Abstract

In this paper we investigate supersymmetric effects to the threshold production cross section of top quark pairs in electron positron annihilation. In particular, we consider the complete one-loop corrections from the strong and weak sector of the Minimal Supersymmetric Standard Model.

1 Introduction

One of the main goals of a future electron positron collider is the precise measurement of the top quark production cross section in the threshold region. The comparison to the theoretical prediction allows for a precise extraction of the top quark mass, its width, the strong coupling and — in case the Higgs boson is not too heavy — the top quark Yukawa coupling.

The next-to-next-to-leading order (NNLO) QCD corrections to the total cross section \( \sigma(e^+e^- \to t\bar{t}) \) has been completed several years ago [1]. One observes large perturbative corrections from the second order terms which make a precise prediction difficult. In the recent years a big effort has been undertaken to complete the third-order corrections to \( \sigma(e^+e^- \to t\bar{t}) \) [2–12]. First numerical estimates [13] indicate that the convergence of the perturbation theory is improved after the inclusion of the NNNLO terms. In addition to the third-order corrections also the resummation of the NNLL terms is studied [14–16].

In order to profit from precise experimental measurements it is desired to reach an uncertainty below approximately 3% from the theory side [17]. Radiative corrections
of this order can easily be reached by effects from theories beyond the Standard Model (SM). In this paper we consider the effect of supersymmetric corrections within the Minimal Supersymmetric Standard Model (MSSM). Furthermore we confirm the results from Refs. [18–20] and [21] obtained in the framework of the SM and two-Higgs-doublet model (THDM) of type II, respectively.

It is convenient to perform the calculation of the production cross section in the framework of an effective theory where the produced top quarks are described by a non-relativistic two-particle Green’s function. All effects connected to energy scales above \( \mu \approx m_W \) are contained in coefficient functions which represent the new couplings in the effective Lagrangian. Since the masses of the supersymmetric particles are above the electroweak scale they only influence the matching coefficients of the effective operators. For the top quark production we have to consider the vector current in the full and effective theory which constitutes a building block for all threshold phenomena involving the coupling of the initial electron and positron via photon, \( Z \) boson or box diagrams to heavy quarks.

The remainder of the paper is organized as follows: In the next Section we provide the formulae which are necessary for the evaluation of the threshold cross section. Afterwards we discuss in Sections 3 and 4 the numerical effects from the strong and weak sector of the MSSM and present in Section 5 our conclusions.

2 Framework

Non-relativistic QCD (NRQCD) allows for a consistent separation of the hard corrections connected to energy scales of the order of the weak gauge bosons or higher from the soft scales which are involved in the top anti-top boundstate. Within NRQCD we can normalize the production cross section to \( \sigma(e^+e^- \rightarrow \mu^+\mu^-) = (4\pi\alpha^2)/(3s) \) and denote the ratio by \( R \)

\[
R \left( e_L^+e_R^- \rightarrow t\bar{t}X \right) = \frac{8\pi}{s} \text{Im} \left[ (h_{R,V})^2 H_V + (h_{R,A})^2 H_A \right],
\]

where \( s \) is the square of the center-of-mass energy. In Eq. (1) left-handed positrons and right-handed electrons are considered; for \( e_R^+e_L^- \) in the initial state a similar expression is obtained by replacing R by L in Eq. (1). Note that the initial states \( e_R^+e_R^- \) and \( e_L^+e_L^- \) are suppressed by a factor \( (m_e/M_W)^2 \sim 10^{-10} \) and are thus negligible. \( h_{R,V} \) and \( h_{R,A} \) are so-called helicity amplitudes which absorb the matching coefficients representing the coupling of the effective operators. They take care of the hard part of the reaction. The first subscript of \( h \) refers to helicity of the electron, and the second one to the vector \( (J_V^\mu = \bar{\psi}\gamma^\mu\psi) \) or axial-vector coupling \( (J_A^\mu = \bar{\psi}\gamma^\mu\gamma_5\psi) \) of the gauge bosons to the top quark current. In this paper we evaluate corrections to \( h_{R,V} \) and \( h_{L,V} \).

