Abstract

We study the Stochastic Shortest Path (SSP) problem in which an agent has to reach a goal state in minimum total expected cost. In the learning formulation of the problem, the agent has no prior knowledge about the costs and dynamics of the model. She repeatedly interacts with the model for $K$ episodes, and has to minimize her regret. In this work we show that the minimax regret for this setting is \( \tilde{O}(\sqrt{(B^2_s + B_s)|S||A|K}) \) where \( B_s \) is a bound on the expected cost of the optimal policy from any state, \( S \) is the state space, and \( A \) is the action space. This matches the \( \Omega(\sqrt{B^2_s|S||A|K}) \) lower bound of Rosenberg et al. [2020] for \( B_s \geq 1 \), and improves their regret bound by a factor of \( \sqrt{|S|} \). For \( B_s < 1 \) we prove a matching lower bound of \( \Omega(\sqrt{B_s|S||A|K}) \). Our algorithm is based on a novel reduction from SSP to finite-horizon MDPs. To that end, we provide an algorithm for the finite-horizon setting whose leading term in the regret depends polynomially on the expected cost of the optimal policy and only logarithmically on the horizon.

1 Introduction

We study the stochastic shortest path (SSP) problem in which an agent aims to reach a predefined goal state while minimizing her total expected cost. This is one of the most basic models of reinforcement learning (RL) that includes both finite-horizon and discounted Markov Decision Processes (MDPs) as special cases. In addition, SSP captures a wide variety of realistic scenarios such as car navigation, game playing and drone flying.

We study an online version of SSP in which both the immediate costs and transition distributions of the model are initially unknown to the agent. The agent interacts with the model for $K$ episodes, in each of which she attempts to reach the goal state with minimal cumulative cost. A main challenge in the online model is found when instantaneous costs are small. For example, any learning algorithm that attempts to myopically minimize the accumulated costs might get caught in a cycle with zero cost and never reach the goal state. Nonetheless, even if the costs are not zero, only very small, the agent must be able to trade off the need to minimize costs with that of reaching the goal quickly.

The online setting was originally suggested by [Tarbouriech et al., 2020] who gave an algorithm with \( \tilde{O}(K^{23}) \) regret guarantee. In a follow-up work, Rosenberg et al. [2020] improved the previous bound to \( \tilde{O}(B_s|S||A||K^{1/3}) \), where \( S \) is the state space, \( A \) is the action space, and \( B_s \) is an upper bound on the total expected cost of the optimal policy when initialized at any state. Rosenberg et al. [2020] also provide a lower bound of \( \Omega(\sqrt{B_s|S||A||K}) \) – leaving a gap of \( \sqrt{|S|} \) between the upper and lower bounds. In this work, unlike the previously mentioned works that assume the cost function is deterministic.
and known, we consider the case where the costs are i.i.d. and initially unknown. We prove upper and lower bounds for this case, proving that the optimal regret is of order $\Theta(\sqrt{(B^2 + B^*_s)}|S||A||K)}$.

The idea of reducing SSP to finite-horizon was previously used by Chen et al. [2020], Chen and Luo [2020]. The algorithms of both Tarbouriech et al. [2020], Rosenberg et al. [2020] were based on a direct application of the “Optimism in the Face of Uncertainty” principle to the SSP model, following the ideas behind the UCRL2 algorithm [Jaksch et al., 2010] for average-reward MDPs. In this work we take a different approach. We propose a novel black-box reduction to finite-horizon MDPs, showing that the SSP problem is not harder than the finite-horizon setting assuming prior knowledge on the expected time it takes for the optimal policy to reach the goal state. While the reduction itself is simple, the analysis is highly nontrivial as one has to show that the goal state is indeed reached in every episode without incurring excessive costs in the process.

The idea of reducing SSP to finite-horizon was previously used by Chen et al. [2020], Chen and Luo [2021] for SSP with adversarially changing costs. However, they run one finite-horizon episode in every SSP episode and then simply try to reach the goal as fast as possible, while we restart a new finite-horizon episode every $H$ steps. This modification is what enables us to obtain the optimal and improved dependence in the number of states.

In addition, we provide a new algorithm for regret minimization in finite-horizon MDPs called ULCVI. We show that (for large enough number of episodes) its regret depends polynomially on the expected cost of the optimal policy $B_*$, and only logarithmically on the horizon length $H$. This implies that the correct measure for the regret is the expected cost of the optimal policy and not the length of the horizon. We note that regret with logarithmic dependence in the horizon $H$ was also obtained by Zhang et al. [2020], yet they make a much stronger assumption: that the cumulative cost of every trajectory is bounded by 1. In contrast, we only assume that the expected cost of the optimal policy is bounded by some constant $B_*$, while other policies may suffer a cost of $H$.

Our reduction, when combined with our finite-horizon algorithm ULCVI, guarantees SSP regret of $O(\sqrt{(B^2 + B^*_s)}|S||A||K)}$. This matches the lower bound of Rosenberg et al. [2020] for $B_* \geq 1$ up to logarithmic factors. However, their lower bound does not hold for $B_* < 1$ suggesting that this is not the correct rate in this case. Indeed, we prove a tighter lower bound of $\Omega(\sqrt{B^*_s}|S||A||K)}$ for $B_* < 1$, showing that our regret guarantees are minimax optimal in all cases.

As a final remark we note that, following our work, Tarbouriech et al. [2021] were able to obtain a comparable regret bound for SSP without prior knowledge of the optimal policy’s expected time to reach the goal state.

1.1 Additional related work

Planning for stochastic shortest path. Early work by Bertsekas and Tsitsiklis [1991] studied planning in SSPs, i.e., computing the optimal strategy efficiently when parameters are known. Under certain assumptions, they established that the optimal strategy is a deterministic stationary policy and can be computed efficiently using standard planning algorithms, e.g., Value Iteration and LP.

Adversarial stochastic shortest path. Rosenberg and Mansour [2020] presented stochastic shortest path with adversarially changing costs. Their regret bounds were improved by Chen et al. [2020], Chen and Luo [2021] using a reduction to online loop-free SSP (see next paragraph). As mentioned before, our reduction is different and therefore able to remove the extra $\sqrt{N}$ factor in the regret.

Regret minimization in MDPs. There is a vast literature on regret minimization in RL that mostly builds on the optimism principle. Most literature focuses on the tabular setting Jaksch et al., 2010, Azar et al., 2017, Jin et al., 2018, Fruit et al., 2018, Zanette and Brunskill, 2019, Efroni et al., 2019, Simchowitz and Jamieson, 2019, but recently it was extended to function approximation under various assumptions Yang and Wang, 2019, Jin et al., 2020b, Zanette et al., 2020, b.

Online loop-free SSP. A different line of work considers finite-horizon MDPs with adversarially changing costs Neu et al., 2010, 2012, Zimin and Neu, 2013, Rosenberg and Mansour, 2019b, d, Jin et al., 2020a, Cai et al., 2020, Shani et al., 2020, Lancewicki et al., 2020, Lee et al., 2020, Jin and Luo, 2020. They refer to finite-horizon adversarial MDPs as online loop-free SSP. This is not to be confused with our setting in which the interaction between the agent and the environment ends only when (and if) the goal state is reached, and not after a fixed number of steps $H$. See
We denote the optimal proper policy by $\pi^\star$. Any policy $\pi$ is improper. We additionally denote by $\pi$ any proper policy. An instance of the SSP problem is defined by an MDP $M = (S, A, P, c, s_{\text{init}}, g)$ where $S$ is a finite state space and $A$ is a finite action space. The agent begins at an initial state $s_{\text{init}} \in S$, and ends her interaction with $M$ by arriving at the goal state $g$ (where $g \notin S$). Whenever she plays action $a$ in state $s$, she pays a cost $C \in [0, 1]$ drawn i.i.d. from a distribution with expectation $c(s, a) \in [0, 1]$ and the next state $s' \in S \cup \{g\}$ is chosen with probability $P(s' \mid s, a)$. Note that the transition function $P$ satisfies $\sum_{s' \in S \cup \{g\}} P(s' \mid s, a) = 1$ for every $(s, a) \in S \times A$.

**Proper policies.** A stationary and deterministic policy $\pi : S \mapsto A$ is a mapping that selects action $\pi(s)$ whenever the agent is at state $s$. A policy $\pi$ is called proper if playing according to $\pi$ ensures that the goal state is reached with probability 1 when starting from any state (otherwise it is improper). In SSP, the agent has two goals: (a) reach the goal state; (b) minimize the total expected cost. To facilitate the first goal, we make the basic assumption that there exists at least one proper policy. In particular, the goal state is reachable from every state, which is clearly a necessary assumption.

Any policy $\pi$ induces a cost-to-go function $J^\pi : S \mapsto [0, \infty]$. The cost-to-go at state $s$ is defined by $J^\pi(s) = \lim_{T \to \infty} \mathbb{E}_{\pi}[\sum_{t=1}^{T} c(s_t, a_t) \mid s_{\text{init}} = s]$, where the expectation is taken w.r.t the random sequence of states generated by playing according to $\pi$ when the initial state is $s$. For a proper policy $\pi$, it follows that $J^\pi(s)$ is finite for all $s \in S$. However, note that $J^\pi(s)$ may be finite even if $\pi$ is improper. We additionally denote by $T^\pi(s)$ the expected time it takes for $\pi$ to reach $g$ starting at state $s$; in particular, if $\pi$ is proper then $T^\pi(s)$ is finite for all $s \in S$, and if $\pi$ is improper there must exist some state $s$ such that $T^\pi(s) = \infty$.

**Learning formulation.** Here, the agent does not have any prior knowledge of the cost function $c$ or transition function $P$. She interacts with the model in episodes: each episode starts at the fixed initial state $s_{\text{init}}$ and ends when the agent reaches the goal state $g$ (note that she might never reach the goal state). Success is measured by the agent’s regret over $K$ such episodes, that is the difference between her total cost over the $K$ episodes and the total expected cost of the optimal proper policy:

$$R_K = \sum_{k=1}^{K} \sum_{i=1}^{l^k} C_i^k - K \cdot \min_{\pi \in \Pi_{\text{proper}}} J^\pi(s_{\text{init}}),$$

where $l^k$ is the time it takes the agent to complete episode $k$ (which may be infinite), $C_i^k$ is the cost suffered in the $i$-th step of episode $k$ when the agent visited state-action pair $(s'_i, a'_i)$, and $\Pi_{\text{proper}}$ is the set of all stationary, deterministic and proper policies (that is not empty by assumption). In the case that $l^k$ is infinite for some $k$, we define $R_K = \infty$.

We denote the optimal proper policy by $\pi^\star$, $J^{\pi^\star}(s_{\text{init}}) = \arg \min_{\pi \in \Pi_{\text{proper}}} J^\pi(s_{\text{init}})$. Moreover, let $B_\star > 0$ be an upper bound on the values of $J^\pi^\star$ and let $T_\star > 0$ be an upper bound on the times $T^\pi^\star$, i.e., $B_\star \geq \max_{s \in S} J^\pi^\star(s)$ and $T_\star \geq \max_{s \in S} T^\pi^\star(s)$. Finally, let $D = \max_{s \in S} \min_{\pi \in \Pi_{\text{proper}}} T^\pi(s)$ be the SSP-diameter, and note that $B_\star \leq D \leq T_\star$.

### 2.1 Summary of our results

In Section 3 we present a novel black-box reduction from SSP to finite-horizon MDPs (Algorithm 1), that yields $\sqrt{K}$ regret bounds when combined with a certain class of optimistic algorithms for regret minimization in finite-horizon MDPs that we call admissible (Definition 1). The regret analysis for the reduction is described in Section 4, and in Section 5 we present an admissible algorithm for regret minimization in finite-horizon MDPs called ULCV1. We show that it guarantees the following optimal regret in the finite-horizon setting (stated formally in Theorem 5.1). Note that (for large enough number of episodes) this bound depends only on the expected cost of the optimal policy and not on the horizon $H$.

---

1. The initial state is fixed for simplicity of presentation, but it can be chosen adversarially at the beginning of every episode. Without any change to the algorithm or analysis, the same guarantees hold.
Theorem 2.1. Running ULCVI (Algorithm 1 in Section 5) in a finite-horizon MDP guarantees, with probability at least 1 − δ, a regret bound of
\[ O\left(\sqrt{(B_2^* + B_\star)|\mathcal{S}| |\mathcal{A}| K \log \frac{M|\mathcal{S}| |\mathcal{A}|}{\delta} + H^4 B_2^* |\mathcal{S}|^2 |\mathcal{A}| \log^{3/2} \frac{M|\mathcal{S}| |\mathcal{A}|}{\delta}\right), \]
for any number of episodes \( M \geq 1 \) simultaneously.

Combining ULCVI with our reduction yields the following minimax optimal regret bound for SSP.

Theorem 2.2. Running the reduction in Algorithm \[ \] with the finite-horizon regret minimization algorithm ULCVI ensures, with probability at least 1 − δ,
\[ R_K = O\left(\sqrt{(B_2^* + B_\star)|\mathcal{S}| |\mathcal{A}| K \log \frac{KT|\mathcal{S}| |\mathcal{A}|}{\delta} + T_2^2 B_2^* |\mathcal{S}|^2 |\mathcal{A}| \log^6 \frac{KT|\mathcal{S}| |\mathcal{A}|}{\delta}\right). \]

Remark 1. An important observation is that this regret bound is meaningful even for small \( K \). Unlike finite-horizon MDPs, where linear regret is trivial, in SSP ensuring finite regret is not easy. Our regret bound also implies that if we play for only one episode, i.e., we are only interested in the time it takes to reach the goal state, then it will take us at most \( \tilde{O}(T_2^2 B_2^* |\mathcal{S}|^2 |\mathcal{A}|) \) time steps to do so.

Remark 2. Note that our algorithm needs to know an upper bound on \( T_\star \) in advance. However, if all costs are strictly positive (i.e., at least \( c_{\min} > 0 \)), then there is a trivial upper bound of \( B_\star / c_{\min} \). In this case, our algorithm keeps an optimal regret bound for large enough \( K \), since the bound on \( T_\star \) only appears in the additive factor. Some previous work used a perturbation argument to generalize their results from the \( c_{\min} \) case to general costs [Tarbouriech et al., 2020, Rosenberg et al., 2020, Rosenberg and Mansour, 2020]. In our case, it will not work since the dependence on \( 1/c_{\min} \) in the additive term is too large. This may be an inherent shortcoming of using finite-horizon reduction to solve SSPs, as it also appears in the works of [Chen et al., 2020, Chen and Luc, 2021] for the adversarial setting.

Remark 3. In practice, one can think of \( T_\star \) as a parameter of the algorithm that controls computational complexity and the number of steps to complete \( K \) episodes. By choosing the parameter \( T_\star = x \) for example, we can guarantee that the regret bound of Theorem 2.2 holds against the best proper policy with expected time to the goal of at most \( x \) (assuming there exists one), and we can also guarantee that the total computational complexity of the algorithm is \( \tilde{O}(x K + \text{poly}(x, |\mathcal{S}|, |\mathcal{A}|)) \) steps to complete \( K \) episodes.

Remark 4. While the additive term in our regret bound is standard for most cases, it becomes large when \( B_\star \) is extremely small because of the dependence in \( B_2^* \). This was not an issue in previous work [Tarbouriech et al., 2020, Rosenberg et al., 2020] since they assumed that the costs are deterministic and known. We believe that this dependence is an artifact of our analysis that may be avoided with a more careful definition of \( \omega_A \) (see Definition 1) that depends on the actual cost in each state-action pair and not just \( B_\star \). Nevertheless, the main focus of this paper is on establishing that the minimax optimal regret for SSP is \( \tilde{O}(\sqrt{(B_2^* + B_\star)|\mathcal{S}| |\mathcal{A}| K}) \), and not on optimizing lower order terms. By that we also show that this is the minimax optimal regret for finite-horizon which is independent of the horizon \( H \) (up to logarithmic factors). Tightening the additive term and eliminating its dependence in \( B_2^* \) is left as an interesting future direction.

In Appendix D we prove that our regret bound is indeed minimax optimal. To complement the \( \Omega(B_\star \sqrt{|\mathcal{S}| |\mathcal{A}| K}) \) lower bound of Rosenberg et al., 2020 that assumes \( B_\star \geq 1 \), we provide the following tighter lower bound for the case that \( B_\star < 1 \).

Theorem 2.3. Let \( B_\star \leq \frac{1}{B_2^*} \). There exists an SSP problem instance \( \mathcal{M} = (\mathcal{S}, \mathcal{A}, P, c, s_{\text{init}}, g) \) in which \( J^\pi(s) \leq B_\star \) for all \( s \in \mathcal{S}, |\mathcal{S}| \geq 2, |\mathcal{A}| \geq 2, K \geq B_\star |\mathcal{S}| |\mathcal{A}|, \) such that the expected regret of any learner after \( K \) episodes satisfies
\[ \mathbb{E}[R_K] \geq \frac{1}{32} B_\star |\mathcal{S}| |\mathcal{A}| K^{1/2}. \]

3 A black-box reduction from SSP to finite-horizon

Our algorithm takes as input an algorithm \( \mathcal{A} \) for regret minimization in finite-horizon MDPs, and uses it to perform a black-box reduction. The algorithm is depicted below as Algorithm 1.
The algorithm breaks the individual time steps that comprise each of the $K$ episodes into intervals of $H$ time steps. If the agent reaches the goal state before $H$ time steps, we simply assume that she stays in $g$ until $H$ time steps are elapsed. We see each interval as one episode of a finite-horizon model $\tilde{M} = (\tilde{S}, \tilde{A}, \tilde{P}, \tilde{H}, \tilde{c}, \tilde{c}_g)$, where $\tilde{S} = S\cup\{g\}$ and $\tilde{c}_g : \tilde{S} \to \mathbb{R}$ is a set of terminal costs defined by $\tilde{c}_g(s) = 8B_s\mathbb{I}\{s \neq g\}$, where $\mathbb{I}\{s \neq g\}$ is the indicator function that equals 1 if $s \neq g$ and 0 otherwise. Moreover, $\tilde{P}, \tilde{c}$ are the natural extensions of $P, c$ to the goal state. That is, $\tilde{c}(s,a) = c(s,a)\mathbb{I}\{s \neq g\}$ and $$\tilde{P}(s' \mid s,a) = \begin{cases} P(s' \mid s,a), & s \neq g; \\ 1, & s = g, s' = g; \\ 0, & s = g, s' \neq g. \end{cases}$$

The horizon $H$ (which we will set to be roughly $T_+$) is chosen such that the optimal SSP policy will reach the goal state in $H$ time steps with high probability (recall that the expected hitting time of the optimal policy is bounded by $T_+$). The additional terminal cost is there to encourage the agent to reach the goal state within $H$ steps, which otherwise is not necessarily optimal with respect to the planning horizon.

