S_{2,1}(x) = c_2 \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{x^3} & \frac{1}{x^2} & \frac{1}{x} \\
0 & 0 & 0 & 0 & 0 & \frac{1}{mz^2} & \frac{1}{zm^2} & -\frac{1}{x} & -\frac{1}{x^2} & -1 \\
0 & \frac{1}{xm} & \frac{1}{m} & 0 & \frac{1}{mz^2} & \frac{1}{zm^2} & \frac{10/3 i \sqrt{3}}{x} & \frac{10/3 i \sqrt{3}}{zm^2} & \frac{10/3 i \sqrt{3}}{m} \\
0 & 0 & \frac{1}{zm^2} & -\frac{1}{xm} & 0 & -\frac{1}{mz^2} & -\frac{10/3 i \sqrt{3}}{x} & -\frac{10/3 i \sqrt{3}}{zm^2} & -\frac{10/3 i \sqrt{3}}{m}
\end{pmatrix}$$

with $c_2 = \frac{1}{48} (1 + i) (m^2 - 1)^{3/2} \sqrt{2} \cdot 3^{1/3}$.

The off-diagonal Lie algebra $h_{\text{sub}}$ is generated by four matrices and calculation shows that it has dimension 10. The matrix $\Psi$ of the adjoint action $[A_{\text{diag}}, \bullet]$ on $h_{\text{sub}}$ has eigenvalues
we perform the first partial reduction on the diagonal to obtain

$$A_{2, \text{red}}(x) \left( \begin{array}{c|c} \text{sym}^2(A_{1, \text{red}}(x)) & 0 \\ \hline S_{2, \text{red}}(x) & A_{1, \text{red}}(x) \end{array} \right)$$

where

$$S_{2, \text{red}}(x) = c_2 \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -\frac{1}{x} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$ We remark that Lie($A_{2, \text{red}}$) is one-dimensional (because $x A_{2, \text{red}}$ is a constant matrix) whereas its algebraic envelope Lie$_{\text{alg}}(A_{2, \text{red}})$ is two dimensional. This follows from the fact that an algebraic Lie algebra contains both the semi-simple and nilpotent part of each of its elements. This can also be seen by solving the reduced system. This is now very easy and the Picard-Vessiot extension is $k(x, \frac{\ln(x)}{x^{m+1}})$, which has transcendence degree two over $k$. A simple calculation (or a look at the Picard-Vessiot extension) shows that Lie($A_{2, \text{red}}$) is again abelian so we may proceed to the third variational equation.

5.3. **Third Variational Equation.** We do what we did for the second variational equation; we perform the first partial reduction on the diagonal to obtain

$$A(x) := Q_{3, 1}(x)[A_3(x)] = \left( \begin{array}{c|c} \text{sym}^3(A_{1, \text{red}}(x)) & 0 \\ \hline S_{3, 1}(x) & A_{3, \text{red}}(x) \end{array} \right).$$

The off-diagonal Lie algebra $\mathfrak{h}_{\text{sub}}$ now has dimension 33. The matrix $\Psi$ of the adjoint action $[A_{\text{diag}}, \bullet]$ on $\mathfrak{h}_{\text{sub}}$ is no longer diagonalizable. Letting again $f_2 := \frac{m+1}{2x}$, the minimal polynomial $\Pi_\Psi(X)$ of $\Psi$ is

$$X^2 (X - f_2)^2 (X + f_2)^2 (X - 2f_2)^2 (X + 2f_2)^2 (X - 3f_2) (X + 3f_2) (X - 4f_2) (X + 4f_2).$$

Our reduction procedure turns $S_{3, 1}(x)$ into $S_{3, \text{red}}(x) := \frac{x}{m} M_3$, where $M_3$ is the matrix

$$\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$ The associated Lie algebra Lie$_{\text{alg}}(A_{3, \text{red}})$ is still two-dimensional and is still abelian. Actually, the reduced system is easily solved and its Picard-Vessiot extension is the same as that of $VE_2$ so they still have the same (abelian) differential Galois group.
6. Conclusion

The reduction procedure established in this paper gives an effective version of the Morales-Ramis-Simó criterion in the sense that it allows us to effectively test whether an \( p \)-th variational equation has an abelian Lie algebra. However, when the first \( p - 1 \) variational equations have an abelian Lie algebra but the \( p \)-th does not, there is no known way to measure \textit{a priori} which \( p \) would be needed. So, one may apply the reduction iteratively to higher and higher order but there is no criterion for determining when to stop. Also, when all variational equations have an abelian Lie algebra, the system could still be non-integrable (but one would see this on the variational equations along another particular solution).

This reduction procedure will also allow further study of how the dimensions of the Galois groups of the successive variational equations evolve, both in integrable and non-integrable situations.

The reduced form may also be combined with the methods of \cite{AMBSW11, Sim14b} for finding Taylor expansions of first integrals. Once the system is in reduced form, the results of \cite{AMCW13} show that the Taylor expansions of a first integral, along the particular solution \( \Gamma \), have constant coefficients. So, once the system is in reduced form, the (eventual) first integrals are easily found. In that sense, our reduced forms appear as pre-normal forms along \( \Gamma \). Pushing the reduction further to develop a normal form theory would be a natural development.

The concepts of variational equations are \textit{mutatis mutandis} the same for general (non-Hamiltonian) dynamical systems (see e.g. \cite{Cas09} or \cite{CW15}, where several notions of variational equations are compared). The notion of Liouville integrability may be generalized to these contexts by Bogoyavlenskij integrability: the notion of involution of first integrals is replaced by the (equivalent) notion of commuting vector fields, see \cite{AZ10, BC05, Bog96, CB97}. The Morales-Ramis-Simó theory is generalized in \cite{AZ10, Cas09} to any kind of ordinary differential systems. The reader may remark that, in this paper, we essentially never use the symplectic structure of the Hamiltonian system from which we started. Hence, the reduction methods that we developed in the (symplectic) Morales-Ramis-Simó context extends naturally to any Bogoyavlenskij integrable differential system.

Our reduction procedure is interesting in its own right because it applies to other kinds of "solvable" situations that can be found in the context of differential Galois theories. Indeed, consider a differential system of the form \( Y' = A(x)Y \) where \( A(x) \) has the form

\[
A(x) = \begin{pmatrix}
\frac{A_1(x)}{S(x)} & 0 \\
S(x) & A_2(x)
\end{pmatrix}.
\]

Assume that the block-diagonal part \( \begin{pmatrix}
\frac{A_1(x)}{0} & 0 \\
0 & A_2(x)
\end{pmatrix} \) is in reduced form and has an abelian associated Lie algebra. Our reduction procedure readily extends to this (slightly more general) situation and puts the system into reduced form. In particular, it may be viewed as a way to pre-simplify the solutions.
Last, we mention the case of diagonals with a non-abelian Lie algebra. In [CW15], Casale and Weil develop a similar reduction technique to a family of systems in the above form but where \( \begin{pmatrix} A_1(x) & 0 \\ 0 & A_2(x) \end{pmatrix} \) has a non-abelian Lie algebra. Mixing these ideas and the ones developed in this work may provide a way toward a reduction method for general reducible linear differential systems.