The bound-state dynamics is contained in the so-called hadronic part formed by current-current correlators within NRQCD. They are denoted by \( H_V \) and \( H_A \) in Eq. (1) and will not be considered further in this paper. At threshold the contribution from

```
the axial-vector current is suppressed by two powers of top quark velocity thus we only consider the vector current $J_V^{\mu}$ in this work. Its counterpart in the effective theory reads $j_V^i = \psi^\dagger \sigma^i \chi$.

It is convenient to separate the photon and $Z$ contribution in $h_{I,V}^{\text{tree}}$ and write

$$h_{I,V}^{\text{tree}} = h_{I,V}^{\gamma,\text{tree}} + h_{I,V}^{Z,\text{tree}}.$$  (2)

Here the tree-level contributions are given by ($I = L/R$)

$$h_{I,V}^{\gamma,\text{tree}} = Q_e Q_t,$$
$$h_{I,V}^{Z,\text{tree}} = \frac{s \beta^f \beta_V^t}{s - M_Z^2},$$
$$\beta^t_V = \frac{\beta^t_R + \beta^t_L}{2},$$
$$\beta^f_I = \frac{(T_3)^f_I - s_w^2 Q_f}{s_w c_w},$$  (3)

where the $\beta^f_I$ is the coupling of a fermion ($f = e, t$) to the $Z$ boson, $s_w$ is the sine of the weak mixing angle ($c_w^2 = 1 - s_w^2 = m_W^2/m_Z^2$), and electric and iso-spin charges for top quark and electron are given by

$$Q_e = -1, \; Q_t = 2/3, \; (T_3)^{t_L} = 1/2, \; (T_3)^{e_L} = -1/2, \; (T_3)^{f_R} \equiv 0.$$  (4)

In the following the abbreviation $T_3^f \equiv (T_3)^{f_L}$ will be used. Let us note that $h_{I,A}$ can be obtained by substituting $\beta^f_V$ by $\beta^A = (\beta^R - \beta^L)/2$ in formula (3). The loop corrections are taken into account via

$$h_{I,V} = h_{I,V}^{\text{tree}} + h_{I,V}^X,$$  (5)

where $X$ stands for QCD, SQCD (supersymmetric QCD), SM, THDM$^1$ or MSSM. The numerical effects are discussed for the quantity

$$\Delta^X = \frac{\delta R^X}{R^{LO}} = \frac{2 h_{L,V}^{\text{tree}} \text{Re}(h_{L,V}^X) + 2 h_{R,V}^{\text{tree}} \text{Re}(h_{R,V}^X)}{(h_{L,V}^{\text{tree}})^2 + (h_{R,V}^{\text{tree}})^2},$$  (6)

where the sum over all helicity states of the incoming electron and positron has been performed. Let us note that in our case for the evaluation of $h_{I,V}$ one has to set $s = 4m_t^2$. Furthermore the external top quarks are on their mass shell. In addition we are only interested in hard corrections resulting from the real matching condition. Corrections to the cross section stemming from imaginary part of the matching coefficient, which takes into account the finite lifetime of the top quark, are discussed for SM in Ref. [22].

$^1$In this paper we use the THDM type II where $u/d$-type quarks couple to different Higgs doublets $H_u/H_d$. Note that the Higgs sector of the MSSM corresponds to the Higgs sector of THDM type II.
Figure 1: QCD and SQCD diagrams. (a): Gluon contribution at the $t\bar{t}\gamma/Z$-vertex. (b): Gluon contribution to the top-quark selfenergy. (c): Gluino contribution at the $t\bar{t}\gamma/Z$-vertex. (d): Gluino contribution to the top quark selfenergy.

For the generation of the Feynman diagrams we use the Mathematica program FeynArts [23]. The amplitudes are further processed with the help of the programs FormCalc [24] and FeynCalc [25] which take the traces, map the occurring integrals to a standard basis and reduce the tensor integrals to a minimal set of scalar integrals usually denoted by $A_0$, $B_0$ and $C_0$. Since we have a quite particular momentum configuration it is not possible to use the above mentioned packages as black boxes but apply some modifications. In fact, the choice $s = 4m_t^2$ allows for a partial fractioning in the denominators of the loop integrands appearing in $t\bar{t}\gamma/Z$-vertex and box diagrams which effectively reduces the number of external legs by one. Consider, e.g., the integrand of a generic three-point function (omitting the $i\epsilon$ prescription)