### Algorithm 1: Reduction from SSP to Finite-Horizon MDP

1. **input:** state space $S$, action space $A$, initial state $s_{\text{init}}$, goal state $g$, confidence parameter $\delta$, number of episodes $K$, bound on the expected cost of the optimal policy $B_*$, bound on the expected time of the optimal policy $T$, and algorithm $A$ for regret minimization in finite-horizon MDPs.
2. **initialize** $\tilde{A}$ with state space $\tilde{S} = S \cup \{g\}$, action space $A$, horizon $H = 8T, \log(8K)$, confidence parameter $\delta/4$, terminal costs $\tilde{c}_g(s) = 8B_s\mathbb{I}\{s \neq g\}$ and bound on the expected cost of the optimal policy $9B_*$. 
3. **initialize** intervals counter $m \leftarrow 0$ and time steps counter $t \leftarrow 1$.
4. **for** $k = 1, \ldots, K$ **do**
5. **set** $s_t \leftarrow s_{\text{init}}$.
6. **while** $s_t \neq g$ **do**
7. **set** $m \leftarrow m + 1$, feed initial state $s_t$ to $\tilde{A}$ and obtain policy $\pi^m = \{\pi^m_h : \tilde{S} \to A\}_{h=1}^H$.
8. **for** $h = 1, \ldots, H$ **do**
9. play action $a_t = \pi^m_h(s_t)$, suffer cost $C_t \sim c(s_t, a_t)$, and set $s_{t+1}^m = s_t, a_{t+1}^m = a_t, c_{t+1}^m = C_t$.
10. **observe** next state $s_{t+1} \sim P(\cdot \mid s_t, a_t)$ and set $t \leftarrow t + 1$.
11. **if** $s_t = g$ **then**
12. pad trajectory to be of length $H$ and BREAK.
13. **end if**
14. **end for**
15. **set** $s_{t+1}^m = s_t$.
16. feed trajectory $U^m = (s_1^m, a_1^m, \ldots, s_{t+1}^m, a_{t+1}^m, s_{t+1}^m)$ and costs $\{C_t^m\}_{t=1}^H$ to $A$.
17. **end while**
18. **end for**

The algorithm $\tilde{A}$ is initialized with the state and action spaces as in the original SSP instance, the horizon length $H$, a confidence parameter $\delta/4$, a set of terminal costs $\tilde{c}_g$ and a bound on the expected cost of the optimal policy in the finite-horizon model $9B_*$. At the beginning of each interval, it takes as input an initial state and outputs a policy to be used throughout the interval. In the end of the interval it receives the trajectory and costs observed through the interval.

Note that while Algorithm 1 may run any finite-horizon regret minimization algorithm, in the analysis we require that $\tilde{A}$ possesses some properties (that most optimistic algorithms already have) in order to establish our regret bound. We specifically require $\tilde{A}$ to be an *admissible* algorithm—a model-based optimistic algorithm for regret minimization in finite-horizon MDPs, e.g., UCBVI [Azar et al., 2017] and EULER [Zanette and Brunskill, 2019]. Admissible algorithms are defined formally as follows.

**Definition 1.** A model-based algorithm $\tilde{A}$ for regret minimization in finite-horizon MDPs is called *admissible* if, when running $\tilde{A}$ with confidence parameter $\delta$, there is a good event that holds with probability at least $1 - \delta$, under which the following hold:
We can obtain a reasonable estimate (up to a constant multiplicative factor) of the cost-to-go from phases by reaching the goal state. In addition, we can apply our reduction while utilizing our first visits to each state in order to estimate its cost-to-go. Let denote its regret in M episodes by \( R \), and that \( R \) is a quantity that depends on the algorithm \( A \) and on the number of episodes, where \( M = K + \text{poly}(|S|, |A|, T, K) \) by Lemma 4.3. Our reduction directly inherits the computational complexity of the finite-horizon algorithm \( A \) in M episodes, where \( M = K + \text{poly}(|S|, |A|, T, K) \) by Lemma 4.3.

The computational complexity of ULCVI is \( O(|S|^3|A|^2 \log(MH)) \), and therefore our optimal regret for SSP is achieved in total computational complexity of \( O(|S|^3|A|^2 \log^2(KT,|S|A)) \) which is only logarithmic in the number of episodes.

### 3.1 Unknown expected optimal cost \( B \)

Inspired by techniques for estimation of the SSP-diameter in the adversarial SSP literature [Rosenberg and Mansour 2020, Chen and Luo 2021], in Appendix C we show that our reduction does not need to know \( B \) in advance, but can instead estimate it on the fly. We can obtain a reasonable estimate (up to a constant multiplicative factor) of the cost-to-go from state \( s \) by running the Bernstein-SSP algorithm of Rosenberg et al. 2020 for regret minimization in SSPs (that does not need to know \( B \)) with initial state \( s \) for roughly \( T^3|S|^2\) episodes. Thus, we can apply our reduction while utilizing our first visits to each state in order to estimate its cost-to-go. We operate in phases where each phase ends when some state is visited at least \( T^3|S|^2\) times, and all states that were not visited enough are treated as the goal state. Once we reach a poorly visited state, we simply run an episode of the corresponding Bernstein-SSP algorithm. Notice that this comes at a computational cost that is independent of the number of episodes \( K \) (since we use Bernstein-SSP for a small number of episodes), and in Appendix C we show that it achieves similar regret bounds with only an additional additive factor of \( O(T^3|S|^2A) \).

### 4 Regret analysis

In this section we prove Theorem 5.1. Below we give a high-level overview of the proofs and defer the details to Appendix A. We start the analysis with a regret decomposition that states that the SSP
regret can be bounded by the sum of two terms: the expected regret of the finite-horizon algorithm, and the deviation of the actual cost in each interval from its expected value. To that end, we use the notations: $M$ for the total number of intervals, $U^m = (s^m_1, a^m_1, \ldots, s^m_H, a^m_H, s^m_{H+1})$ for the trajectory visited in interval $m$, $C^m_h$ for the cost suffered in step $h$ of interval $m$, $\pi^m$ for the policy chosen by $A$ for interval $m$, and $\hat{J}^m_h(s)$ for the expected finite-horizon cost when playing policy $\pi$ starting from state $s$ in time step $h$.

**Lemma 4.1.** For $H = 8T_3 \log(8K)$, we have the following bound on the regret of Algorithm 1:

$$R_K \leq \hat{R}_A(M) + \sum_{m=1}^{M} \left( \sum_{h=1}^{H} C^m_h + \hat{c}_j(s^m_{h+1}) - \hat{J}^m_h(s^m_1) \right) + B_*.$$ \hspace{1cm} (1)

The bound in Eq. (1) is comprised of two summands and an additional constant. The first summand is an upper bound on the expected finite-horizon regret which we acquire by the admissibility of $A$ (Definition 1). Note that this bound is in terms of the number of intervals $M$ (i.e., the number of finite-horizon episodes) which is a random variable and not necessarily bounded. In what follows we show that, using the admissibility of $A$, we can actually bound $M$ by the number of SSP episodes $K$ plus a constant that depends on $\omega_A, |S|, |A|, T_*$ (but not on $K$). The second summand in Eq. (1) relates to the deviation of the total finite-horizon cost from its expected value.

The proof of Lemma 4.1 builds on two key ideas. The first is that, by setting $H$ to be $O(T_3 \log K)$, we ensure that the expected cost of the optimal policy in the SSP model $\hat{M}$ is close to that in the finite-horizon model $M$. The second idea is that if the agent does not reach the goal state in a certain interval, then she must suffer the terminal cost in the finite-horizon model. Therefore, although in a single episode there may be many intervals in which the agent does not reach the goal state, we can upper bound the cost in these extra intervals in $M$ by the corresponding terminal costs in $\hat{M}$.

Next, we bound the deviation of the actual cost in each interval from its expected value which appears as the second summand in Eq. (1). The bound is due to the following lemma.

**Lemma 4.2.** Assume that the reduction is performed using an admissible algorithm $A$. Then, the following holds with probability at least $1 - 3\delta_8$,

$$\sum_{m=1}^{M} \left( \sum_{h=1}^{H} C^m_h + \hat{c}_j(s^m_{h+1}) - \hat{J}^m_h(s^m_1) \right) = O\left( \sqrt{(B_*^2 + B_*)}M \log \frac{M}{\delta} + H\omega_A|S||A| \log \frac{MKT_*|S||A|}{\delta} \right).$$

The key observation here relies on the notion of unknown state-action pairs – pairs that were not visited at least $\omega_A$ times. After $\omega_A$ visits to some state-action pair $s, a$, we have a reasonable estimate of the next-state distribution $P(\cdot | s, a)$ therefore we can show that the expected accumulated cost in an interval until reaching an unknown state-action pair or the goal state is of order $B_*$ . Moreover, the second moment of this cost is of order $B_*^2 + B_*$. Thus, using Freedman inequality, we bound the deviation by $O(\sqrt{(B_*^2 + B_*)M})$, plus a cost of $O(H)$ for each “bad” interval in which we do not reach an unknown state-action pair or the goal state (there are roughly $\omega_A|S||A|$ such intervals).

Lastly, we need to bound the number of intervals $M$ to obtain a regret bound in terms of $K$ and not $M$ (notice that $M$ is a random variable that is not bounded a-priori).

**Lemma 4.3.** Assume that the reduction is performed using an admissible algorithm $A$. Then, with probability at least $1 - 3\delta_8$, $M \leq 4K + 4 \cdot 10^4|S||A|\omega_A \log(KT_*|S||A|\omega_A/\delta)$.

The proof shows that in every interval there is a constant probability to reach either the goal state or an unknown state-action pair. Leveraging this observation with a concentration inequality, we can bound the number of intervals by $O(K + \omega_A|S||A|H)$.

We can now prove a bound on the regret of Algorithm 1 using any admissible algorithm $A$.

**Proof of Theorem 2.7.** The regret bound of $A$, Lemmas 4.2 and 4.3 all hold with probability at least $1 - \delta$, via a union bound. Using Lemmas 4.1 and 4.2, we can write

$$R_K \leq \hat{R}_A(M) + O\left( \sqrt{(B_*^2 + B_*)M \log \frac{M}{\delta} + H\omega_A|S||A| \log \frac{MKT_*|S||A|}{\delta}} \right) + B_*.$$ 

Finally, we use Lemma 4.3 to bound $M$ by $4K + 4 \cdot 10^4|S||A|\omega_A \log(KT_*|S||A|\omega_A/\delta)$. \hfill $\square$
Algorithm 2 UPPPER LOWER CONFIDENCE VALUE ITERATION (ULCVI)

1: **input**: state space $S$, action space $A$, horizon $H$, confidence parameter $\delta$, terminal costs $\hat{c}_f$ and upper bound on the expected cost of the optimal policy $B_*$.  
2: **initialize**: $n^*(s, a) = 0$, $N^0(s, a, s') = 0$, $N^0(s, a) = 0$, $N^0(s, a, s', a') = 0 \forall (s, a, s') \in S \times A \times S$.  
3: **initialize**: $C(s, a) = 0$, $\hat{v}^0(s, a) = 0$, $\hat{P}^0(s' | s, a) = \mathbb{I}(s' = s) \forall (s, a, s') \in S \times A \times S$.  
4: **initialize**: PlanningTrigger = true.

27: Suffer terminal cost $\hat{c}_f(s^m_{H+1})$.  
28: end for

5 UPPPER LOWER CONFIDENCE VALUE ITERATION (ULCVI)

In this section we present the Upper Lower Confidence Value Iteration algorithm (ULCVI; Algorithm 2) for regret minimization in finite-horizon MDPs. This result holds independently of our SSP algorithm. Since the algorithm is similar to previous optimistic algorithms for the finite-horizon setting, e.g., UCBVI [Azar et al. 2017] and ORLC [Dann et al. 2019], we defer the analysis to Appendix B and focus on our technical novelty – bounding the regret in terms of the optimal value function and not the horizon.

In each episode $m$, the ULCVI algorithm maintains an optimistic lower bound $J^m_0(s)$ and a pessimistic upper bound $J^m_1(s)$ on the cost-to-go function of the optimal policy $J_\pi(s)$, and acts greedily with respect to the optimistic estimates. These optimistic and pessimistic estimates are computed based on the empirical transition function $\hat{P}^{m-1}(s' | s, a)$ and the empirical cost function $\hat{c}^{m-1}(s, a)$ to which we add an exploration bonus $b^m(s, a) + b^m_\ell(s, a)$, where $b^m$ handles the approximation error in the transitions and $b^m_\ell$ handles the approximation error in the costs. The bonuses are defined as follows,

$$b^m_\ell(s, a) = \sqrt{\frac{2\text{Var}_{\ell,m}^{m-1}(C) L_m}{\max\{1, n^m(s, a)\}} + \frac{5L_m}{\max\{1, n^m-1(s, a)\}}}$$

$$b^m(s, a) = \sqrt{\frac{2\text{Var}_{\ell,m}^{m-1}(C) L_m}{\max\{1, n^m(s, a)\}} + \frac{62H^2 B_c^2 |S| L_m}{\max\{1, n^m(s, a)\}} + \frac{B_*}{16H^2 \mathbb{E}[\hat{P}^{m-1}(s, a)]} [\hat{J}^{m}_{h+1}(s') - J^m_{h+1}(s')]},$$

where $L_m = 3 \log(3|S||A|Hm/\delta)$ is a logarithmic factor and $n^m(s, a)$ is the number of visits to $(s, a)$ in the first $m - 1$ episodes. Furthermore, $\text{Var}_{\ell,m}^{m-1}(C)$ is the empirical variance of the observed costs in $(s, a)$ in the first $m - 1$ episodes$^2$. Lastly, the term $\text{Var}_{\ell,m}^{m-1}(C) (\hat{J}^{m}_{h+1})$ is the variance of the

---

$^2$The empirical variance of $n$ numbers $a_1, \ldots, a_n$ is defined by $\frac{1}{n} \sum_{i=1}^n (a_i - \bar{a})^2$.
Algorithm 3 Optimistic-Pessimistic Value Iteration

1: input: $m^{-1}, F^{-1}, \hat{c}^{-1}, \hat{c}, B_{\star}$
2: initialize $J^m_{s,n}(s) = J^m_{s,n}(s) = \hat{c}_f(s)$ for all $s \in S$.
3: for $h = H, H - 1, \ldots, 1$ do
4:   for $s \in S$ do
5:     for $a \in A$ do
6:       set the bonus $b^m_{s,a} = b^m_{s,a} + b^m_{s,a}$ defined in Eq. (2).
7:     compute optimistic and pessimistic Q-functions:
8:     $Q^m_h(s, a) = \hat{c}^{-1}(s, a) - b^m_{s,a} + \mathbb{E}_{p^{\pi}(s,a)}[J^m_{h+1}^{\pi}(s')]$.
9: end for
10: $\hat{\pi}^m_h(s) = \arg\min_{a \in A} Q^m_h(s, a)$.
11: $J^m_h(s) = \max\{Q^m_h(s, \hat{\pi}^m_h(s)), 0\}$, $J^m_h(s) = \min\{Q^m_h(s, \hat{\pi}^m_h(s)), H\}$.
12: end for

next state value $J^m_{h+1}$ from state-action pair $(s, a)$, calculated via the empirical transition model, i.e.,

$\Var_{p^{\pi}(s,a)}[J^m_{h+1}^{\pi}(s')] = \mathbb{E}_{p^{\pi}(s,a)}[J^m_{h+1}^{\pi}(s')] - \mathbb{E}_{p^{\pi}(s,a)}[J^m_{h+1}^{\pi}(s')]^2$.

For improved computational complexity, we compute the optimistic policy only in episodes in which the number of visits to some state-action pair was doubled. This ensures that the number of optimistic policy computations grows only logarithmically with the number of episodes, i.e., it is bounded by $3|S||A|\log(MH)$. Since each optimal policy computation costs $O(H|S||A|)$ in the finite-horizon MDP model, our algorithm enjoys a total computational complexity of $O(H|S||A|^2 \log(MH))$.

For clarity, we keep the notation of the finite-horizon MDP as $\hat{M} = (S, A, \hat{P}, H, \hat{c}, \hat{c}_f)$, and let $B_{\star} = \max_{s, h} J^\pi_h(s)$ where $J^\pi$ is the value function of policy $\pi$ (in the case of our SSP reduction this parameter is simply $9B_{\star}$ by Lemma A.1). This implies that $\hat{c}_f(s) \leq B_{\star}$ for every $s$, and for simplicity, we assume that $B_{\star} \leq H$. Thus, the maximal total cost in an episode is bounded by $H + B_{\star} \leq 2H$. In Appendix B we prove the following high probability regret bound.

Theorem 5.1. ULCVI (Algorithm [2]) is admissible with the following guarantees:

(i) With probability at least $1 - \delta$, the regret bound of ULCVI is

$$\hat{R}_{ULCVI}(M) = O\left(\sqrt{(B_{\star}^2 + B_{\star})|S||A|\log \frac{MH|S||A| \log \frac{MH|S||A|}{\delta} + H^4 B_{\star}^{-1}|S||A|^2 \log^{3/2} \frac{MH|S||A|}{\delta}}{\delta}}\right)$$

for any number of episodes $M \geq 1$.

(ii) $\omega_{ULCVI} = O(H^4 B_{\star}^{-2}|S||A|)$.

Our analysis resembles the one in Efroni et al. [2021], and is adapted to the stationary MDP setting (i.e., the transition function does not depend on the time step $h$), and to the setting where we have costs instead of rewards, and terminal costs (which do not appear in previous work). By the definition of the algorithm and the regret bound in Theorem 5.1, it is clear that properties (i)-(iii) in Definition 1 of admissible algorithms hold. For property (iv), we use standard concentration inequalities and the definition of the bonuses in Eq. (2) in order to show it holds for $\omega_{ULCVI} = O(H^4 B_{\star}^{-2}|S||A|)$.

To obtain a regret bound whose leading term depends on $B_{\star}$ and not $H$, we start with a standard regret analysis for optimistic algorithms that establishes the regret scales with the square-root of the variance of the value functions of the agent’s policies, i.e.,

$$\hat{R}_{ULCVI}(M) \lesssim \sqrt{|S||A|} \sqrt{\sum_{m=1}^{M} \sum_{h=1}^{H} \Var_{p^{\pi}(s,a)}(J^m_{h+1}) + H^4 B_{\star}^{-1}|S|^2|A|}.$$
up to logarithmic factors and lower order terms. This can be further bounded by the second moment of the cumulative cost in each episode as follows,

\[
\hat{R}_{\text{ULCVI}}(M) \lesssim \sqrt{|S||A|} \left( \sum_{m=1}^{M} \mathbb{E} \left[ \sum_{h=1}^{H} C_{m}^h + \hat{c}(s_{m+1}) \right]^2 \left| \bar{U}^m \right| + H^4 B_*^4 |S|^2 |A| \right),
\]

where \( \bar{U}^m \) is the sequence of state-action pairs observed up to episode \( m \). Leveraging our techniques for the SSP reduction (but independently), we show that the second moment of the cumulative cost until an unknown state-action pair is reached can be bounded by \( O(B_*^2 + B_*^4) \). Therefore, we have at most \( O(H^4 B_*^2 |S|^2 |A|) \) episodes in which we bound the second moment trivially by \( O(H^2) \), and in the rest of the episodes we can bound it by \( O(B_*^2 + B_*^4) \). Together this yields the theorem as follows,

\[
\hat{R}_{\text{ULCVI}}(M) \lesssim \sqrt{|S||A|} \left( (B_*^2 + B_*^4)M + H^2 \cdot H^4 B_*^2 |S|^2 |A| \right) \lesssim \sqrt{(B_*^2 + B_*^4)|S||A|M + H^4 B_*^4 |S|^2 |A|}.
\]

A Proofs for Section 4

A.1 Proof of Lemma 4.1

In this section we relate the SSP regret and the finite-horizon regret, which relies on Lemmas A.1 and A.2 below that compare the cost-to-go function in the SSP $\mathcal{M}$ to the value function in the finite-horizon $\mathcal{M}$. To that end, we define a cost-to-go function with respect to the finite-horizon MDP $\tilde{\mathcal{M}}$ as: $\tilde{J}_h^*(s) = \mathbb{E} \left( \sum_{h'=h}^H c(s_{h'}, a_{h'}) \mid s_h = s \right)$, for any deterministic finite-horizon policy $\pi : S \times [H] \to A$.