$$
\frac{1}{(p^2 + 2q_1p - M_1^2 + m_t^2)(p^2 - 2q_2p - M_2^2 + m_t^2)(p^2 - M_3^2)},
$$

where $p$ is the integration momentum and $q_1^2 = q_2^2 = m_t^2$ are the squared momenta of the top quarks. After choosing $q_1 = q_2 = q/2$ and applying a partial fractioning one arrives at

$$
\frac{2}{M_t^2 + M_2^2 - M_3^2 - m_t^2} \left( \frac{1}{p^2 - M_1^2 + m_t^2} - \frac{1}{p^2 - M_3^2} \right) \times \left( \frac{1}{p^2 + q \cdot p - M_2^2 + m_t^2} + \frac{1}{p^2 - q \cdot p - M_2^2 + m_t^2} \right).
$$

As a consequence the result can be expressed in terms of only two-point functions. In a similar way one can express the box diagrams in terms of three-point functions.

3 Supersymmetric QCD

In this Section we consider the effects from Supersymmetric QCD (SQCD) to the top quark threshold production. There are only four contributing Feynman diagrams which are shown in Fig. [1]. The one-loop QCD corrections are known since long [26] and the corresponding matching coefficient is defined via the relation

$$
J_{\nu}^i = J_{\nu}^{i(1)} =\left(1 + c_v^{(1)} \right) j_{\nu}^i = \left(1 - 2C_F \frac{\alpha_s}{\pi} \right) j_{\nu}^i.
$$
This effect can be incorporated in the helicity amplitude by a simple rescaling of the tree-level contributions

\[ h_{I,V}^{\text{QCD}} = h_{I,V}^{\gamma,\text{tree}} a_g^\gamma + h_{I,V}^{Z,\text{tree}} a_g^Z. \]  

(10)

Using the explicit expressions for \( h_{I,V}^{\text{tree}} \), one can already see that the contribution of \( a_g^Z \) to the relative correction \( \Delta X \) of the cross section is in general suppressed by factor 0.08 compared to the one resulting from contribution of \( a_g^\gamma \). For the QCD the coefficients \( a_g^{\gamma/Z} \) read

\[ a_g^{\gamma/Z} = c_v^{(1)}. \]  

(11)

Since we work in a supersymmetric framework we repeated the calculation of \( c_v^{(1)} \) within dimensional reduction [27]. Although both the one-loop vertex corrections and the result for the wave function counterterm are different from their counter parts in dimensional regularization we observe that the result given in Eq. (9) does not change. This is expected since at tree-level the strong coupling constant is absent.

The SQCD corrections can also be cast in the form of Eq. (10)

\[ h_{I,V}^{\text{SQCD}} = h_{I,V}^{\gamma,\text{tree}} a_{\tilde{g}}^\gamma + h_{I,V}^{Z,\text{tree}} a_{\tilde{g}}^Z, \]  

(12)

with

\[ a_{\tilde{g}}^\gamma = \Gamma_{V,\tilde{g}} + \delta Z_{V,\tilde{g}}^t, \]

\[ a_{\tilde{g}}^Z = \Gamma_{Z,\tilde{g}} + \delta Z_{V,\tilde{g}}^t - \frac{3}{8s_w^2 - 3} \delta Z_{A,\tilde{g}}, \]  

(13)

where \( \Gamma_{V,\tilde{g}} \) represents the gluino contribution to the vector part of the one-loop vertex normalized by the corresponding tree level coupling. The wave function renormalization constant \( Z_{V,\tilde{g}}^{t/A,\tilde{g}} = 1 + \delta Z_{V,\tilde{g}}^{t/A,\tilde{g}} \) is defined in the on-shell scheme and renders the \( \gamma t\tilde{t} \) and \( Zt\tilde{t} \) vertex finite. The definition of both counter terms can be found in Appendix A, where they are expressed in terms of vector- (\( V \)) and axial-vector part (\( A \)) of the top quark selfenergy. The subscript \( \tilde{g} \) reminds that only the diagrams involving a gluino are considered in each expression. Since the results are quite compact we present the analytical formulae for the individual contributions of the right-hand side of Eq. (13).