**Lemma A.1.** Let $\pi$ be a stationary policy. For every $s \in \hat{S}$ and $h = 1, \ldots, H + 1$ it holds that

$$\tilde{J}_h^*(s) \leq J^*(s) + 8B_* \mathbb{P}[s_{H+1} \neq g \mid s_h = s, \tilde{P}, \pi].$$

**Proof.**

$$\tilde{J}_h^*(s) = \sum_{h'=h}^H \sum_{s' \in \hat{S}} \mathbb{P}[s_{h'} = s' \mid s_h = s, \tilde{P}, \pi] \hat{c}(s', \pi(s')) + \sum_{s' \in \hat{S}} \mathbb{P}[s_{H+1} = s' \mid s_h = s, \tilde{P}, \pi] \hat{c}(s')$$

$$= \sum_{h'=h}^H \sum_{s' \in \hat{S}} \mathbb{P}[s_{h'} = s' \mid s_h = s, P, \pi] c(s', \pi(s')) + 8B_* \mathbb{P}[s_{H+1} \neq g \mid s_h = s, \tilde{P}, \pi]$$

$$\leq \sum_{h'=h}^\infty \sum_{s' \in \hat{S}} \mathbb{P}[s_{h'} = s' \mid s_h = s, P, \pi] c(s', \pi(s')) + 8B_* \mathbb{P}[s_{H+1} \neq g \mid s_h = s, \tilde{P}, \pi]$$

$$= J^*(s) + 8B_* \mathbb{P}[s_{H+1} \neq g \mid s_h = s, \tilde{P}, \pi].$$

**Lemma A.2.** For every $s \in \hat{S}$, it holds that $J^{\pi^*}(s) \geq \tilde{J}_1^*(s) - \frac{B_*}{K}$.

**Proof.** The probability that $\pi^*$ does not reach the goal in $H$ steps is at most $1/(8K)$ due to [1112, Lemma 7]. Plugging that into Lemma A.1 yields the desired result.

**Proof of Lemma 4.7.** Consider the first interval of the first episode. If it ends in the goal state then

$$\sum_{i=1}^{\ell_1} C_i = \sum_{h=1}^H C_i^h + \hat{c}(g) = \sum_{h=1}^H C_i^h + \hat{c}(s_{H+1}^h).$$

If the agent did not reach $g$ in the first interval, then the agent also suffered the $8B_*$ terminal cost and thus

$$\sum_{i=1}^{\ell_1} C_i = \sum_{h=1}^H C_i^h + \hat{c}(s_{H+1}^h) + \sum_{i=H+1}^{\ell_1} C_i - \hat{c}(s_{H+1}^i)$$

$$= \sum_{h=1}^H C_i^h + \hat{c}(s_{H+1}^h) + \sum_{i=H+1}^{\ell_1} C_i - 8B_*$$

$$\leq \sum_{h=1}^H C_i^h + \hat{c}(s_{H+1}^h) + \sum_{i=H+1}^{\ell_1} C_i - \tilde{J}_{H+1}^*(s_{H+1}^i),$$

where the last inequality follows by combining Lemma A.2 with our assumption that $J^{\pi^*}(s) \leq B_*$. Repeating this argument iteratively we get, for every episode $k$,

$$\sum_{i=1}^{\ell_i} C_i^k - J^{\pi^*}(s_{H+i}) \leq \sum_{i=1}^{\ell_i} C_i^k - \tilde{J}_{H+1}^*(s_{H+1}^i) + \frac{B_*}{K}$$

$$\leq \sum_{m \in M_k} \sum_{h=1}^H C_i^m + \hat{c}(s_{H+1}^m) - \tilde{J}_{H+1}^*(s_{H+1}^m) + \frac{B_*}{K}$$

$$= \sum_{m \in M_k} \left( \sum_{h=1}^H C_i^m + \hat{c}(s_{H+1}^m) - \tilde{J}_{H+1}^*(s_{H+1}^m) \right) + \sum_{m \in M_k} \left( \tilde{J}_{H+1}^*(s_{H+1}^m) + \frac{B_*}{K} \right).$$
where $M_k$ is the set of intervals that are contained in episode $k$, and the first inequality follows from Lemma [A.2]. Summing over all episodes obtains

$$R_K \leq \sum_{m=1}^{M} \left( \sum_{h=1}^{H} C_h^m + \hat{c}_h(s_{H+1}^m) - \tilde{J}_{h}^m(s_1^m) \right) + \sum_{m=1}^{M} \left( \tilde{J}_{h}^m(s_1^m) - \hat{J}_{h}^m(s_1^m) \right) + \frac{B_{\delta}}{K}.$$ 

Notice that the second summand in the bound above is exactly the expected finite-horizon regret over the $M$ intervals. We finish the proof of the lemma by using the regret guarantees of $A$ (Definition 1).

\[ \square \]

## A.2 Proof of Lemma 4.2

In this section we bound the deviation of the actual cost in each interval from its expected value. To do that, we apply Lemma [A.3] below to bound the second moment of the cumulative cost in an interval up until an unknown state-action pair or the goal state were reached. Here $\hat{U}^m$ denotes the union of all information prior to the $m$th interval together with the first state of the $m$th interval (more formally, $\{\hat{U}^m\}_{m \geq 1}$ is a filtration). Moreover, we denote by $h_m$ the last time step before an unknown state-action pair or the goal state were reached in interval $m$ (or $H$ if they were not reached).

### Lemma A.3

Let $m$ be an interval and assume that the reduction is performed using an admissible algorithm $A$. If the good event of $A$ holds until the beginning of interval $m$, then the agent reaches the goal state or an unknown state-action pair with probability at least $1 - \frac{1}{2}$. Moreover, denote by $C^m = \sum_{h=1}^{h_m} C_h^m + \hat{c}_h(s_{H+1}^m)$ the cumulative cost in the interval until time $h_m$. Then, $\mathbb{E}[(C^m)^2 | \hat{U}^m] \leq 2 \cdot 10^2 B^2_\delta + 4B_\delta$.

#### Proof

The result is given by bounding the total expected cost suffered by the agent in another MDP (defined below) where all unknown state-action pairs are contracted with the goal state. The cost in this MDP is exactly $C^m$ by definition.

Let $\pi^m$ be the optimistic policy chosen by the algorithm for interval $m$. Consider the following finite-horizon MDP $\mathcal{M}^m = (\hat{S}, A, \hat{P}^m, H, \hat{c}, \hat{c}_h)$ that contracts unknown state-action pairs with the goal:

$$\hat{P}^m_{h}(s' | s, a) = \begin{cases} 0, & (s', \pi_{h+1}^m(s')) \text{ is unknown;} \\ P(s' | s, a), & s' \neq g \text{ and } (s', \pi_{h+1}^m(s')) \text{ is known;} \\ 1 - \sum_{s'' \in \hat{S}} \hat{P}^m_h(s'' | s, a), & s' = g. \end{cases}$$

Denote by $\hat{J}^m$ the cost-to-go function of $\pi^m$ in the finite-horizon MDP $\mathcal{M}^m$. Further, let $\hat{P}^m$ be the transition function induced by $\hat{P}^m$ in the MDP $\mathcal{M}^m$ similarly to $\hat{P}^m$, and $\hat{J}^m$ the cost-to-function of $\pi^m$ with respect to $\hat{P}^m$ (and with cost function $\hat{c}^m$). Notice that $\pi^m$ can only reach the goal state quicker in $\mathcal{M}^m$ than in $\mathcal{M}$, so that $\hat{J}^m_s(s) \leq J^m_s(s) \leq \hat{J}^m_s(s)$ for any $s \in \hat{S}$. By the value difference lemma (see, e.g., Shani et al., 2020), for every $s, h$ such that $(s, \pi_h^m(s))$ is known,

$$J^m_h(s) = \hat{J}^m_h(s) + \sum_{h' = h}^{H} \mathbb{E} \left[ \hat{c}(s_{h'}, a_{h'}) - \hat{c}_{h'}(s_{h'}, a_{h'}) \mid s_h = s, \hat{P}^m, \pi^m \right]$$

$$+ \sum_{h' = h}^{H} \mathbb{E} \left[ (\hat{P}^m_{h'}(s_{h'} \mid s_{h'}, a_{h'}) - \hat{P}^m_h(s_{h'} \mid s_{h'}, a_{h'})) \cdot J^m_h(s_h = s, \hat{P}^m, \pi^m) \right]$$

\[ \leq \hat{J}^m_h(s) + H \max_{(s, \pi_h^m(s)) \text{ known}} \left| \hat{c}(s, \pi_h^m(s)) - \hat{c}_{h}(s, \pi_h^m(s)) \right| + \left| \hat{J}^m(s) \right|_{\infty} \max_{(s, \pi_h^m(s)) \text{ known}} \left| \hat{P}(s_{h'} \mid s, \pi_h^m(s)) - \hat{P}_h(s_{h'} \mid s, \pi_h^m(s)) \right|_{1} \]

\[ \leq \hat{J}^m_h(s) + H \max_{(s, \pi_h^m(s)) \text{ known}} \left| \hat{c}(s, \pi_h^m(s)) - \hat{c}_{h}(s, \pi_h^m(s)) \right| \]

$$+ H \left| \hat{J}^m(s) \right|_{\infty} \max_{(s, \pi_h^m(s)) \text{ known}} \left| \hat{P}(s_{h'} \mid s, \pi_h^m(s)) - \hat{P}_h(s_{h'} \mid s, \pi_h^m(s)) \right|_{1}$$

$$\leq \hat{J}^m_h(s) + H \max_{(s, \pi_h^m(s)) \text{ known}} \left| \hat{c}(s, \pi_h^m(s)) - \hat{c}_{h}(s, \pi_h^m(s)) \right| + 9HB \max_{(s, \pi_h^m(s)) \text{ known}} \left| \hat{P}(s_{h'} \mid s, \pi_h^m(s)) - \hat{P}_h(s_{h'} \mid s, \pi_h^m(s)) \right|_{1},$$

where $B_{\delta}$ is the maximal absolute error of the value function approximation. This completes the proof.
Thus we arrived at
\[ C \leq \sum_{i=1}^{H-1} C_h + \hat{c}(s_{H+1}) \]

and iterating this argument yields
\[ E[(\hat{C})^2] \leq E\left[ \sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}(s_{H+1}) \right]^2 + E\left[ \sum_{h=1}^{H} \hat{c}(s_h, a_h) \right] \]

Here, the second summand equals \( J_{n}^{m}(s_1) \) which is at most \( 4B_* \).

Next, for the first summand, we split the time steps into \( Q \) blocks as follows. We denote by \( t_1 \) the first time step in which we accumulated a total cost of at least \( 11B_* \) (or \( H + 1 \) if it did not occur), by \( t_2 \) the first time step in which we accumulated a total cost of at least \( 11B_* \) after \( t_1 \), and so on up until \( t_Q = H + 1 \). Then, the first block consists of time steps \( t_0 = 1, \ldots, t_1 - 1 \), the second block consists of time steps \( t_1, \ldots, t_2 - 1 \), and so on. Since \( J_{n}^{m}(s) \leq 11B_* \) we must have \( \hat{c}(s_h, a_h) \leq 11B_* \) for all \( h = 1, \ldots, H \) and thus in every such block the total cost is between \( 11B_* \) and \( 22B_* \). Thus,
\[ E\left[ \left( \sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}(s_{H+1}) \right)^2 \right] \geq E\left[ \sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}(s_{H+1}) \right]^2 \]
\[ = E\left[ \sum_{i=0}^{Q-1} \sum_{h=t_i}^{t_{i+1}-1} \hat{c}(s_h, a_h) + \hat{c}(s_{H+1}) \right]^2 \]
\[ \geq E[11B_*Q]^2 = 121B_*^2E[Q]^2. \]
by Jensen’s inequality. On the other hand,

\[
E\left[\left(\sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}_f(s_{H+1})\right)^2\right] = E\left[\left(\sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}_f(s_{H+1}) - J^m_1(s_1) + J^m_1(s_1)\right)^2\right]
\]

\[
\leq 2E\left[\left(\sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}_f(s_{H+1}) - J^m_1(s_1)\right)^2\right] + 2J^m_1(s_1)^2
\]

\[
\leq 2E\left[\left(\sum_{h=0}^{Q-1} \sum_{h=t_i} \hat{c}(s_h, a_h) - J^m(s_i) + J^m(s_{t_i+1})\right)^2\right] + 32B^2_{\epsilon}
\]

\[
\overset{(a)}{=} 4E\left[\left(\sum_{h=0}^{Q-1} \sum_{h=t_i} \hat{c}(s_h, a_h) - J^m(s_i) + J^m(s_{t_i+1})\right)^2\right] + 32B^2_{\epsilon}
\]

\[
\leq 4E\left[Q \cdot (33B_{\epsilon})^2\right] + 32B^2_{\epsilon} \leq 4356B^2_{\epsilon}E[Q] + 32B^2_{\epsilon}.
\]

For (a) we used the fact that \(E[\sum_{h=t_i} \hat{c}(s_h, a_h) - J_i(s_i) + J_{t_i+1}(s_{t_i+1})] = 0\) using the Bellman optimality equations and conditioned on all past randomness up until time \(t_i\), and the fact that \(t_{i+1}\) is a (bounded) stopping time by the optional stopping theorem, in the following manner,

\[
E\left[\sum_{h=0}^{Q-1} \sum_{h=t_i} \hat{c}(s_h, a_h) - J^m(s_i) + J^m(s_{t_i+1})\right] = E\left[\sum_{h=0}^{Q-1} \sum_{h=t_i} \hat{c}(s_h, a_h) - J^m(s_i) + J^m(s_{t_i+1})\right]
\]

\[
= E\left[\sum_{h=t_i} \hat{c}(s_h, a_h) - J^m(s_i) + J^m(s_{t_i+1}) \mid s_1, \ldots, s_{t_i}\right]
\]

\[
= E\left[\sum_{h=t_i} \hat{c}(s_h, a_h) + E\left[J^m(s_{t_i+1}) \mid s_h\right] - J^m(s_i)\right] = 0.
\]

Thus, we have \(121B^2_{\epsilon}E[Q]^2 \leq 4356B^2_{\epsilon}E[Q] + 32B^2_{\epsilon}\), and solving for \(E[Q]\) we obtain \(E[Q] \leq 37\), so

\[
E\left[\left(\sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}_f(s_{H+1})\right)^2\right] \leq 2 \cdot 10^5 B^2_{\epsilon},
\]

and therefore

\[
E[(\hat{C})^2] \leq E\left[\left(\sum_{h=1}^{H} \hat{c}(s_h, a_h) + \hat{c}_f(s_{H+1})\right)^2\right] + E\left[\sum_{h=1}^{H} \hat{c}(s_h, a_h)\right] \leq 2 \cdot 10^5 B^2_{\epsilon} + 4B_{\epsilon}. \quad \square
\]

**Proof of Lemma 4.2** Recall that \(h_m\) is the last time step before an unknown state-action pair or the goal state were reached (or \(H\) if they were not reached) in interval \(m\), and let \(G^m\) be the event that the good event of algorithm \(A\) holds up to the beginning of interval \(m\). We start by decomposing the sum as follows

\[
\sum_{m=1}^{M} \left(\sum_{h_1}^{H} c^m_h + \hat{c}_f(s^m_{H+1}) - J^m_1(s^m_1)\right) \mathbb{I}\{G^m\} = \sum_{m=1}^{M} \left(\sum_{h_1}^{H} c^m_h + \hat{c}_f(s^m_{H+1})\right) \mathbb{I}\{h_m = H\} - \sum_{m=1}^{M} \left(\sum_{h_1}^{H} c^m_h + \hat{c}_f(s^m_{H+1})\right) \mathbb{I}\{h_m = H\} - \sum_{m=1}^{M} \left(\sum_{h=0}^{Q-1} \sum_{h=t_i} \hat{c}(s_h, a_h) - J^m(s_i) + J^m(s_{t_i+1})\right) \mathbb{I}\{G^m\}.
\]

The second term is trivially bounded by \((H + 8B_{\epsilon})||\text{SA}\|\omega_A \log \frac{M||\text{SA}\|\omega_A}{\delta}\) since every state-action pair becomes known after \(\omega_A \log \frac{M||\text{SA}\|\omega_A}{\delta}\) visits. Next, since

\[
E\left[\sum_{h=1}^{h_m} c^m_h + \hat{c}_f(s^m_{H+1})\right] \mathbb{I}\{h_m = H\} \mathbb{I}\{G^m\} = E\left[\sum_{h=1}^{h_m} c^m_h + \hat{c}_f(s^m_{H+1})\right] \mathbb{I}\{h_m = H\} \mathbb{I}\{G^m\} \leq \hat{J}^m_1(s^m_1) \mathbb{I}\{G^m\},
\]

16
the first term is bounded by \( \sum_{m=1}^{M} X^m \) where
\[
X^m = \left( \sum_{h=1}^{h_n} C_{h}^m + c_j(s_{H+1}) \mathbb{I}[h_m = H] \right) - \mathbb{E} \left[ \sum_{h=1}^{h_n} C_{h}^m + c_j(s_{H+1}) \mathbb{I}[h_m = H] \mid U^m \right] \mathbb{I}[G^m]
\]
is a martingale difference sequence bounded by \( H + 8B_\ast \) with probability 1. For any fixed \( M = m \), by Freedman’s inequality (Lemma E.1), we have with probability at least \( 1 - \frac{\delta}{8m(m+1)} \),
\[
\sum_{m'=1}^{m} X^{m'} \leq \eta \sum_{m'=1}^{m} \mathbb{E}[(X^{m'})^2 \mid U^{m'}] + \frac{\log(8m(m+1)/\delta)}{\eta}
\]
for any \( \eta \in (0, 1/(H + 8B_\ast)) \). By Lemma A.3 for some universal constant \( \alpha > 0 \), that
\[
\sum_{m'=1}^{m} \mathbb{E}[(X^{m'})^2 \mid U^{m'}] \leq \alpha m(B_\ast^2 + B_\ast),
\]
and setting \( \eta = \min \left\{ \sqrt{\frac{\log(8m(m+1)/\delta)}{B_\ast^2 + B_\ast m}}, \frac{1}{H + 8B_\ast} \right\} \) obtains
\[
\sum_{m'=1}^{m} X^{m'} \leq O \left( \sqrt{(B_\ast^2 + B_\ast)m \log \frac{m}{\delta} + (H + B_\ast) \log \frac{m}{\delta}} \right).
\]
Taking a union bound on all values of \( m = 1, 2, \ldots \) that the inequality above holds for all such values of \( m \) simultaneously with probability at least \( 1 - \delta/8 \). In particular, with probability at least \( 1 - \delta/8 \), we have
\[
\sum_{m=1}^{M} X^m \leq O \left( \sqrt{(B_\ast^2 + B_\ast)M \log \frac{M}{\delta} + (H + B_\ast) \log \frac{M}{\delta}} \right).
\]
The proof is concluded via a union bound—both Freedman inequality and the good event of \( A \) hold with probability at least \( 1 - \frac{\delta}{8} \), and this implies \( \mathbb{I}[G^m] = 1 \) for every \( m \).