The contributions to the wave function counterterm reads

\[
\delta Z_{V,\tilde{g}}' = \sum_{s=1}^{2} \frac{\alpha_s}{6\pi m_{\tilde{t}_s}^2} \left\{ -2m_{\tilde{t}_s}^2 \left[ -2m_{\tilde{g}}m_{\tilde{t}_s} (\Omega_{s1s} + \Omega_{s2s1}) \right] \right.
\]

\[
+ (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2) (\Omega_{s1s} + \Omega_{s2s2}) \right] B'_0 \left( m_{\tilde{t}_s}^2, m_{\tilde{g}}, m_{\tilde{t}_s}^2 \right)
\]

\[
+ (\Omega_{s1s1} + \Omega_{s2s2}) \left[ A_0 (m_{\tilde{t}_s}^2) - A_0 (m_{\tilde{g}}^2) \right] 
\]

\[
+ (m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2 - m_{\tilde{t}_s}^2) (\Omega_{s1s1} + \Omega_{s2s2}) \right] B_0 \left( m_{\tilde{t}_s}^2, m_{\tilde{g}}, m_{\tilde{t}_s}^2 \right) \biggr\},
\]

\[
\delta Z_{A,\tilde{g}}' = \sum_{s=1}^{2} \frac{\alpha_s}{6\pi m_{\tilde{t}_s}^2} (\Omega_{s1s1} - \Omega_{s2s2}) \left\{ A_0 (m_{\tilde{t}_s}^2) - A_0 (m_{\tilde{g}}^2) \right. 
\]

\[
- (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2) B_0 \left( m_{\tilde{t}_s}^2, m_{\tilde{g}}, m_{\tilde{t}_s}^2 \right) \biggr\},
\]

and the vertex corrections are given by

\[
\Gamma_{V,\tilde{g}}^\gamma = \sum_{s=1}^{2} \frac{\alpha_s (\Omega_{s1s1} + \Omega_{s2s2})}{9\pi m_{\tilde{t}_s}^2 (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2)} \left\{ 2m_{\tilde{t}_s}^2 (m_{\tilde{t}_s}^2 - m_{\tilde{t}_s}^2) B_0 \left( 4m_{\tilde{t}_s}^2, m_{\tilde{t}_s}^2, m_{\tilde{t}_s}^2 \right) \right. 
\]

\[
+ \frac{1}{2} (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2) \left[ A_0 (m_{\tilde{t}_s}^2) - A_0 (m_{\tilde{g}}^2) + 2m_{\tilde{t}_s}^2 \right] 
\]

\[
- \frac{1}{2} \left[ m_{\tilde{t}_s}^4 - 2 (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2) m_{\tilde{t}_s}^2 + (m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2)^2 \right] B_0 \left( m_{\tilde{t}_s}^2, m_{\tilde{g}}, m_{\tilde{t}_s}^2 \right) \biggr\},
\]

\[
\Gamma_{V,\tilde{g}}^Z = \sum_{s,v=1}^{2} \frac{\alpha_s [4s_{uv}^2 (\Omega_{s1s1} + \Omega_{s2s2}) - 3\Omega_{s1s1} (\Omega_{s1s1} + \Omega_{s2s2})]}{9\pi m_{\tilde{t}_s}^2 (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2 - 2m_{\tilde{g}}^2 - 2m_{\tilde{t}_s}^2) (8s_{uw}^2 - 3)} 
\]

\[
\times \left[ \left\{ + \left[ m_{\tilde{t}_s}^4 - 2 (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2) m_{\tilde{t}_s}^2 + (m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2)^2 \right] B_0 \left( m_{\tilde{t}_s}^2, m_{\tilde{g}}, m_{\tilde{t}_s}^2 \right) 
\]

\[
+ \left[ m_{\tilde{t}_s}^2 + m_{\tilde{u}}^2 - 2 (m_{\tilde{t}_s}^2 + m_{\tilde{g}}^2) \right] \right. 
\]

\[
\times \left[ A_0 (m_{\tilde{t}_s}^2) - A_0 (m_{\tilde{g}}^2) + 2m_{\tilde{t}_s}^2 \right] 
\]

\[
\left. \left[ (1 + B_0 \left( 4m_{\tilde{t}_s}^2, m_{\tilde{t}_s}^2, m_{\tilde{t}_u}^2 \right)) \right] \right. 
\]

\[
+ \left[ m_{\tilde{t}_s}^2 (m_{\tilde{t}_s}^2 + m_{\tilde{u}}^2 + 2 (m_{\tilde{g}}^2 - m_{\tilde{t}_s}^2)) - \frac{1}{4} (m_{\tilde{t}_s}^2 - m_{\tilde{u}}^2)^2 \right] 
\]

\[
\times \left. \left[ B_0 \left( m_{\tilde{t}_s}^2, m_{\tilde{t}_s}^2, \frac{1}{2} m_{\tilde{t}_s}^2 + \frac{1}{2} m_{\tilde{t}_s}^2 - m_{\tilde{t}_s}^2 \right) \right. \biggr\} \right. 
\]

\[
\biggr\} + \left\{ s \leftrightarrow u \right. \biggr\}. \quad (15)
\]

In Eqs. (14) and (15) we introduced the abbreviations $\Omega_{ijkl} = U_{ij}U^*_{kl}$ where $U_{ij}$ are the elements of the top squark mixing matrix (cf. Appendix B). The conventions for the functions $A_0$ and $B_0$ are adapted from Ref. [24,28] where explicit results can be found. Further $B'_0$ is the defined as derivative of $B_0$ with respect to the first argument. Our