A.3 Proof of Lemma 4.3

In this section we bound the number of intervals \( M \) with high probability for any admissible algorithm. To that end, we first define the notion of unknown state-action pairs. A state-action pair is defined as unknown if the number of times it was visited is at most \( \omega_A \log \frac{MH||SAI}{\delta} \) (and otherwise known).

**Proof of Lemma 4.3** Let \( G^m \) be the event that the good event of algorithm \( A \) holds up to the beginning of interval \( m \), and define \( X^m \) to be 1 if an unknown state-action pair or the goal state were reached during interval \( m \) (and 0 otherwise). Notice that \( \mathbb{E}[X^m \mid G^m] \leq \mathbb{E}[X^m \mid U^m] \geq \mathbb{I}[G^m] \) by Lemma A.3. Moreover, note that every state-action pair becomes known after \( \omega_A \log \frac{MH||SAI}{\delta} \) visits and therefore \( \sum_{m=1}^{M} X^m \leq \sum_{m=1}^{M} X^m \leq K + 110\|\omega_A \log \frac{MH||SAI}{\delta} \). By Lemma E.2, which is a consequence of Freedman’s inequality for bounded positive random variables, we have with probability at least \( 1 - \frac{\delta}{8} \) for all \( M \geq 1 \) simultaneously
\[
\sum_{m=1}^{M} \mathbb{I}[X^m \mid G^m] \leq 2 \sum_{m=1}^{M} \mathbb{I}[X^m] \geq 10 \log \frac{M}{\delta} \leq 2K + 110\|\omega_A \log \frac{MH||SAI}{\delta}.
\]
Using a union bound, this inequality and the good event of \( A \) both hold with probability at least \( 1 - \frac{\delta}{8} \). Then, \( \mathbb{I}[G^m] = 1 \) for all \( m \), and therefore
\[
\frac{M}{2} \leq 2K + 110\|\omega_A \log \frac{MH||SAI}{\delta}.
\]
Using the fact that \( x \leq a \log(bx) + c \rightarrow x \leq 6a \log(abc) + c \) for \( a, b, c \geq 1 \), this implies
\[
M \leq 4K + 4 \cdot 10^4\|\omega_A \log \frac{KT\|\omega_A}{\delta}.
\]
B Proofs for Section 5

Since all the proofs in this section refer to the finite-horizon setting (without a connection to SSP), we use the simpler notations \( M = (S, A, P, H, c, c_f) \) for the MDP, \( J^*_h(s) \) for the value function of policy \( \pi \), and \( B_s = \max_{s,h} J^*_h(s) \) for the upper bound on the value function of the optimal policy.

We define a state-action pair \((s,a)\) to be known if it was visited at least \( \alpha H^2 B^2 \) times (for some universal constant \( \alpha > 0 \) to be determined later), and otherwise unknown. In addition, we denote by \( h_m \) the last time step before an unknown state-action pair was reached (or \( H \) if they were not reached).

### B.1 The good event, optimism and pessimism

Throughout this section we use the notation \( a \lor 1 \) defined as \( \max\{a, 1\} \). In addition, we define the logarithmic factor \( L_m = 3 \log(6\pi\text{HmcHm}/\delta) \). Define the following events:

\[
E^c(m) = \{ \forall(s,a) : \|c^{m-1}(s,a) - c(s,a)\| \leq b^c_m(s,a) \}
\]

\[
E^{cv}(m) = \{ \forall(s,a) : \sqrt{\text{Var}_{s,a}^{m-1}(c)} - \sqrt{\text{Var}_{s,a}(c)} \leq \frac{12L_m}{n^{m-1}(s,a) \lor 1} \}
\]

\[
E^p(m) = \{ \forall(s,a,s') : |P(s'|s,a) - \bar{P}^{m-1}(s'|s,a)| \leq \frac{2P(s'|s,a)L_m}{n^{m-1}(s,a) \lor 1} + \frac{2L_m}{n^{m-1}(s,a) \lor 1} \}
\]

\[
E^{p1}(m) = \{ \forall(s,a,h) : |(\bar{P}^{m-1}(s,a) - P(s',a)) \cdot J_{h+1}^*| \leq \frac{2\text{Var}_{s,a}^{m-1}(J_{h+1}^*)L_m}{n^{m-1}(s,a) \lor 1} + \frac{5B_sL_m}{n^{m-1}(s,a) \lor 1} \}
\]

\[
E^{p2}(m) = \{ \forall(s,a,h) : \sqrt{\text{Var}_{s,a}^{m-1}(J_{h+1}^*)} - \sqrt{\text{Var}_{s,a}^{m-1}(J_{h+1}^*)} \leq \frac{12B_sL_m}{n^{m-1}(s,a) \lor 1} \}
\]

For brevity, we denote \( b^p_{m+1,h}(s,a) = \sqrt{2\text{Var}_{s,a}(J_{h+1}^*)L_m} + \frac{5B_sL_m}{n^{m-1}(s,a) \lor 1} \). This good event, which is the intersection of the above events, is the one used in Efroni et al. [2021]. The following lemma establishes that the good event holds with high probability. The proof is supplied in Efroni et al. [2021], Lemma 13] by applying standard concentration results.

**Lemma B.1 (The First Good Event).** Let \( G_1 = \cap_{m \geq 1} E^c(m) \cap_{m \geq 1} E^{cv}(m) \cap_{m \geq 1} E^p(m) \cap_{m \geq 1} E^{p1}(m) \cap_{m \geq 1} E^{p2}(m) \) be the basic good event. It holds that \( \mathbb{P}(G_1) \geq 1 - \frac{1}{4} \delta \).

Under the first good event, we can prove that the value is optimistic using standard techniques.

**Lemma B.2 (Upper Value Function is Optimistic, Lower Value Function is Pessimistic).** Conditioned on the first good event \( G_1 \), it holds that \( J^m(s) \leq J^*_h(s) \leq J^m(s) \) for every \( m = 1, 2, \ldots \), \( s \in S \) and \( h = 1, \ldots, H + 1 \).

**Proof.** Since \( J^*_h(s) \leq J^m(s) \) for any policy \( \pi \), we only need to prove the leftmost and rightmost inequalities of the claim. We prove this result via induction.

**Base case, the claim holds for** \( h = H + 1 \). Since we assume the terminal costs are known, for any \( s \in S \),

\[
J^m_{H+1}(s) = J^*_H(s) = J^m_H(s) = J^m(s) = c_f(s).
\]

**Induction step, prove for** \( h \in [H] \) **assuming the claim holds for all** \( h + 1 \leq h' \leq H + 1 \).

**Leftmost inequality, optimism.** Let \( a^*(s) \in \arg \min_{a \in A} Q^*_h(s,a) \), then

\[
J^*_h(s) - J^m(s) = Q^*_h(s, a^*(s)) - \max_{a \in A} \min_{m} Q^*_m(s,a), 0
\]
Assume that \( \min_{a} \mathcal{Q}^m_a(s, a) > 0 \) (otherwise, the inequality is satisfied). Then,

\[
\begin{align*}
(3) \quad & \geq \mathcal{Q}^m_a(s, a^*(s)) - \mathcal{Q}^m_a(s, a^*(s)) \\
& = c(s, a^*(s)) - c^{m-1}(s, a^*(s)) + b^m_p(s, a^*(s)) + b^m_p(s, a^*(s)) \\
& + (P - P^{m-1}) \cdot I(s, a^*(s)) \cdot J^m_{h+1} + \mathbb{E}^{P^{m-1} \cdot (s, a^*(s))} [J^m_{h+1}(s') - J^m_{h+1}(s')] \\
& \geq -b^m_p(s, a^*(s)) + b^m_p(s, a^*(s)),
\end{align*}
\]

where the last relation holds since the events \( \cap_{a} E^m_{1}(m) \) and \( \cap_{a} E^c_{1}(m) \) hold. We now analyze this term.

\[
\begin{align*}
(4) \quad & = -b^m_p(s, a^*(s)) + b^m_p(s, a^*(s)) \\
& \geq -\sqrt{2} \sqrt{\text{Var}_{P^{m-1}(s, a^*(s))}(J^m_{h+1})} L_m - \frac{5B_s L_m}{n^{m-1}(s, a^*(s)) \lor 1} \\
& \quad + \frac{17H^2B_s^{-1} L_m}{n^{m-1}(s, a^*(s)) \lor 1} \geq \frac{13H^2B_s^{-1} L_m}{n^{m-1}(s, a^*(s)) \lor 1} \\
& \quad + \frac{B_s}{16H^2} \mathbb{E}^{P^{m-1}(s, a^*(s))} [J^m_{h+1}(s') - J^m_{h+1}(s')] + \frac{B_s}{16H^2} \mathbb{E}^{P^{m-1}(s, a^*(s))} [J^m_{h+1}(s') - J^m_{h+1}(s')] \\
& \quad \geq \frac{13H^2B_s^{-1} L_m}{n^{m-1}(s, a^*(s)) \lor 1} + \frac{13H^2B_s^{-1} L_m}{n^{m-1}(s, a^*(s)) \lor 1} \\
& \quad \geq 0,
\end{align*}
\]

where \( a \) holds by plugging the definition of the bonuses \( b^m_{p+1, h} \) and \( b^m_p \) (recall Eq. (2)), as \(|S| \geq 1\) by assumption, and by the induction hypothesis \( J^m_{h+1} \geq J^m_{h+1} \). \( b \) holds by Lemma \( B.11 \) while setting \( a = 16H^2B_s^{-1} \) and bounding \( (5 + a/2)B_s \leq 13H^2 \). Combining all the above we conclude the proof of the rightmost inequality since \( J^m_{h+1} - J^m_{h+1} \geq (5) \geq (4) \geq 0 \).

**Rightmost inequality, pessimism.** The following relations hold.

\[
J^m_{h+1} - J^m_{h} = \mathcal{Q}^m_a(s, \pi^m_a(s)) - \min \left\{ \mathcal{Q}^m_a(s, \pi^m_a(s)), H \right\},
\]

Assume that \( \mathcal{Q}^m_a(s, \pi^m_a(s)) < H \) (otherwise, the claim holds). Then,

\[
\begin{align*}
(5) \quad & = \mathcal{Q}^m_a(s, \pi^m_a(s)) - \mathcal{Q}^m_a(s, \pi^m_a(s)) \\
& = c(s, \pi^m_a(s)) - c^{m-1}(s, \pi^m_a(s)) - b^m_p(s, \pi^m_a(s)) - b^m_p(s, \pi^m_a(s)) \\
& + (P - P^{m-1}) \cdot I(s, \pi^m_a(s)) \cdot J^m_{h+1} + \mathbb{E}^{P^{m-1}(s, \pi^m_a(s))} [J^m_{h+1}(s') - J^m_{h+1}(s')] \\
& \leq -b^m_p(s, \pi^m_a(s)) + (P - P^{m-1}) \cdot I(s, \pi^m_a(s)) \cdot J^m_{h+1},
\end{align*}
\]
We now focus on the last term. Observe that

\[(P - \bar{P}^{m-1})(1, s, \pi_h^m(s)) \cdot J_{h+1}^m \leq b_{p1,l}(s, \pi_h^m(s)) + (P - \bar{P}^{m-1})(1, s, \pi_h^m(s)) \cdot (J_{h+1}^m - J_{h+1}^{m-1})\]

where (a) holds by applying Lemma B.13 while setting \(\alpha = 32H^2B_1^{-1}, C_1 = 2, C_2 = 2\) and bounding \(2C_2 + \alpha \text{SLC}_1/2 \leq 36H^2B_1^{-1}\) (assumption holds since \(\cap_m E^m\) holds), (b) holds by the induction hypothesis, and (c) holds by plugging in \(b_{p1,l}^m\). Plugging this back into (6) and plugging the explicit form of the bonus \(b_{p1,l}^m(s, a)\) we get

\[\leq \sqrt{2L_m} \sqrt{\text{Var}_{P_{b,\pi_h^m}(s)}(J_{h+1}^m)} - \sqrt{\text{Var}_{P_{b,\pi_h^m}(s)}(J_{h+1}^m)}\]

\[= \frac{21H^2B_1^{-1}L_m}{n_{h+1}^{-1}(s, \pi_h^m(s))} - \frac{B_+}{32H^2} \text{E}_{P_{b,\pi_h^m}(s)}(J_{h+1}^m - J_{h+1}^{m-1})\]

where the last inequality holds by Lemma B.11 while setting \(\alpha = 32H^2B_1^{-1}\) and bounding \((5 + \alpha/2)B_+ \leq 21H^2B_1^{-1}\). Combining all the above we conclude the proof as

\[J_{h}^m - J_{h+1}^m \leq 5 \leq 6 \leq 0.\]

Finally, using similar techniques to [Efroni et al. 2021], we can prove an additional high probability bounds which hold alongside the basic good event \(G_1\).

**Lemma B.3 (The Good Event).** Let \(G_1\) be the event defined in Lemma B.1 and define the following random variables.

\[Y_{1, h} = \tilde{J}_{h}^m(s_h^m) - J_{h+1}^m(s_h)\]

\[Y_{2, h} = \text{Var}_{P_{b,\pi_h^m}(s_h)}(J_{h+1}^m)\]

\[Y_{3} = \left( \sum_{h=1}^{H} c(h_n^m, a_n^m) + c_f(s_{h+1}^m) \right)^2\]

\[Y_{4} = \left( \sum_{h=1}^{h_n} c(s_n^m, a_n^m) + c_f(s_{h_n+1}^m) \mathbb{I}(h_n = H) \right)^2\]

\[Y_{5} = \sum_{h=1}^{h_n} c(s_n^m, a_n^m) + c_f(s_{h_n+1}^m) \mathbb{I}(h_n = H).\]
The second good event is the intersection of two events \(G_2 = E^{OP} \cap E^{Var} \cap E^{Sec1} \cap E^{Sec2} \cap E^{cost}\) defined as follows.

\[
E^{OP} = \left\{ \forall h \in [H], M \geq 1 : \sum_{m=1}^{M} \mathbb{E}[Y_{1,h}^m | \bar{U}^m_h] \leq 68H^2L_M + \left( 1 + \frac{1}{4H} \right) \sum_{m=1}^{M} Y_{1,h}^m \right\}
\]
\[
E^{Var} = \left\{ \forall M \geq 1 : \sum_{m=1}^{M} \sum_{h=1}^{H} Y_{2,h}^m \leq 16H^4L_M + 2 \sum_{m=1}^{M} \sum_{h=1}^{H} \mathbb{E}[Y_{2,h}^m | \bar{U}^m] \right\}
\]
\[
E^{Sec1} = \left\{ \forall M \geq 1 : \sum_{m=1}^{M} \mathbb{E}[Y_{3}^m | \bar{U}^m] \leq 68H^4L_M + 2 \sum_{m=1}^{M} Y_{3}^m \right\}
\]
\[
E^{Sec2} = \left\{ \forall M \geq 1 : \sum_{m=1}^{M} Y_{4}^m \leq 16H^4L_M + 2 \sum_{m=1}^{M} \mathbb{E}[Y_{4}^m | \bar{U}^m] \right\}
\]
\[
E^{cost} = \left\{ \forall M \geq 1 : \sum_{m=1}^{M} Y_{5}^m \leq 8HL_M + 2 \sum_{m=1}^{M} \mathbb{E}[Y_{5}^m | \bar{U}^m] \right\}.
\]

Then, the good event \(G = G_1 \cap G_2\) holds with probability at least \(1 - \delta\).

**Proof.** Event \(E^{OP}\). Fix \(h\) and \(M\). We start by defining the random variable \(W^m \equiv \| J^m_h(s) - \bar{J}^m(s) \| > 0 \forall h \in [H], s \in S\). Observe that \(Y_h^m\) is \(\bar{U}^m_h\) measurable and also notice that \(W^m\) is \(\bar{U}^m\) measurable, as both \(\bar{m}\) and \(J^m_h\) are \(U^m\)-measurable. Finally, define \(\bar{Y}^m = W^m Y^m_h\). Importantly, notice that \(\bar{Y}^m \in [0, 2H]\) almost surely, by definition of \(W^m\) and since \(J^m_h(s), \bar{J}^m(s) \in [0, 2H]\) by the update rule. Thus, using Lemma 29 with \(C = 2H \geq 1\), we get

\[
\sum_{m=1}^{M} \mathbb{E}[\bar{Y}_h^m | \bar{U}_h^m] \leq \left( 1 + \frac{1}{4H} \right) \sum_{m=1}^{M} \bar{Y}_h^m + 68H^2 \log \frac{2HM(M+1)}{\delta},
\]

with probability greater than \(1 - \delta\), and since \(W^m\) is \(\bar{U}^m\)-measurable, we can write

\[
\sum_{m=1}^{M} W^m \mathbb{E}[Y^m_h | \bar{U}^m_h] \leq \left( 1 + \frac{1}{4H} \right) \sum_{m=1}^{M} W^m Y^m_h + 68H^2 \log \frac{2HM(M+1)}{\delta}. \tag{7}
\]

Importantly, notice that under \(G_1\), it holds that \(W^m \equiv 1\) (by Lemma 29). Therefore, applying the union bound and setting \(\delta = \delta/(2HM(M+1))\) we get

\[
P(E^{OP} \cap G_1) \leq \sum_{h=1}^{H} \sum_{M=1}^{\infty} \mathbb{P} \left( \left\{ \sum_{m=1}^{M} \mathbb{E}[Y^m_h | \bar{U}^m_h] \geq \left( 1 + \frac{1}{4H} \right) \sum_{m=1}^{M} Y^m_h + 68H^2 \log \frac{2HM(M+1)}{\delta} \right\} \cap G_1 \right)
\]
\[
= \sum_{h=1}^{H} \sum_{M=1}^{\infty} \mathbb{P} \left( \left\{ \sum_{m=1}^{M} W^m \mathbb{E}[Y^m_h | \bar{U}^m_h] \geq \left( 1 + \frac{1}{4H} \right) \sum_{m=1}^{M} W^m Y^m_h + 68H^2 \log \frac{2HM(M+1)}{\delta} \right\} \cap G_1 \right)
\]
\[
\leq \sum_{h=1}^{H} \sum_{M=1}^{\infty} \mathbb{P} \left( \left\{ \sum_{m=1}^{M} W^m \mathbb{E}[Y^m_h | \bar{U}^m_h] \geq \left( 1 + \frac{1}{4H} \right) \sum_{m=1}^{M} W^m Y^m_h + 68H^2 \log \frac{2HM(M+1)}{\delta} \right\} \right)
\]
\[
\leq \sum_{h=1}^{H} \sum_{M=1}^{\infty} \frac{\delta}{2HM(M+1)} = \frac{\delta}{2},
\]

where the first relation is by a union bound, the second relation follows because \(W^m \equiv 1\) under \(G_1\), and the last relation is by (7). Finally, we have

\[
P(G) \leq P(G_2 \cap G_1) + 2P(G_1) \leq \frac{\delta}{2} + \frac{2\delta}{4} = \delta.
\]

Replacing \(\delta \rightarrow \delta/5\) implies that \(P(E^{OP} \cap G_1) \leq \frac{\delta}{10}\).
**Event** $E^{\text{Var}}$. Fix $h \in [H]$. Observe that $Y_{2,h}^m$ is $\tilde{U}^m$ measurable and that $0 \leq Y_{2,h}^m \leq 4H^2$. Applying the second statement of Lemma E.2 we get that

$$\sum_{m=1}^{M} Y_{2,h}^m \leq 2 \sum_{m=1}^{M} E[Y_{2,h}^m|\tilde{U}^m] + 16H^2 \log \frac{1}{\delta}.$$ 

By taking union bound, as in the proof of the first statement of the lemma on all $h \in [H]$ and summing over $h \in [H]$, we get that with probability at least $1 - \delta/10$ for all $M \geq 1$ it holds that

$$\sum_{m=1}^{M} \sum_{h=1}^{H} Y_{2,h}^m \leq 2 \sum_{m=1}^{M} \sum_{h=1}^{H} E[Y_{2,h}^m|\tilde{U}^m] + 16H^2 L_{M}.$$ 

**Event** $E^{\text{Sec}}_1$. Observe that $Y_{3}^m$ is $\tilde{U}^m$ measurable and that $0 \leq Y_{3}^m \leq 4H^2$. Applying the first statement of Lemma E.2 we get that

$$\sum_{m=1}^{M} E[Y_{3}^m|\tilde{U}^m] \leq 2 \sum_{m=1}^{M} Y_{3}^m + 50H^4 \log \frac{1}{\delta}.$$ 

By taking union bound we get that with probability at least $1 - \delta/10$ the event holds.

**Event** $E^{\text{Sec}}_2$. Observe that $Y_{4}^m$ is $\tilde{U}^m$ measurable and that $0 \leq Y_{4}^m \leq 4H^2$. Applying the second statement of Lemma E.2 we get that

$$\sum_{m=1}^{M} Y_{4}^m \leq 2 \sum_{m=1}^{M} E[Y_{4}^m|\tilde{U}^m] + 16H^2 \log \frac{1}{\delta}.$$ 

By taking union bound we get that with probability at least $1 - \delta/10$ the event holds.

**Event** $E^{\text{Cont}}$. Observe that $Y_{5}^m$ is $\tilde{U}^m$ measurable and that $0 \leq Y_{5}^m \leq 2H$. Applying the second statement of Lemma E.2 we get that

$$\sum_{m=1}^{M} Y_{5}^m \leq 2 \sum_{m=1}^{M} E[Y_{5}^m|\tilde{U}^m] + 8H \log \frac{1}{\delta}.$$ 

By taking union bound we get that with probability at least $1 - \delta/10$ the event holds.

**Combining all the above.** We bound the probability of $\mathcal{G}$ as follows:

$$\mathbb{P}(\mathcal{G}) \leq \mathbb{P}(\mathcal{G}_1) + \mathbb{P}(E^{\text{OP}} \cap \mathcal{G}_1) + \mathbb{P}(E^{\text{Var}}) + \mathbb{P}(E^{\text{Sec}}_1) + \mathbb{P}(E^{\text{Sec}}_2) + \mathbb{P}(E^{\text{Cont}}) \leq \frac{\delta}{2} + 5 \cdot \frac{\delta}{10} = \delta. \quad \square$$

**B.2 ULCVI is admissible**

By the definition of the algorithm and its regret bound in Theorem 5.1, it is clear that properties 1,2,3 of the admissible algorithm definition hold. Thus, it remains to show property 4 by bounding $\omega_{\text{ULCVI}}$. In order to show that $\omega_{\text{ULCVI}} = O(H^4 B^2 |S|)$, we need to show that if the number of visits to $(s,a)$ is at least $\alpha H^4 B^2 |S| \log \frac{M|S||A|}{\delta}$ (for a large enough universal constant $\alpha > 0$) then $\|P(\cdot | s,a) - \tilde{P}(\cdot | s,a)\|_1 \leq 1/(18H)$ and $c(s,a) - \tilde{c}(s,a) | \leq B_s/H$ (under the good event), where $P, \tilde{c}$ are the estimations used by the algorithm to compute its optimistic $Q$-function (i.e., these are the empirical transition estimate and the empirical cost estimate plus the bonus).

Indeed, by event $\cap_{m \in \mathcal{E}} E^\theta(m)$,

$$\|P(\cdot | s,a) - \tilde{P}(\cdot | s,a)\|_1 = \|P(\cdot | s,a) - \tilde{P}(\cdot | s,a)\|_1$$

$$\leq \sqrt{2|S| \log \frac{16M'H^4 |S||A|}{\alpha}} \frac{n(s,a)}{n(s,a)} + \frac{2|S| \log \frac{4M'H^4 |S||A|}{\alpha}}{n(s,a)}$$

$$\leq \frac{4B_s}{\sqrt{\alpha H^2}} + \frac{16B_s^2}{\alpha H^4} = \frac{1}{18H},$$

22
for $\alpha > 5800$, where the first inequality holds by Jensen inequality and since event $\cap_{m\geq 0}E^m(m)$ holds. By the definition of the exploration bonuses we have

$$|c(s, a) - \hat{c}_t(s, a)| \leq |c(s, a) - \bar{c}(s, a)| + b_c(s, a) + b_p(s, a)$$

$$\leq 3\frac{2B_c^2\log \frac{16M^3S^3_M\delta}{\alpha}}{n(s, a)} + \frac{72H^3B^*_1|S|\log \frac{16M^3S^3_M\delta}{\alpha}}{n(s, a)} + \frac{B_* \max_s J_{h+1}(s') - J_{h+1}(s')}{16H^2}$$

for $\alpha > 5800$.

Finally, note that although our algorithm does not update the policy in the beginning of every episode (only when the number of visits to some state-action pair is doubled), this only implies that the constant $\alpha$ needs to be doubled.

### B.3 Proof of Theorem 5.1

As in the proof of UCBVI, before establishing the proof of Theorem 5.1 we establish the following key lemma that bounds the on-policy errors at time step $h$ by the on-policy errors at time step $h + 1$ and additional additive terms. Given this result, the analysis follows with relative ease.

**Lemma B.4 (ULCBVI, Key Recursion Bound).** Conditioning on the good event $\mathcal{G}$, the following bound holds for all $h \in [H]$.

$$\sum_{m=1}^M J^m_h(s_h^m) - L^m_h(s_h^m) \leq 68H^2L_H + \sum_{m=1}^M \frac{310H^3B^*_1|S|L_m}{\sqrt{n(s_h^m, a_h^m)} \vee 1} + \sum_{m=1}^M \frac{4\sqrt{L_m}}{n(s_h^m, a_h^m) \vee 1} \left(1 + \frac{1}{2H} \right)^2 \sum_{m=1}^M (J^m_{h+1}(s_{h+1}^m) - L^m_{h+1}(s_{h+1}^m)).$$

**Proof.** We bound each of the terms in the sum as follows.

$$J^m_h(s_h^m) - L^m_h(s_h^m) = 2b_c^m(s_h^m, a_h^m) + 2b_p^m(s_h^m, a_h^m) + \mathbb{E}_{P_{\delta}}[|c_{s_h^m, a_h^m}^m|][J^m_{h+1}(s_{h+1}^m) - L^m_{h+1}(s_{h+1}^m)]$$

$$= 2b_c^m(s_h^m, a_h^m) + 2b_p^m(s_h^m, a_h^m) + \mathbb{E}_{P_{\delta}}[|c_{s_h^m, a_h^m}^m|][J^m_{h+1}(s_{h+1}^m) - L^m_{h+1}(s_{h+1}^m)] + (\bar{P}^m - P)(|c_{s_h^m, a_h^m}^m|)(J^m_{h+1} - L^m_{h+1})$$

$$\leq 2b_c^m(s_h^m, a_h^m) + 2b_p^m(s_h^m, a_h^m) + \frac{8H^2|S|L_m}{n(s_h^m, a_h^m) \vee 1} + \left(1 + \frac{1}{4H} \right) \mathbb{E}_{P_{\delta}}[|c_{s_h^m, a_h^m}^m|][J^m_{h+1}(s_{h+1}^m) - L^m_{h+1}(s_{h+1}^m)]$$

where the last relation hold by Lemma B.13, which upper bounds

$$(\bar{P}^m - P)(|c_{s_h^m, a_h^m}^m|)(J^m_{h+1} - L^m_{h+1}) \leq \frac{8H^2|S|L_m}{n(s_h^m, a_h^m) \vee 1} + \frac{1}{4H} \mathbb{E}_{P_{\delta}}[|c_{s_h^m, a_h^m}^m|][J^m_{h+1}(s_{h+1}^m) - L^m_{h+1}(s_{h+1}^m)]$$

by setting $\alpha = 4H, C_1 = C_2 = 2$ and bounding $H_{L_m}(2C_2 + \alpha|S|C_1/2) \leq 8H^2|S|L_m$ (the assumption of the lemma holds since the event $\cap_{m\geq 0}E^m(m)$ holds). Taking the sum over $m \in [M]$ we get that

$$\sum_{m=1}^M J^m_h(s_h^m) - L^m_h(s_h^m) \leq \sum_{m=1}^M 2b_c^m(s_h^m, a_h^m) + \sum_{m=1}^M 2b_p^m(s_h^m, a_h^m)$$

$$+ \sum_{m=1}^M \frac{8H^2|S|L_m}{n(s_h^m, a_h^m) \vee 1} + \sum_{m=1}^M \left(1 + \frac{1}{4H} \right) \mathbb{E}_{P_{\delta}}[|c_{s_h^m, a_h^m}^m|][J^m_{h+1}(s_{h+1}^m) - L^m_{h+1}(s_{h+1}^m)].$$

The first sum is bounded in Lemma B.5 by

$$\sum_{m=1}^M b_c^m(s_h^m, a_h^m) \leq \sum_{m=1}^M \sqrt{\frac{2c(s_h^m, a_h^m)L_m}{n(s_h^m, a_h^m) \vee 1}} + \sum_{m=1}^M 10L_m \sqrt{n(s_h^m, a_h^m) \vee 1}.$$
and the second sum is bounded in Lemma [B.6] by

\[ \sum_{m=1}^{M} b^m_n(s^m_n, a^m_n) \leq \sum_{m=1}^{M} \frac{139H^3B^{-1}_\epsilon|S|L^{m}_{\epsilon}}{n^{m-1}(s^m_n, a^m_n) \vee 1} + \sum_{m=1}^{M} \sqrt{2L_m \frac{\Var_P(u^*_n, u^*_m)(J^m_{n+1})}{n^{m-1}(s^m_n, a^m_n) \vee 1}} + \frac{1}{8H} \sum_{m=1}^{M} \mathbb{E}_P(u^*_n, u^*_m)[J^m_{n+1}(s^m_{n+1}) - J^m_{n+1}(s^m_{n+1})]. \]

Plugging this into (2) and rearranging the terms we get

\[ \sum_{m=1}^{M} J^m_{n}(s^m_n) - J^m_{n}(s^m_n) \leq \sum_{m=1}^{M} \frac{2\sqrt{2\epsilon(s^m_n, a^m_n)L_m}}{n^{m-1}(s^m_n, a^m_n) \vee 1} + \sum_{m=1}^{M} \frac{\Var_P(u^*_n, u^*_m)(J^m_{n+1})}{n^{m-1}(s^m_n, a^m_n) \vee 1} + \sum_{m=1}^{M} \mathbb{E}_P(u^*_n, u^*_m)[J^m_{n+1}(s^m_{n+1}) - J^m_{n+1}(s^m_{n+1})] \]

\[ \leq 68H^2L + \sum_{m=1}^{M} \frac{2\sqrt{L_m}}{n^{m-1}(s^m_n, a^m_n) \vee 1} + \sum_{m=1}^{M} \frac{286H^3B^{-1}_\epsilon|S|L_m}{n^{m-1}(s^m_n, a^m_n) \vee 1} + \sum_{m=1}^{M} \frac{\Var_P(u^*_n, u^*_m)(J^m_{n+1})}{n^{m-1}(s^m_n, a^m_n) \vee 1} + \left(1 + \frac{1}{2H}\right) \sum_{m=1}^{M} \frac{2\sqrt{H}J^m_{n+1}(s^m_{n+1}) - J^m_{n+1}(s^m_{n+1})}{n^{m-1}(s^m_n, a^m_n) \vee 1}, \]

where the last inequality follows since the second good event holds.

**Proof of Theorem 5.7** Start by conditioning on the good event which holds with probability greater than 1 − δ. Applying the optimism-pessimism of the upper and lower value function we get

\[ \sum_{m=1}^{M} J^m_{n}(s^m_n) - J^m_{n}(s^m_n) \leq \sum_{m=1}^{M} J^m_{n}(s^m_n) - J^m_{n}(s^m_n). \]

(10)

Iteratively applying Lemma [B.4] and bounding the exponential growth by \((1 + \frac{1}{2H})^{2H} \leq e \leq 3\), the following upper bound on the cumulative regret is obtained.

\[ \sum_{m=1}^{M} J^m_{n}(s^m_n) - J^m_{n}(s^m_n) \leq 204H^3B^{-1}_\epsilon|S|L + \sum_{m=1}^{M} \sum_{h=1}^{H} \frac{930H^3B^{-1}_\epsilon|S|L_m}{n^{m-1}(s^m_n, a^m_n) \vee 1} \]

\[ + \sum_{m=1}^{M} \sum_{h=1}^{H} \frac{12\sqrt{\epsilon(s^m_n, a^m_n)L_m}}{n^{m-1}(s^m_n, a^m_n) \vee 1} + 9 \sum_{m=1}^{M} \sum_{h=1}^{H} \frac{\sqrt{L_m \Var_P(u^*_n, u^*_m)(J^m_{n+1})}}{n^{m-1}(s^m_n, a^m_n) \vee 1}. \]

(11)

We now bound each of the three sums in Eq. (11). We bound the first sum in Eq. (11) via standard analysis as follows:

\[ \sum_{m=1}^{M} \sum_{h=1}^{H} \frac{H^3B^{-1}_\epsilon|S|L_m}{n^{m-1}(s^m_n, a^m_n) \vee 1} \leq H^3B^{-1}_\epsilon|S|L \sum_{m=1}^{M} \sum_{h=1}^{H} \frac{1}{n^{m-1}(s^m_n, a^m_n) \vee 1} \]

\[ = H^3B^{-1}_\epsilon|S|L \sum_{m=1}^{M} \sum_{s,a}^H \mathbb{I}\{s^m_n = s, a^m_n = a\} n^{m-1}(s, a) \vee 1 \]

\[ \leq H^3B^{-1}_\epsilon|S|L \sum_{m=1}^{M} \sum_{s,a}^H \mathbb{I}\{n^{m-1}(s, a) \geq H\} n^{m-1}(s, a) \vee 1 \]

\[ + 2H^4B^{-1}_\epsilon|S|^2|A|L_M \]

\[ \leq 3H^3B^{-1}_\epsilon|S|^2|A|L_M \log(MH) + 2H^4B^{-1}_\epsilon|S|^2|A|L_M, \]

where the last inequality is by Lemma [B.12] that bounds \(\sum_{m,s,a} \mathbb{I}\{n^{m-1}(s, a) \geq H\} n^{m-1}(s, a) \vee 1 \)

\[ \leq 3|S|^2|A| \log(MH). \]
The third sum in Eq. (11) is bounded as follows.

\[
\sum_{m=1}^{M} \sum_{h=1}^{H} \frac{c(s_h^m, a_h^m) L_m}{n^{m-1}(s_h^m, a_h^m)} \leq \sum_{m=1}^{M} \sum_{h=1}^{H} \frac{c(s_h^m, a_h^m) L_m}{n^{m-1}(s_h^m, a_h^m)} \mathbb{I}\{n^{m-1}(s_h^m, a_h^m) \geq H\} + 2H|\mathcal{S}| |\mathcal{A}| L_M
\]

\[
\leq \sqrt{L_M} \sum_{m=1}^{M} \sum_{h=1}^{H} c(s_h^m, a_h^m) \cdot \sum_{m=1}^{M} \sum_{h=1}^{H} \mathbb{I}\{n^{m-1}(s_h^m, a_h^m) \geq H\} + 2H|\mathcal{S}| |\mathcal{A}| L_M
\]

\[
\leq \sqrt{3|\mathcal{S}| |\mathcal{A}| L_M} \sum_{m=1}^{M} \sum_{h=1}^{H} c(s_h^m, a_h^m) + c_f(s_{h+1}^m) + 2H|\mathcal{S}| |\mathcal{A}| L_M
\]

\[
\leq O\left(\sqrt{B_1 |\mathcal{S}| |\mathcal{A}| L_M + H^3 B_*^{|\mathcal{A}|^2 |\mathcal{S}|^2 \log^{3/2} \frac{MH|\mathcal{S}| |\mathcal{A}|}{\delta}}\right).
\]

where (a) is by Cauchy-Schwartz, (b) is by Lemma B.12 and the last inequality is by Lemma B.7.