analytic formulae are in agreement with Ref. [29] where the result has been expressed in terms of a one-dimensional integral assuming a real mixing matrix for the top squarks.

It is instructive to consider the limit where all SUSY particles have a common mass $m_{\text{SUSY}}$. In this limit the above formulae are simplified significantly. In particular, the result becomes independent of the matrix elements $U_{ij}$ and $\delta Z'_{A\tilde{t}} = 0$. We furthermore have $a_{\tilde{g}} = a_{\gamma} = a_{\tilde{g}}^T$ which reads

$$a_{\tilde{g}}(m_{\text{SUSY}}^2) = \frac{4\alpha_s}{9m_t^2\pi}\left\{\frac{1}{2}m_t^2 - \frac{3}{2}m_t^4B'_0(m_t^2, m_{\text{SUSY}}^2, m_{\text{SUSY}}^2) + (m_{\text{SUSY}}^2 - m_t^2) [B_0(m_t^2, m_{\text{SUSY}}^2, m_{\text{SUSY}}^2) - B_0(4m_t^2, m_{\text{SUSY}}^2, m_{\text{SUSY}}^2)]\right\}$$

$$= \frac{\alpha_s}{45\pi}\left\{y^2 + \frac{16}{21}y^3 + \frac{1}{2}y^4 + \frac{76}{231}y^5 + O(y^6)\right\}.$$  

(16)

After the second equal sign we have expanded the result in terms of $y = m_t^2/m_{\text{SUSY}}^2$.

Let us in the following discuss the numerical effects of the one-loop QCD and SQCD corrections. For $m_t = 173.1$ GeV and $\alpha_s^{(6)}(m_t) = 0.108$ the QCD corrections amount to $\Delta^{\text{QCD}} = 18.3\%$ (corresponding to $\alpha_s^{(5)}(m_Z) = 0.1176$) and thus constitute the largest contribution.

In the simplified scenario described by Eq. (16) one obtains the SQCD corrections as shown in Fig. 2. From the figure one can see that for $m_{\text{SUSY}} > 200$ GeV the expansion agrees well with the exact result showing a relative deviation below 10%. For all $m_{\text{SUSY}} > m_t$ the relative correction to the threshold cross section stays below 0.6%. The size of the SQCD corrections in a non-universal SUSY mass scenario is shown in Fig. 3 where $\Delta^{\text{SQCD}}$ is plotted as a function of $m_{\tilde{t}_2}$ and $m_{\tilde{g}}$ for $m_{\tilde{t}_1} = m_t$. Since our results are $\pi$-periodic in $\theta_{\tilde{t}}$ we have chosen for illustration the four values $\theta_{\tilde{t}} \in \{0, \frac{\pi}{4}, \frac{\pi}{2}, \frac{3\pi}{4}\}$. The figures show, that only for light masses of the second top squark ($m_{\tilde{t}_2} \lesssim 2m_t$) $\Delta^{\text{SQCD}}$ can have a strong dependence on $m_{\tilde{t}_2}$.

In general one observes corrections below 1% which become negligible for large masses of the SUSY particles. A correction factor above 1% is only observed for $\theta_{\tilde{t}} = \pi/4$ and relatively light gluino masses of the order of the top quark mass which are excluded within the MSSM [30].

4 Electroweak corrections in the THDM and the MSSM

QCD corrections only affect the $\gamma t\bar{t}/Zt\bar{t}$ vertex. On the other hand, electroweak corrections require also the inclusion of the $e^+e^-\gamma/e^+e^-Z$ vertex and furthermore of gauge boson self energy and box contributions which are necessary in order to arrive at a finite and gauge parameter independent result. Typical Feynman diagrams contributing to the individual building blocks are shown in Fig. 4 for the SM and in Fig. 5 for the MSSM. Due to the renormalization procedure (we follow Ref. [31,32]) also $W$ boson and fermion
self-energy contributions have to be computed which are also shown in Figs. 4 and 5. They are used in order to render the four building blocks individually finite which is quite convenient to deal with.