The third sum in Eq. (11) is bounded in Lemma B.8 by

\[
\sum_{m=1}^{M} \sum_{h=1}^{H} \frac{L_m \text{Var}_{\mathcal{S}, a_h^m}(J_{h+1}^m)}{n^{m-1}(s_h^m, a_h^m)} \leq \sum_{m=1}^{M} \sum_{h=1}^{H} \frac{\text{Var}_{\mathcal{S}, a_h^m}(J_{h+1}^m)}{n^{m-1}(s_h^m, a_h^m)} (L_m \text{ increasing in } m)
\]

\[
\leq \sqrt{L_m} \cdot O\left(\sqrt{B_1 |\mathcal{S}| |\mathcal{A}| L_M \log(MH) + H^3 B_*^{|\mathcal{A}|^2 |\mathcal{S}|^2 \log^{3/2} \frac{MH|\mathcal{S}| |\mathcal{A}|}{\delta}}\right). \quad \text{(Lemma B.8)}
\]

B.4 Bounds on the cumulative bonuses

Lemma B.5 (Bound on the Cumulative Cost Function Bonus). Conditioning on the good event the following bound holds for all \( h \in [H] \).

\[
\sum_{m=1}^{M} b_c^m(s_h^m, a_h^m) \leq \sum_{m=1}^{M} \sqrt{\frac{2c(s_h^m, a_h^m) L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1} + \sum_{m=1}^{M} \frac{10L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1.
\]

Proof. By definition of \( b_c^m \) and since the event \( \cap_m E^m(m) \) holds, we have

\[
\sum_{m=1}^{M} b_c^m(s_h^m, a_h^m) = \sum_{m=1}^{M} \sqrt{\frac{2\text{Var}_{s_h^m, a_h^m}(c) L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1} + \frac{5L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1
\]

\[
\leq \sum_{m=1}^{M} \sqrt{\frac{2\text{Var}_{s_h^m, a_h^m}(c) L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1} + \sqrt{\frac{2L_m |\text{Var}_{s_h^m, a_h^m}(c) - \text{Var}_{s_{h-1}^m, a_{h-1}^m}(c)|}{n^{m-1}(s_h^m, a_h^m)} \vee 1} + \frac{5L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1
\]

\[
\leq \sum_{m=1}^{M} \sqrt{\frac{2\text{Var}_{s_h^m, a_h^m}(c) L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1} + \frac{10L_m}{n^{m-1}(s_h^m, a_h^m)} \vee 1,
\]

where the first inequality holds since \( \sqrt{a + b} \leq \sqrt{a} + \sqrt{b} \). Finally, notice that for every \((s, a) \in S \times A\) the variance of the cost is bounded by the second moment, which is bounded by the expected value \( c(s, a) \) since the random cost value is bounded in \([0, 1]\).

\[\square\]
Lemma B.6 (Bound on the Cumulative Transition Model Bonus). Conditioning on the good event the following bound holds for all $h \in [H]$.

\[
\sum_{m=1}^{M} b^m_p(s^m_h, a^m_h) \leq \sum_{m=1}^{M} \frac{139H^2 B^*_m \sqrt{\text{SI}(m)}}{n^{m-1}(s^m_h, a^m_h) \lor 1} + \sum_{m=1}^{M} \sqrt{2L_m} \sqrt{\frac{\text{Var}(P_c(s^m_h, a^m_h) \downarrow I^+_m)}{n^{m-1}(s^m_h, a^m_h) \lor 1}} + \frac{1}{8H} \sum_{m=1}^{M} \mathbb{E}_{P_c(s^m_h, a^m_h)}[J^m_{h+1}(s^m_h) - J^m_{h+1}(s^m_h)].
\]

Proof. First, by applying Lemma [B.13] with $\alpha = 8H$, $C_1 = C_2 = 2$ and $HL_m(2C_2 + \alpha|\text{SI}|2) \leq 12H^2|\text{SI}|m$, we have

\[
\mathbb{E}_{P^{m-1}(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] = \mathbb{E}_{P_c(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] + (\mathbb{P}^{m-1} - P)(s, a) \cdot (J^m_{h+1} - J^m_{h+1})
\]

\[
\leq \frac{9}{8} \mathbb{E}_{P_c(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] + \frac{12H^2|\text{SI}|m}{n^{m-1}(s, a) \lor 1}. \tag{12}
\]

Thus, the bonus $b^m_p(s, a)$ can be upper bounded as follows.

\[
b^m_p(s, a) \leq \sqrt{2L_m} \sqrt{\frac{\text{Var}(P^{m-1}(s, a))}{n^{m-1}(s, a) \lor 1}} + \frac{1}{16H} \mathbb{E}_{P^{m-1}(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] + \frac{62H^2 B^*_m \sqrt{\text{SI}(m)}}{n^{m-1}(s, a) \lor 1}
\]

\[
\leq \sqrt{2L_m} \sqrt{\frac{\text{Var}(P^{m-1}(s, a))}{n^{m-1}(s, a) \lor 1}} + \frac{9}{128H} \mathbb{E}_{P_c(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] + \frac{74H^2 B^*_m \sqrt{\text{SI}(m)}}{n^{m-1}(s, a) \lor 1}. \tag{13}
\]

We bound the first term of (13) to establish the lemma. It holds that

\[
\sqrt{2L_m} \sqrt{\frac{\text{Var}(P^{m-1}(s, a))}{n^{m-1}(s, a) \lor 1}} = \sqrt{2L_m} \sqrt{\frac{\text{Var}(P^{m-1}(s, a))}{n^{m-1}(s, a) \lor 1}} - \frac{\text{Var}(P_c(s, a))}{n^{m-1}(s, a) \lor 1} + \frac{\text{Var}(P_c(s, a))}{n^{m-1}(s, a) \lor 1}
\]

\[
\leq \sqrt{2L_m} \sqrt{\frac{\text{Var}(P^{m-1}(s, a))}{n^{m-1}(s, a) \lor 1}} + \frac{\text{Var}(P_c(s, a))}{n^{m-1}(s, a) \lor 1}.
\]

Term (i) is bounded by Lemma [B.11] (by setting $\alpha = 32H$ and $(5 + \alpha/2)B^* m \leq 21H^2$).

\[
\sqrt{2L_m} \sqrt{\frac{\text{Var}(P^{m-1}(s, a))}{n^{m-1}(s, a) \lor 1}} \leq \frac{1}{32H} \mathbb{E}_{P^{m-1}(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] + \frac{21H^2 L_m}{n^{m-1}(s, a) \lor 1}.
\]

Following the same steps as in (12), we get

\[
\mathbb{E}_{P^{m-1}(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] \leq \frac{9}{8} \mathbb{E}_{P_c(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] + \frac{12H^2|\text{SI}|m}{n^{m-1}(s, a) \lor 1},
\]

and thus,

\[
(i) \leq \frac{9}{256H} \mathbb{E}_{P_c(s, a)}[J^m_{h+1}(s') - J^m_{h+1}(s')] + \frac{33H^2|\text{SI}|m}{n^{m-1}(s, a) \lor 1}.
\]

Term (ii) is bounded as follows.

\[
(ii) \leq \frac{\text{Var}(P_c(s, a))}{n^{m-1}(s, a) \lor 1} \quad \text{(By Lemma [B.5])}
\]

\[
\leq \frac{\mathbb{E}_{P_c(s, a)}[(J^m_{h+1}(s') - J^m_{h+1}(s'))^2]}{n^{m-1}(s, a) \lor 1}
\]

\[
\leq \frac{2H \mathbb{E}_P(s, a)}{n^{m-1}(s, a) \lor 1} \quad (0 \leq J^m_p(s') - \text{Var}^m_h(s') \leq 2H)
\]

\[
\leq \frac{1}{64H} \mathbb{E}_P(s, a)(J^m_{h+1}(s') - J^m_{h+1}(s')) + \frac{32H^2}{n^{m-1}(s, a) \lor 1}. \quad (ab \leq \frac{1}{4}a^2 + \frac{1}{4}b^2 \text{ for } \alpha = 64H)
\]
Thus, applying $\bar{J}_n^h \geq J_n^u \geq J_n^h$ (Lemma B.2) in the bounds of (i) and (ii) we get

$$b_m^n(s, a) \leq \frac{1}{8H} \mathbb{E}_{\mathcal{P}_k(s, a)}[(\bar{J}_n^m(s') - J_n^m(s'))] + \frac{139H^3B_+^2|S||A|\log \frac{MH|S||A|}{\delta} + \sqrt{2TM\sqrt{\text{Var}_{\mathcal{P}_k(s, a)}(J_m^u(s, a))}}}{\sqrt{h_{m-1}(s, a)}}. $$

and summing over $m$ concludes the proof.

**Lemma B.7** (Bound on Cost Term). *Conditioning on the good event, it holds that*

$$\sum_{m=1}^{M} \sum_{h=1}^{H} c(s_h^m, a_h^m) + c_f(s_{h+1}^m) \leq O \left( B_*M + H^5B_+^2|S||A|\log \frac{MH|S||A|}{\delta} \right). $$

*Proof.* Denote by $h_m$ the last time step before reaching an unknown state-action pair (or $H$ if it was not reached). By the event $E_{\text{con}}$ we have

$$\sum_{m=1}^{M} \sum_{h=1}^{H} c(s_h^m, a_h^m) + c_f(s_{h+1}^m) = \sum_{m=1}^{M} \left( \sum_{h=h_m+1}^{H} c(s_h^m, a_h^m) + c_f(s_{h+1}^m)\mathbb{I}\{h_m \neq H\} \right) $$

$$+ \sum_{m=1}^{M} \left( \sum_{h=1}^{h_m} \sum_{h=1}^{h_m} c(s_h^m, a_h^m) + c_f(s_{h+1}^m)\mathbb{I}\{h_m = H\} \right) $$

$$\leq 2\alpha H^3B_+^2|S||A|\log \frac{MH|S||A|}{\delta} + \sum_{m=1}^{M} \left( \sum_{h=1}^{h_m} \sum_{h=1}^{h_m} c(s_h^m, a_h^m) + c_f(s_{h+1}^m)\mathbb{I}\{h_m = H\} \right) $$

$$\leq 10\alpha H^3B_+^2|S||A|\log \frac{MH|S||A|}{\delta} + 2 \sum_{m=1}^{M} \mathbb{E} \left[ \sum_{h=1}^{h_m} \sum_{h=1}^{h_m} c(s_h^m, a_h^m) + c_f(s_{h+1}^m)\mathbb{I}\{h_m = H\} \mid \bar{U}_m \right] $$

$$\leq O \left( H^5B_+^2|S||A|\log \frac{MH|S||A|}{\delta} + B_*M \right), $$

where the second inequality follows since every state-action pair becomes known after the number of visits is $\alpha H^3B_+^2|S||A|\log \frac{MH|S||A|}{\delta}$, and the last one by Lemma B.10.

**Lemma B.8** (Bound on Variance Term). *Conditioning on the good event, it holds that*

$$\sum_{m=1}^{M} \sum_{h=1}^{H} \frac{\text{Var}_{\mathcal{P}_k(s, a)}(J_m^u(s, a))}{\sqrt{h_{m-1}(s, a)}} \leq O \left( B_+^2|S||A|M\log(MH) + H^3B_+^2|S||A|\log \frac{MH|S||A|}{\delta} \right). $$
Proof. Applying Cauchy-Schwartz inequality we get

\[
\sum_{m=1}^{M} \sum_{h=1}^{H} \sqrt{\text{Var}_{P^{\top}}(J^{m}_{h+1})} \leq \sum_{m=1}^{M} \sum_{h=1}^{H} \sqrt{\text{Var}_{P^{\top}}(J^{m}_{h+1})} \cdot \mathbb{I}\{m^{m-1}(s_{h}^{m}, a_{h}^{m}) \geq H\} + 2H^{2} |\text{Alg}|
\]

\[
\leq \sum_{m=1}^{M} \sum_{h=1}^{H} \text{Var}_{P^{\top}}(J^{m}_{h+1}) \cdot \mathbb{I}\{m^{m-1}(s_{h}^{m}, a_{h}^{m}) \geq H\} + 2H^{2} |\text{Alg}|
\]

\[
\leq \sum_{m=1}^{M} \sum_{h=1}^{H} \text{Var}_{P^{\top}}(J^{m}_{h+1}) \cdot \mathbb{I}\{m^{m-1}(s_{h}^{m}, a_{h}^{m}) \geq H\} + 2H^{2} |\text{Alg}|
\]

(Lemma B.12)

\[
\leq \sum_{m=1}^{M} \mathbb{E} \left[ \sum_{h=1}^{H} \text{Var}_{P^{\top}}(J^{m}_{h+1}) \cdot \mathbb{I} \right] \mathbb{U}^{m} + 16H^{2} L_{M} \sqrt{3 |\text{Alg}| \log(MH)} + 2H^{2} |\text{Alg}|
\]

(Event $E_{\text{V}}^{\text{Var}}$ holds)

\[
\leq 3 \sum_{m=1}^{M} \mathbb{E} \left[ \sum_{h=1}^{H} \text{Var}_{P^{\top}}(J^{m}_{h+1}) \cdot \mathbb{I} \right] \mathbb{U}^{m} \sqrt{|\text{Alg}| \log(MH)}
\]

\[
+ 7 \sqrt{|\text{Alg}| H^{3} \log(MH)} + 2H^{2} |\text{Alg}|
\]

\[
\leq \sum_{m=1}^{M} \mathbb{E} \left[ \sum_{h=1}^{H} c(s_{h}^{m}, a_{h}^{m}) + c_{f}(s_{h+1}^{m}) - J^{m}_{h+1}(s_{h}) \right] \mathbb{U}^{m} \sqrt{|\text{Alg}| \log(MH)}
\]

\[
+ 7 \sqrt{|\text{Alg}| H^{3} \log(MH)} + 2H^{2} |\text{Alg}|
\]

(a) \[
\leq 3 \sum_{m=1}^{M} \mathbb{E} \left[ \sum_{h=1}^{H} c(s_{h}^{m}, a_{h}^{m}) + c_{f}(s_{h+1}^{m}) \right] \mathbb{U}^{m} \sqrt{|\text{Alg}| \log(MH)}
\]

\[
+ 7 \sqrt{|\text{Alg}| H^{3} \log(MH)} + 2H^{2} |\text{Alg}|
\]

(b) \[
\leq O \left( \sqrt{B_{*}^{2} |\text{Alg}| \log(MH)} + H^{3} B_{*}^{2} |\text{Alg}| \log \left( \frac{MH |\text{Alg}|}{\delta} \right) \right).
\]

where (a) is by law of total variance [Azar et al. 2017], see Lemma B.14 (b) is because the variance is bounded by the second moment, and the last inequality is by Lemma B.9.

\[\square\]

B.5 Bounds on the second moment

Lemma B.9. Conditioning on the good event, it holds that

\[
\sum_{m=1}^{M} \mathbb{E} \left[ \left( \sum_{h=1}^{H} c(s_{h}^{m}, a_{h}^{m}) + c_{f}(s_{h+1}^{m}) \right)^{2} \right] \mathbb{U}^{m} \leq O \left( B_{*}^{2} M + H^{*} B_{*}^{2} |\text{Alg}| \log \frac{MH |\text{Alg}|}{\delta} \right).
\]

28
Proof. Denote by \( h_m \) the last time step before reaching an unknown state-action pair (or \( H \) if it was not reached). By the event \( E_{\text{Sec1}} \) we have

\[
\sum_{m=1}^{M} \mathbb{E}\left[ \left( \sum_{i=1}^{H} c(s_i^{m}, a_i^{m}) + c_f(s_{H+1}^{m}) \right)^2 \left| \bar{U}^{m} \right. \right] \leq 2 \sum_{m=1}^{M} \left( \sum_{i=1}^{H} c(s_i^{m}, a_i^{m}) + c_f(s_{H+1}^{m}) \right)^2 + 62H^4L_M
\]

\[
\leq 4 \sum_{m=1}^{M} \left( \sum_{h=h_{m+1}}^{H} c(s_h^{m}, a_h^{m}) + c_f(s_{H+1}^{m})\mathbb{I}\{h_m \neq H\} \right)^2 + 62H^4L_M
\]

\[
+ 4 \sum_{m=1}^{M} \left( \sum_{h=1}^{h_m} c(s_h^{m}, a_h^{m}) + c_f(s_{H+1}^{m})\mathbb{I}\{h_m = H\} \right)^2
\]

\[
\leq 400\alpha H^6 B_*^2 |S|^2 |A| \log \left( \frac{|S||A|}{\delta} \right) + 4 \sum_{m=1}^{M} \sum_{h=1}^{h_m} c(s_h^{m}, a_h^{m}) + c_f(s_{H+1}^{m})\mathbb{I}\{h_m = H\} \right)^2 \left| \bar{U}^{m} \right]\]

where the third inequality follows since every state-action pair becomes known after the number of visits is \( \alpha H^4 B_*^2 |S|^2 |A| \log \left( \frac{|S||A|}{\delta} \right) \), the forth inequality by event \( E_{\text{Sec2}} \), and the last one by Lemma B.10.

\( \square \)

Lemma B.10. Let \( m \) be an episode and \( h_m \) be the last time step before an unknown state-action pair was reached (or \( H \) if they were not reached). Further, denote by \( C^m = \sum_{h=h}^{h_m} c(s_h^{m}, a_h^{m}) + c_f(s_{H+1}^{m})\mathbb{I}\{h_m = H\} \) the cumulative cost in the episode until time \( h_m \). Then, under the good event, \( \mathbb{E}[C^m \mid \bar{U}^m] \leq 3B_* \), and \( \mathbb{E}[(C^m)^2 \mid \bar{U}^m] \leq 2 \cdot 10^4 B_*^2 \).

Proof. Consider the following finite-horizon MDP \( M^m = (S \cup \{g\}, A, P^m, H, c^m, c_f^m) \) that contracts unknown state-action pairs with a new goal state, i.e., \( c^m(s, a) = c(s, a)\mathbb{I}\{s \neq g\} \) and \( c_f^m(s) = c_f(s)\mathbb{I}\{s \neq g\} \) and

\[
P^m_h(s' \mid s, a) = \begin{cases} 
0, & (s', \pi^m_{h+1}(s')) \text{ is unknown;} \\
P(s' \mid s, a), & s' \neq g \text{ and } (s', \pi^m_{h+1}(s')) \text{ is known;} \\
1 - \sum_{s'' \in S} P^m_h(s'' \mid s, a), & s' = g.
\end{cases}
\]

Denote by \( J^m \) the cost-to-go function of \( \pi^m \) in the MDP \( M^m \). Moreover, we slightly abuse notation to let \( \bar{P}^m \) be the transition function induced by \( \bar{P}^{m-1} \) in the MDP \( M^m \) similarly to \( P^m \), and \( \bar{J}^m \) the cost-to-go function of \( \pi^m \) with respect to \( \bar{P}^{m-1} \) (and cost function \( \bar{c}^m = \bar{c}^{m-1} - b_{c} - b_{p}^m \)). By the value
difference lemma (see, e.g., Shani et al., 2020), for every $s, h$ such that $(s, \pi^m_h(s))$ is known,

$$J^m_h(s) = \tilde{J}^m_h(s) + \sum_{h' = h}^H \mathbb{E} \left[ c^m(s_{h'}, a_{h'}) - \tilde{c}^m_h(s_{h'}, a_{h'}) \mid s_h = s, P^m, \pi^m \right]$$

$$+ \sum_{h' = h}^H \mathbb{E} \left[ \left( P^m_h(s) \cdot \mid s_{h'}, a_{h'} \right) - \tilde{P}^m_h(s) \cdot \mid s_{h'}, a_{h'} \right) \cdot \tilde{J}^m \mid s_h = s, P^m, \pi^m$$

$$\leq \tilde{J}^m_h(s) + H \max_{(s, \pi^m_h(s))\in\text{known}} \text{lc}(s, \pi^m_h(s)) - \tilde{c}^m_h(s, \pi^m_h(s)) + H \left\| \tilde{J}^m \right\|_1 \max_{(s, \pi^m_h(s))\in\text{known}} \| P^m(s, \pi^m_h(s)) - \tilde{P}^m_h(s, \pi^m_h(s)) \|_1$$

$$\leq \tilde{J}^m_h(s) + H \max_{(s, \pi^m_h(s))\in\text{known}} \text{lc}(s, \pi^m_h(s)) - \tilde{c}^m_h(s, \pi^m_h(s)) + 2HB \max_{(s, \pi^m_h(s))\in\text{known}} \| P^m(s, \pi^m_h(s)) - \tilde{P}^m_h(s, \pi^m_h(s)) \|_1,$$

where the last inequality follows by optimism and since $J^m_1(s) \leq B_*$. Thus, by Appendix B.2 (since all state-action pairs in $\tilde{M}^m$ are known), we have that $J^m_h(s) \leq J^m_1(s) + 2B_* \leq 3B_*$. Notice that $C^m$ is exactly the cost in the MDP $\tilde{M}^m$, so $\mathbb{E}[C^m | \bar{U}^m] \leq 3B_*$. Similarly, we notice that $\mathbb{E}[(C^m)^2 | \bar{U}^m] = \mathbb{E}[(\bar{C})^2]$, where $\bar{C}$ is the cumulative cost in $\tilde{M}^m$, and we override notation by denoting $\bar{C} = \sum_{h=1}^H c(s_h, a_h) + c_f(s_{H+1})$. We split the time steps into $Q$ blocks as follows. We denote by $t_1$ the first time step in which we accumulated a total cost of at least $3B_*$ (or $H + 1$ if it did not occur), by $t_2$ the first time step in which we accumulated a total cost of at least $3B_*$ after $t_1$, and so on up until $t_Q = H + 1$. Then, the first block consists of time steps $t_0 = 1, \ldots, t_1 - 1$, the second block consists of time steps $t_1, \ldots, t_2 - 1$, and so on. Since $J^m_h(s) \leq 3B_*$ we must have $c(s_h, a_h) \leq 3B_*$ for all $h = 1, \ldots, H$ and thus in every such block the total cost is between $3B_*$ and $6B_*$. Thus,

$$\mathbb{E} \left[ \left( \sum_{h=1}^H c(s_h, a_h) + c_f(s_{H+1}) \right)^2 \right] \geq \mathbb{E} \left[ \left( \sum_{h=1}^H c(s_h, a_h) + c_f(s_{H+1}) \right)^2 \right]$$

$$\geq \mathbb{E} \left[ \left( \sum_{h=1}^{t_{i+1}-1} c(s_h, a_h) + c_f(s_{H+1}) \right)^2 \right]$$

by Jensen’s inequality. On the other hand,

$$\mathbb{E} \left[ \left( \sum_{h=1}^H c(s_h, a_h) + c_f(s_{H+1}) \right)^2 \right] = \mathbb{E} \left[ \left( \sum_{h=1}^H c(s_h, a_h) + c_f(s_{H+1}) - J^m_1(s_1) \right)^2 \right]$$

$$\leq 2\mathbb{E} \left[ \left( \sum_{h=1}^H c(s_h, a_h) + c_f(s_{H+1}) - J^m_1(s_1) \right)^2 \right] + 2J^m_1(s_1)^2$$

$$\leq 2\mathbb{E} \left[ \left( \sum_{h=t_{i-1}}^{t_{i+1}-1} c(s_h, a_h) - J^m_1(s_i) + J^m_1(s_{t_{i-1}}) \right)^2 \right] + 18B_*^2$$

$$\leq 4\mathbb{E} \left[ \left( \sum_{h=t_{i-1}}^{t_{i+1}-1} c(s_h, a_h) - J^m_1(s_i) + J^m_1(s_{t_{i-1}}) \right)^2 \right] + 18B_*^2$$

For (a) we used the fact that $\mathbb{E} \left[ \sum_{h=t_{i-1}}^{t_{i+1}-1} c(s_h, a_h) - J^m_1(s_i) + J^m_1(s_{t_{i-1}}) \right] = 0$ using the Bellman optimality equations and conditioned on all past randomness up until time $t_i$, and the fact that $t_{i+1}$ is a stopping
Thus, we have
\[ \mathbb{E} \left[ \sum_{t=1}^{t+1} c(s_t, a_t) - J_{h}^*(s_t) + J_{h+1}^m(s_{t+1}) \right] = \mathbb{E} \left[ \sum_{t=1}^{t+1} c(s_t, a_t) - J_{h}^*(s_t) + J_{h+1}^m(s_{t+1}) \right] \\
= \mathbb{E} \left[ \sum_{t=1}^{t+1} \mathbb{E} \left[ c(s_t, a_t) - J_{h}^*(s_t) + J_{h+1}^m(s_{t+1}) | s_h \right] \right] \\
= \mathbb{E} \left[ \sum_{t=1}^{t+1} c(s_t, a_t) + \mathbb{E} \left[ J_{h+1}^m(s_{t+1}) | s_h \right] - J_{h}^*(s_h) \right] = 0. \]

Thus, we have
\[ 9B_r^2 \mathbb{E}[Q]^2 \leq 324B_r^2 \mathbb{E}[Q] + 18B_r^2, \]
and solving for \( \mathbb{E}[Q] \) we obtain \( \mathbb{E}[Q] \leq 37 \), so
\[ \mathbb{E}[\mathbb{E}[Q]] \leq 2 \cdot 10^4 B_r^2. \]

**Lemma B.11** (Variance Difference is Upper Bounded by Value Difference). Assume that the value at time step \( h + 1 \) is optimistic, i.e., \( J_{h+1}^m(s) \leq J_{h+1}^*(s) \) for all \( s \in S \). Conditioning on the event \( \cap_m \mathbb{P}^m (s) \) it holds for all \( (s, a) \in S \times A \) that
\[ \sqrt{2L_m} \left| \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^m) - \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^*) \right| \leq \frac{1}{\alpha} \mathbb{E} \left[ \left( J_{h+1}^m(s') - J_{h+1}^*(s') \right) \right] + \frac{(5 + \alpha/2)B_r L_m}{n^{m-1}(s, a) \vee 1}, \]
for any \( \alpha > 0 \).

**Proof.** Conditioning on \( \cap_m \mathbb{P}^m (s) \), the following relations hold.
\[ \sqrt{2L_m} \left| \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^m) - \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^*) \right| \leq \sqrt{2L_m} \left| \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^m) - \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^*) \right| \\
+ \frac{12B_r^2 L_m}{n^{m-1}(s, a) \vee 1} \]
\[ \leq \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^m - J_{h+1}^*) + \frac{12B_r^2 L_m}{n^{m-1}(s, a) \vee 1} \]
\[ \leq \mathbb{E} \left[ \left( J_{h+1}^m(s') - J_{h+1}^*(s') \right)^2 \right] + \frac{12B_r^2 L_m}{n^{m-1}(s, a) \vee 1}. \]
where the second inequality is by Lemma [5.3] and the last relation holds since \( J_{h+1}^m(s'), J_{h+1}^*(s') \in [0, B_r] \) (the first, by model assumption, and the second, by the update rule) and since \( J_{h+1}^m(s') \geq J_{h+1}^*(s') \) by the assumption the value is optimistic. Thus,
\[ \sqrt{2L_m} \left| \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^m) - \sqrt{\text{Var} \mathbb{P}^m(s, a)} (J_{h+1}^*) \right| \leq \mathbb{E} \left[ \left( J_{h+1}^m(s') - J_{h+1}^*(s') \right)^2 \right] \left( \frac{2B_r L_m}{n^{m-1}(s, a) \vee 1} \right) \\
+ \frac{\sqrt{24B_r L_m} \left| (J_{h+1}^m(s') - J_{h+1}^*(s')) \right|}{n^{m-1}(s, a) \vee 1} \]
\[ \leq \frac{1}{\alpha} \mathbb{E} \left[ \left( J_{h+1}^m(s') - J_{h+1}^*(s') \right)^2 \right] + \frac{(5 + \alpha/2)B_r L_m}{n^{m-1}(s, a) \vee 1}, \]
where the last inequality is by Young’s inequality, \( ab \leq \frac{1}{\alpha} a^2 + \frac{\alpha}{2} b^2 \).

B.6 Useful results for reinforcement learning analysis

Lemma B.12 (Cumulative Visitation Bound for Stationary MDP, e.g., Efroni et al., 2020, Lemma 23). It holds that

$$\sum_{m=1}^{M} \sum_{s,a} \mathbb{I}\{n^{m-1}(s,a) \geq H\} \frac{\sum_{h=1}^{H} \mathbb{I}\{s_{b}^{m} = s, a_{b}^{m} = a\}}{n^{m-1}(s,a) \lor 1} \leq 3 \text{SilAl log}(MH).$$

Proof. Recall that we recompute the optimistic policy only in the end of episodes in which the number of visits to some state-action pair was doubled. In this proof we refer to a sequence of consecutive episodes in which we did not perform a recomputation of the optimistic policy by the name of epoch. Let $E$ be the number of epochs and note that $E \leq \text{SilAl log}(MH)$ because the number of visits to each state-action pair $(s,a)$ can be doubled at most log$(MH)$ times. Next, denote by $\tilde{n}^e(s,a)$ the number of visits to $(s,a)$ until the end of epoch $e$ and by $\tilde{N}^e(s,a)$ the number of visits to $(s,a)$ during epoch $e$. The following relations hold for any fixed $(s,a)$ pair.

$$\sum_{m=1}^{M} \mathbb{I}\{n^{m-1}(s,a) \geq H\} \frac{\sum_{h=1}^{H} \mathbb{I}\{s_{b}^{m} = s, a_{b}^{m} = a\}}{n^{m-1}(s,a) \lor 1} =$$

$$= \sum_{e=1}^{E} \mathbb{I}\{\tilde{n}^{e-1}(s,a) \geq H\} \frac{\tilde{N}^{e}(s,a)}{\tilde{n}^{e-1}(s,a)}$$

$$= \sum_{e=1}^{E} \mathbb{I}\{\tilde{n}^{e-1}(s,a) \geq H\} \frac{\tilde{N}^{e}(s,a)}{\tilde{n}^{e}(s,a)}$$

$$\leq 3 \sum_{e=1}^{E} \mathbb{I}\{\tilde{n}^{e-1}(s,a) \geq H\} \frac{\tilde{N}^{e}(s,a)}{\tilde{n}^{e}(s,a)}$$

where the first inequality follows since $\frac{\tilde{N}^{e}(s,a)}{\tilde{n}^{e-1}(s,a)} < \frac{2 \tilde{n}^{e-1}(s,a) + H}{\tilde{n}^{e-1}(s,a)} \leq 3$ for $\tilde{n}^{e-1}(s,a) \geq H$, and the second inequality follows by the inequality $\frac{a}{b} \leq \log \frac{a}{b}$ for $a \geq b > 0$. Applying Jensen’s inequality we conclude the proof:

$$\sum_{m=1}^{M} \sum_{s,a} \mathbb{I}\{n^{m-1}(s,a) \geq H\} \frac{\sum_{h=1}^{H} \mathbb{I}\{s_{b}^{m} = s, a_{b}^{m} = a\}}{n^{m-1}(s,a) \lor 1} \leq 3 \sum_{s,a} \log (\tilde{n}^{H}(s,a) \lor 1)$$

$$\leq 3 \text{SilAl log} \left( \sum_{s,a} \tilde{n}^{H}(s,a) \right)$$

$$\leq 3 \text{SilAl log}(MH).$$

Lemma B.13 (Transition Difference to Next State Expectation, Efroni et al., 2021, Lemma 28). Let $Y \in \mathbb{R}_+$ be a vector such that $0 \leq Y(s) \leq 2H$ for all $s \in S$. Let $P_1$ and $P_2$ be two transition models and $n \in \mathbb{R}_+$. Let $\Delta P(\cdot|s,a) \in \mathbb{R}_+$ and $\Delta P(s'|s,a) = P_1(s'|s,a) - P_2(s'|s,a)$. Assume that

$$\forall (s,a,s') \in S \times A \times S, h \in [H] : |\Delta P(s'|s,a)| \leq \sqrt{\frac{C_1 L_m P_1(s'|s,a)}{n(s,a) \lor 1}} + \frac{C_2 L_m}{n(s,a) \lor 1}.$$
for some $C_1, C_2 > 0$. Then, for any $\alpha > 0$.

$$|\Delta P(\cdot | s, a) \cdot Y| \leq \frac{1}{\alpha} \mathbb{E}_{P(\cdot | s, a)}[Y(s')] + \frac{HLm(2C_2 + \alpha |S|C_1/2)}{n(s, a) \vee 1}.$$ 

Lemma B.14 (Law of Total Variance, e.g., Azar et al., 2017). For any $\pi$ the following holds.

$$\mathbb{E}\left[\sum_{h=1}^{H} \text{Var}_{P(\cdot | s_h, a_h)}(J_{h+1}) \mid \pi\right] = \mathbb{E}\left[\left(\sum_{h=1}^{H} c(s_h, a_h) + c_f(s_{H+1}) - J_1^*(s_1)\right)^2 \mid \pi\right].$$
C Extending the reduction to unknown $B_*$

In this section we assume $B_* \geq 1$ to simplify presentation, but the results work similarly for $B_* < 1$. To handle unknown $B_*$, we leverage techniques from the adversarial SSP literature [Rosenberg and Mansour 2020, Chen and Lu 2021] for learning the diameter of an SSP problem. Recall that the SSP-diameter $D$ [Tarbouriech et al., 2020] is defined as $D = \max_{s \in S} \min_{\pi, s' \rightarrow A} T^\pi(s)$. So to compute $D$ we can find the optimal policy with respect to the constant cost function $c_1(s, a) = 1$, and compute its cost-to-go function. Rosenberg and Mansour [2020] utilize this observation to estimate the SSP-diameter. They show that one can estimate the expected time from a state $s$ to the goal state $g$ by running the Bernstein-SSP algorithm of Rosenberg et al. [2020] with unit costs for $L = \tilde{O}(D^2|S||A|)$ episodes and setting the estimator to be the average cost per episode times 10.

Inspired by their approach, we use the Bernstein-SSP algorithm on the actual costs, in order to estimate the expected cost of the optimal policy. Although Bernstein-SSP suffers from suboptimal regret, we run it only for a small number of episodes and therefore we will only suffer from slightly larger additive factors in our regret bound, but keep minimax optimal regret for large enough $K$.

By similar proofs to Lemmas 26 and 27 from Rosenberg and Mansour [2020, Appendix J], we can show that the cost-to-go from state $s$ can be estimated up to a constant multiplicative factor by running Bernstein-SSP for $L = \tilde{O}(T^s_2|S||A|)$ episodes. This is demonstrated in the following lemma, where the upper bound follows from the regret guarantees of Bernstein-SSP and the lower bound follows from concentration arguments (and noticing that the regret is minimized by playing the optimal policy, but even then it is not zero).

**Lemma C.1.** Let $s \in S$ and $L \geq 2400T^s_2|S||A| \log^3 \frac{KT_*|S||A|}{\delta}$. Run Bernstein-SSP with initial state $s$ for $L$ episodes and denote by $\bar{B}_s$ the average cost per episode times 10. Then, with probability $1 - \delta$,

$$J^\pi(s) \leq \bar{B}_s \leq O(B_*)$$

Thus, we use the first $L$ visits to each state in order to estimate its cost-to-go. A state which was visited at least $L$ times will be called $B_*$-known, and otherwise $B_*$-unknown (not to be confused with our previous definition of known state-action pair). To that end, we split the total time steps into $E$ epochs. In epoch $e$, we apply our reduction to a virtual MDP $M^e$ that is identical to $M$ in $B_*$-known states, but turns $B_*$-unknown states into zero-cost sinks (like the goal state). For every state $s \in S$ we maintain a Bernstein-SSP algorithm $B_s$. Every time we reach a $B_*$-unknown state $s$, we run an episode of $B_s$ until the goal is reached.

Note that in the virtual MDP $M^e$ we can compute an upper bound on the optimal cost-to-go using our estimates. Epoch $e$ ends once some $B_*$-unknown state $s$ is visited $L$ times and thus becomes $B_*$-known. Therefore the number of epochs $E$ is bounded by $|S|$. The important change, introduced by Chen and Lu [2021], is to not completely initialize our finite-horizon algorithm $A$ in the beginning of a new epoch as this leads to an extra $|S|$ factor in the regret. Instead, algorithm $A$ inherits the experience (i.e., visit counters and accumulated costs) of the previous epoch in $B_*$-known states.

The reduction without knowledge of $B_*$ is presented in Algorithm 4 and next we prove that it maintains the same regret bound up to a slightly larger additive factor.

**Theorem C.2.** Let $A$ be an admissible algorithm for regret minimization in finite-horizon MDPs and denote its regret in $M$ episodes by $\hat{R}_A(M)$. Then, running Algorithm 2 with $A$ ensures that, with probability at least $1 - 2\delta$,

$$R_K \leq \hat{R}_A \left( 4K + 4 \cdot 10^5|S||A|\omega_A \log \frac{KT_*|S||A|\omega_A}{\delta} + 4 \cdot 10^4T^s_2|S||A| \log^3 \frac{KT_*|S||A|}{\delta} \right)$$

$$+ O \left( B_* \sqrt{K \log \frac{KT_*|S||A|\omega_A}{\delta} + T_*|S||A|\log^2 \frac{KT_*|S||A|\omega_A}{\delta} + T^s_2|S||A| \log^4 \frac{KT_*|S||A|}{\delta} } \right),$$

where $\omega_A$ is a quantity that depends on the algorithm $A$ and on $|S|, |A|, H$.

Using the reduction with the ULCV1 algorithm, we can again obtain optimal regret for SSP.
Theorem C.3. Running the reduction in Algorithm 7 with the finite-horizon regret minimization algorithm ULCV1 ensures, with probability at least $1 - \delta$,

$$R_K = O \left( B_\ast \sqrt{S|A|K \log \frac{KT_s |S| |A|}{\delta} + T_s^4 |S| |A| \log^4 \frac{KT_s |S| |A|}{\delta} + T_s^4 |S| |A| \log^4 \frac{KT_s |S| |A|}{\delta} \right).$$

Algorithm 4 REDUCTION FROM SSP TO FINITE-HORIZON MDP WITH UNKNOWN $B_\ast$.

1: input: state space $S$, action space $A$, initial state $s_{init}$, goal state $g$, confidence parameter $\delta$, number of episodes $K$, bound on the expected time of the optimal policy $T_\ast$, and algorithm $\mathcal{A}$ for regret minimization in finite-horizon MDPs.
2: initialize a Bernstein-SSP algorithm $B_\ast$ with initial state $s$ and confidence parameter $\delta/|S|$ for every $s \in S$.
3: set $L = 10^4 T_\ast^2 |S| |A| \log^4 \frac{KT_s |S| |A|}{\delta}$, $S_{\text{known}} = \{s_{\text{init}}\}$ and $N_f(s) = L \| s = s_{\text{init}} \|$ for every $s \in S$.
4: run $B_{\text{init}}$ for $L$ episodes and set $B_{\text{init}}$ to be the average cost per episode times 10.
5: initialize $\mathcal{A}$ with state space $\tilde{S} = S \cup \{g\}$, action space $A$, horizon $H = 8T_\ast \log(8K)$, confidence parameter $\frac{\delta}{|S|}$, terminal costs $\tilde{c}_f(s) = 8\| s = s_{\text{init}} \| \tilde{B}_{\text{init}}$ and bound on the expected cost of the optimal policy $9\tilde{B}_{\text{init}}$.
6: initialize intervals counter $m \leftarrow 0$, time steps counter $t \leftarrow 1$ and epochs counter $e \leftarrow 1$.
7: for $k = L + 1, \ldots, K$ do
8: set $s_t \leftarrow s_{\text{init}}$.
9: while $s_t \neq g$ do
10: set $m \leftarrow m + 1$, feed initial state $s_t$ to $\mathcal{A}$ and obtain policy $\pi^m = \Pi_{h=1}^m \tilde{S} \rightarrow A$.
11: for $h = 1, \ldots, H$ do
12: play action $a_t = \pi^m(s_t)$, suffer cost $C^s_t = c(s_t, a_t)$, and set $s_{t+1} = s_t, a_{t+1} = a_t, C^s_{t+1} = C^s_t$.
13: observe next state $s_{t+1} \sim P(\cdot \mid s_t, a_t)$ and set $t \leftarrow t + 1$.
14: if $s_{t} = g$ or $s_t \notin S_{\text{known}}$, then pad trajectory to be of length $H$ and BREAK.
15: end if
16: end for
17: set $s_{t+1} = s_t$.
18: feed trajectory $U^m = (s_1^m, a_1^m, \ldots, s_t^m, a_t^m, s_{t+1}^m)$ and costs $\{C^s_h\}_{h=1}^{H}$ to $\mathcal{A}$.
19: if $s_t \notin S_{\text{known}}$ then
20: set $N_f(s_t) \leftarrow N_f(s_t) + 1$ and run an episode of $B_{s_t}$.
21: if $N_f(s_t) = L$ then
22: set $e \leftarrow e + 1$ and $S_{\text{known}} \leftarrow S_{\text{known}} \cup \{s_t\}$.
23: set $B_{s_t}$ to be the average cost per episode of $B_{s_t}$ times 10.
24: reinitialize $\mathcal{A}$ by updating the terminal costs as $\tilde{c}_f(s) = 8\| s \in S_{\text{known}} \| \max_{s \in S_{\text{known}}} \tilde{B}_{s_t}$, updating the bound on the expected cost of the optimal policy $9\max_{s \in S_{\text{known}}} \tilde{B}_{s_t}$ and deleting the history of $\mathcal{A}$ only in state $s_t$.
25: end if
26: end if
27: end if
28: end while
29: end for

C.1 Proof of Theorem C.2.

We follow the analysis of the known $B_\ast$ case under the event that Lemma C.1 holds for all states (which happens with probability at least $1 - \delta$), i.e., $\tilde{r}^{\pi}(s) \leq \tilde{B}_s \leq O(B_s)$ for every $s \in S$. We start by decomposing the regret similarly to Lemma 11. Note that now there is an additional term that comes from the regret of the Bernstein-SSP algorithms that are used to estimate $B_\ast$.

Lemma C.4. For $H = 8T_\ast \log(8K)$, we have the following bound on the regret of Algorithm 7

$$R_K \leq \tilde{R}_{\mathcal{A}}(M) + \sum_{m=1}^{M} \left( \sum_{\forall h \geq 1} C^s_{h} + \hat{c}_f(s_{h+1}^m) - \hat{J}_1^\pi(s_{h}^m) \right) + O \left( T_\ast^2 |S| |A| \log^4 \frac{KT \ast |S| |A|}{\delta} \right),$$

where $M$ is the total number of intervals.
Remark 6. Note that now each interval is considered in the context of the current epoch, i.e., the current $B_*$-known states. The finite-horizon cost-to-go $J^∗_m$ is with respect to the MDP of $B_*$-known states. Moreover, for interval $m$ that ends in a $B_*$-unknown state, the last state in the trajectory $s_{H+1}^m$ will be a $B_*$-unknown state and the length of the interval may be shorter than $H$ (just like intervals that end in the goal state).

Proof. Every interval ends either in the goal state, in a $B_*$-known state or in a $B_*$-unknown state. The first two cases are similar to the proof of Lemma 4.1 because our estimates $B_\ell$ in all $B_*$-known states $s$ are upper bounds on $J^∗_m(s)$. Importantly, we do not initialize $\mathcal{A}$ in the end of an epoch and this allows us to get its regret bound without an extra $|s|$ factor. The reason is that $\mathcal{A}$ is an admissible (and thus optimistic) algorithm, so it operates based on the observations it collected. Another important note is that the cost in the virtual MDP $M_r$ is always bounded by the cost in the actual MDP $M$.

We now focus on the last case. Recall that if interval $m$ ends in a $B_*$-unknown state $s$, then the terminal cost is 0 and we run an episode of the Bernstein-SSP algorithm $B_*$. Thus, the excess cost of running Bernstein-SSP algorithms is bounded by $|s|$ times the Bernstein-SSP regret plus $|s|B_*L$, i.e., we can bound it as follows

$$|s|B_*L + O(B_*^2|s|^2\sqrt{|s|L\log \frac{KT_*|s||s|A}{\delta}} + T_*^2|s|^3|s|A\log^2 \frac{KT_*|s||s|A}{\delta}).$$

To finish the proof we plug in the definition of $L$. \hfill \square

Next, we bound the number of intervals. Again, we get a similar bound to Lemma 4.3 but with an additional term for all the intervals that ended in a $B_*$-unknown state (there are at most $|s|$ such intervals).

Lemma C.5. Assume that the reduction is performed using an admissible algorithm $\mathcal{A}$. Then, with probability at least $1 - \frac{3\delta}{8},$

$$M \leq 4 \left( K + \frac{10^4|s||s|A \log}{\delta} \frac{KT_*|s||s|A}{\delta} + \frac{10^4T_*^2|s|^3|s|A\log^2 \frac{KT_*|s||s|A}{\delta}}{\delta} \right).$$

Proof. The proof is based on the claim that in every interval there is a probability of at least 1/2 that the agent reaches either the goal state, an unknown state-action pair or a $B_*$-unknown state. This is proved similarly to Lemma A.3 since we can look at the MDP of $B_*$-known states, and then the claim of Lemma A.3 is equivalent to reaching either the goal state, an unknown state-action pair or a $B_*$-unknown state.

With this claim the proof follows easily by following the proof of Lemma 4.3. We simply define $X^m$ to be 1 if an unknown state-action pair or the goal or a $B_*$-unknown state were reached during interval $m$ (and 0 otherwise). Then, we have

$$\sum_{m=1}^{M} X^m \leq K + |s||s|A \log \frac{MH|s|A}{\delta} + |s|, \|

which implies the Lemma following the same argument based on Freedman’s inequality. \hfill \square

Finally, we bound the deviation of the actual cost in each interval from its expected value. The proof is exactly the same as Lemma 4.2. The second moment of the accumulated cost until reaching the goal, an unknown state-action pair or a $B_*$-unknown state is of order $B^2_*\ell$, and therefore in almost all intervals (except for a finite number) the accumulated cost will be of order $B_\ell$ with high probability (in other intervals the cost is trivially bounded by $H + O(B_\ell))$.

Lemma C.6. Assume that the reduction is performed using an admissible algorithm $\mathcal{A}$. Then, the following holds with probability at least $1 - \frac{3\delta}{8},$

$$\sum_{m=1}^{M} \sum_{\ell=1}^{H} C^m_{\ell} + \hat{\gamma}(s_{H+1}^m) - \hat{J}^∗_m(s_{H+1}^m) = O \left( B_*\sqrt{\frac{M \log}{\delta} (H + B_\ell|s||s|A \log \frac{MT_*|s||s|A}{\delta})} \right) + O \left( (H + B_\ell)T_*^2|s|^3|s|A\log^3 \frac{KT_*|s||s|A}{\delta} \right).$$

The proof of the theorem is finished by combining Lemmas C.4 to C.6 together with the guarantees of the admissible algorithm $\mathcal{A}$ and Lemma C.1, similarly to Theorem 5.1.
**D Lower bound**

In this section we prove Theorem 2.3 which lower bounds the expected regret of any learning algorithm for the case $B_* < 1$. It complements the lower bound found in [Rosenberg et al., 2020] for the case $B_* \geq 1$.

By Yao’s minimax principle, in order to derive a lower bound on the learner’s regret, it suffices to show a distribution over MDP instances that forces any deterministic learner to suffer a regret of $\Omega(\sqrt{B_* N \log K})$ in expectation.

To construct this distribution, we follow [Rosenberg et al., 2020] with a few modifications. We initially consider the simpler setting with two states: an initial state and the goal state. We now embed a hard MAB instance into our problem where the optimal action has an expected cost of $B_*$. To that end, consider a distribution over MDPs where a special action $a^\star$ is chosen a-priori uniformly at random. Then, all actions lead to the goal state $g$ with probability 1. The cost $C_k(s_{\text{init}}, a^\star)$ chosen at episode $k$ is 1 w.p. $B_*$ and 0 otherwise. The cost of any other action $a \neq a^\star$ is 1 w.p. $B_* + \epsilon$ and 0 otherwise, where $\epsilon \in (0, 1/8)$ is a constant to be determined. Thus the optimal policy will always play $a^\star$ and we have $J^\star(s_{\text{init}}) = B_*$.

Fix any deterministic learning algorithm, we shall now quantify the regret of the learner in terms of the number of times that it plays $a^\star$. Indeed, we have that the optimal cost is $B_*$, and the learner loses $\epsilon$ in the regret each time she plays an action other than $a^\star$. Therefore, $\mathbb{E}[R_k] \geq \epsilon \cdot (K - \mathbb{E}[N])$, where $N$ is the number of times $a^\star$ was chosen in $s_{\text{init}}$.

We now introduce an additional distribution of the costs which denote by $\mathbb{P}_\text{unif}$. $\mathbb{P}_\text{unif}$ is identical to the distribution over the costs defined above, and denoted by $\mathbb{P}$, except that $\mathbb{P}[C_k(s_{\text{init}}, a) = 1] = B_* + \epsilon$ for all actions $a \in A$ regardless of the choice of $a^\star$. We denote expectations over $\mathbb{P}_\text{unif}$ by $\mathbb{E}_\text{unif}$, and expectations over $\mathbb{P}$ by $\mathbb{E}$. The following lemma uses standard lower bound techniques used for multi-armed bandits (see, e.g., Faksh et al., 2010, Theorem 13) to bound the difference in the expectation of $N$ when the learner plays in $\mathbb{P}$ compared to when it plays in $\mathbb{P}_\text{unif}$.

**Lemma D.1.** Suppose that $B_* \leq \frac{1}{2}$. Denote by $\mathbb{P}_\text{unif,a}$, $\mathbb{E}_\text{unif,a}$, $\mathbb{P}_a$, $\mathbb{E}_a$ the distributions and expectations defined above conditioned on $a^\star = a$. For any deterministic learner we have that $\mathbb{E}_a[N] \leq \mathbb{E}_{\text{unif,a}}[N] + \epsilon K \sqrt{\mathbb{E}_{\text{unif,a}}[N]/B_*}$.

**Proof.** Fix any deterministic learner. Let us denote by $C^{(k)}$ the sequence of costs observed by the learner up to episode $k$ and including. Now, as $N \leq K$ and the fact that $N$ is a deterministic function of $C^{(K)}$, $\mathbb{E}_a[N] \leq \mathbb{E}_{\text{unif,a}}[N] + K \cdot \text{TV}(\mathbb{P}_{\text{unif,a}}[C^{(K)}], \mathbb{P}[C^{(K)}])$, and Pinsker’s inequality yields

$$\text{TV}(\mathbb{P}_{\text{unif,a}}[C^{(K)}], \mathbb{P}[C^{(K)}]) \leq \sqrt{\frac{1}{2} \mathbb{K}L(\mathbb{P}_{\text{unif,a}}[C^{(K)}] \| \mathbb{P}_a[C^{(K)}])},$$

Next, the chain rule of the KL divergence obtains

$$\mathbb{K}L(\mathbb{P}_{\text{unif,a}}[C^{(K)}] \| \mathbb{P}_a[C^{(K)}]) = \sum_{k=1}^K \sum_{C^{(k)}} \mathbb{P}_{\text{unif,a}}[C^{(k)}] \cdot \mathbb{K}L(\mathbb{P}_{\text{unif,a}}[C_k(s_{\text{init}}, a_k) \mid C^{(k)}] \| \mathbb{P}_a[C_k(s_{\text{init}}, a_k) \mid C^{(k)}]),$$

where $a_k$ is the action chosen by the learner at episode $k$. (Recall that after which the model transition to the goal state and the episode ends.)

Observe that at any episode, since the learning algorithm is deterministic, the learner chooses an action given $C^{(k)}$ regardless of whether $C^{(k)}$ was generated under $\mathbb{P}$ or under $\mathbb{P}_{\text{unif,a}}$. Thus, the $\mathbb{K}L(\mathbb{P}_{\text{unif,a}}[C_k(s_{\text{init}}, a_k) \mid C^{(k)}] \| \mathbb{P}_a[C_k(s_{\text{init}}, a_k) \mid C^{(k)}])$ is zero if $a_k \neq a_\star$, and otherwise

$$\mathbb{K}L(\mathbb{P}_{\text{unif,a}}[C_k(s_{\text{init}}, a_k) \mid C^{(k)}] \| \mathbb{P}_a[C_k(s_{\text{init}}, a_k) \mid C^{(k)}]) = (B_* + \epsilon) \log \left(1 + \frac{\epsilon}{B_*}\right) + (1 - B_* - \epsilon) \log \left(1 - \frac{\epsilon}{1 - B_*}\right) \leq \frac{\epsilon^2}{B_*(1 - B_*)},$$

37
where we used that \( \log(1 + x) \leq x \) for all \( x > -1 \), and since we assume \( B_* \leq \frac{1}{2} \) and \( \epsilon < \frac{1}{\sqrt{2}} \) that imply \( -\epsilon(1 - B_*) \geq -\frac{1}{3} > -1 \). Plugging the above back into Eq. (15) and using \( B_* \leq \frac{1}{2} \) gives the lemma.

In the following result, we combine the lemma above with standard techniques from lower bounds of multi-armed bandits (see Auer et al., 2002 for example).

**Theorem D.2.** Suppose that \( B_* \leq \frac{1}{2}, \epsilon \in (0, \frac{1}{2}) \) and \(|A| \geq 2\). For the problem described above we have that

\[
\mathbb{E}[R_K] \geq \epsilon K \left( \frac{1}{2} - \epsilon \sqrt{\frac{K}{|A|B_*}} \right).
\]

**Proof of Theorem D.2.** Note that as under \( \mathcal{P}_{\text{unif}} \) the cost distributions of all actions are identical. Denote by \( N_a \) the number of times that the learner chooses action \( a \) in \( s_{\text{init}} \). Therefore,

\[
\sum_{a \in A} \mathbb{E}_{\text{unif}, a}[N] = \sum_{a \in A} \mathbb{E}_{\text{unif}}[N_a] = \mathbb{E}_{\text{unif}} \left[ \sum_{a \in A} N_a \right] = K. \tag{16}
\]

Recall that \( a^* \) is sampled uniformly at random before the game starts. Then,

\[
\mathbb{E}[R_K] = \frac{1}{|A|} \sum_{a \in A} \mathbb{E}_{a}[R_K]
\]

\[
\geq K - \frac{1}{|A|} \sum_{a \in A} \mathbb{E}_{a}[N]
\]

\[
\geq K - \frac{1}{|A|} \sum_{a \in A} \left( \mathbb{E}_{\text{unif}, a}[N] + \epsilon K \sqrt{\mathbb{E}_{\text{unif}, a}[N]/B_*} \right) \tag{Lemma D.1}
\]

\[
\geq K - \frac{1}{|A|} \sum_{a \in A} \mathbb{E}_{\text{unif}, a}[N] + \epsilon K \sqrt{\frac{1}{|A|B_*} \sum \mathbb{E}_{\text{unif}, a}[N]} \tag{Jensen’s inequality}
\]

\[
= K - \frac{K}{|A|} + \epsilon K \sqrt{\frac{K}{|A|B_*}}. \tag{Eq. (16)}
\]

The theorem follows from \(|A| \geq 2\) and by rearranging.

**Proof of Theorem 2.3.** Consider the following MDP. Let \( S \) be the set of states disregarding \( g \). The initial state is sampled uniformly at random from \( S \). Each \( s \in S \) has its own special action \( a^*_s \). All actions transition to the goal state with probability 1. The cost \( C_k(s, a) \) of action \( a \neq a^*_s \) in episode \( k \) and state \( s \) is 1 with probability \( B_* + \epsilon \) and 0 otherwise. The cost of \( C_k(s, a^*_s) \) is 1 with probability \( B_* \) and 0 otherwise. Note that for each \( s \in S \), the learner is faced with a simple problem as the one described above from which it cannot learn about from other states \( s' \neq s \). Therefore, we can apply Theorem D.2 for each \( s \in S \) separately and lower bound the learner’s expected regret the sum of the regrets suffered at each \( s \in S \), which would depend on the number of times \( s \in S \) is drawn as the initial state. Since the states are chosen uniformly at random there are many states (constant fraction) that are chosen \( \Theta(K/|S|) \) times. Summing the regret bounds of Theorem D.2 over only these states and choosing \( \epsilon \) appropriately gives the sought-after bound.

Denote by \( K_s \) the number of episodes that start in each state \( s \in S \).

\[
\mathbb{E}[R_k] \geq \sum_{s \in S} \mathbb{E} \left[ \epsilon K_s \left( \frac{1}{2} - \epsilon \sqrt{\frac{K_s}{|A|B_*}} \right) \right] = \frac{\epsilon K}{2} - \epsilon^2 \sqrt{\frac{K}{|A|B_*}} \sum_{s \in S} \mathbb{E}[K_s^{3/2}]. \tag{17}
\]

Applying Cauchy-Schwartz inequality gives

\[
\sum_{s \in S} \mathbb{E}[K_s^{3/2}] \leq \sum_{s \in S} \sqrt{\mathbb{E}[K_s]} \sqrt{\mathbb{E}[K_s^2]} = \sum_{s \in S} \sqrt{\mathbb{E}[K_s]} \sqrt{\mathbb{E}[K_s^2] + \text{Var}[K_s]}
\]

\[
= \sum_{s \in S} \sqrt{\frac{K}{|S|}} \sqrt{\frac{K^2}{|S|^2} + \frac{K}{|S|} (1 - \frac{1}{|S|})} \leq K \sqrt{\frac{2K}{|S|^2}}.
\]
where we have used the expectation and variance formulas of the Binomial distribution. The lower bound is now given by applying the inequality above in Eq. (17) and choosing $\epsilon = \frac{1}{\sqrt{B \cdot \text{var} / K}}$. □
E General useful results

**Lemma E.1** (Freedman’s Inequality). Let \( \{X_i\}_{i \geq 1} \) be a real valued martingale difference sequence adapted to a filtration \( \{F_t\}_{t \geq 0} \). If \( |X_i| \leq R \) a.s. then for any \( \eta \in (0, 1/R) \), \( T \in \mathbb{N} \) it holds with probability at least \( 1 - \delta \),

\[
\sum_{t=1}^{T} X_t \leq \eta \sum_{t=1}^{T} E[X_t^2|F_{t-1}] + \frac{\log(1/\delta)}{\eta}.
\]

**Lemma E.2** (Consequences of Freedman’s Inequality for Bounded and Positive Sequence of Random Variables, e.g., Efroni et al., 2021, Lemma 27). Let \( \{Y_i\}_{i \geq 1} \) be a real valued sequence of random variables adapted to a filtration \( \{F_t\}_{t \geq 0} \). Assume that for all \( t \geq 1 \) it holds that \( 0 \leq Y_t \leq C \) a.s., and \( T \in \mathbb{N} \). Then, each of the following inequalities hold with probability at least \( 1 - \delta \).

\[
\sum_{t=1}^{T} E[Y_t|F_{t-1}] \leq \left(1 + \frac{1}{2C}\right) \sum_{t=1}^{T} Y_t + 2(2C + 1)^2 \log \frac{1}{\delta}
\]
\[
\sum_{t=1}^{T} Y_t \leq 2 \sum_{t=1}^{T} E[Y_t|F_{t-1}] + 4C \log \frac{1}{\delta}.
\]

**Lemma E.3** (Standard Deviation Difference, e.g., Zanette and Brunskill, 2019). Let \( V_1, V_2 : S \to \mathbb{R} \) be fixed mappings. Let \( P(s) \) be a probability measure over the state space. Then, \( \sqrt{\text{Var}(V_1) - \text{Var}(V_2)} \leq \sqrt{\text{Var}(V_1 - V_2)} \).