In a first step we have used our set-up in order to compute the SM contribution. We find complete agreement with Refs. [18, 19, 21]. Afterwards the THDM model has been considered and the results from Ref. [20] have been reproduced. Let us note that for vanishing bottom quark mass the corrections in the THDM model can easily be obtained from the analytical results for Higgs- and Goldstone boson contribution calculated in the SM by adjusting the coupling factors and boson masses in the loop diagrams.

Results for the MSSM are not yet available in the literature. However, it is possible to compare our results for the vector boson selfenergies with Ref. [33] where the top quark production has been considered above the threshold. As far as the box contribution is concerned, new kind of diagrams occur in the MSSM where the electron and positron in the initial state are not part of the same fermion line (and similarly for the top quarks in the final state), cf. Fig. 5(a). Due to the different tensor structure, originating from the Majorana character of charginos and neutralinos, it is not straightforward to process these contributions with our set-up. On the other hand, it is possible to extract the relative correction to the cross section at the threshold by taking the limit $s \to 4m_t^2$ since these diagrams only involve heavy particles inside the loop. However, due to the numerical properties of the loop functions [24] the limit can not be taken naively. Instead we evaluate the result of Ref. [33] for the box contribution above threshold and extrapolate to $s = 4m_t^2$.

\[ \Delta^{\text{SQCD}} = 2a_\beta \] computed from Eq. (16) as a function of $m_{\text{SUSY}}$. The solid line represents the exact result and the dashed curve the expansion including terms up to order $\left( \frac{m_t^2}{m_{\text{SUSY}}^2} \right)^5$. 

\[ \frac{\Delta^{\text{SQCD}}}{m_{\text{SUSY}}} \text{ vs. } m_{\text{SUSY}} (\text{GeV}) \]

---

2In Ref. [20] the expression for $a_{ZH}^2$ is proportional to $\cos(\beta - \alpha)$ which should be replaced by $\sin(\beta - \alpha)$. 

---

8
Figure 3: $\Delta^{\text{SQCD}}$ as a function of $m_{\tilde{t}_2}$ and $m_{\tilde{g}}$ (normalized to the top quark mass) for $m_{\tilde{t}_1} = m_t$ and different values of the mixing angle $\theta_{\tilde{t}}$.

In this way we obtain the threshold contribution for the new box diagrams with three significant digits which is sufficient for the phenomenological analysis. We have applied the same procedure for the SM box contributions which provides both a cross check on our analytical calculation and the very procedure for extracting the threshold contribution.

Due to the occurrence of many different masses and mixing angles the remaining general expression is quite lengthy in the case of the MSSM. Thus, in the following we will only discuss the numerical effects. In Ref. [34] a package is provided which allows the numerical evaluation of the corrections described in this paper. It uses Mathematica as
front-end and calls Fortran for the time-consuming parts of the calculation. In addition an interface to SPheno [35] is provided, which generates numerical values for the masses and mixing angles on the basis of a certain SUSY breaking scenario.

In the numerical discussion we will restrict ourselves to the SUSY breaking scenario based on minimal supergravity (mSUGRA) and use the Snowmass Points and Slopes (SPS) [36, 37] in order get an impression of size of the corrections. In addition to the five mSUGRA parameters $m_0$, $m_{1/2}$, tan $\beta$, $A_0$ and sgn($\mu$) (cf. Tab.1) which serve as input for the spectrum generator we use the following input values for the remaining SM
Table 1: Input values for the SPS scenarios as defined in references [36, 37]. All masses are given in GeV and \( \text{sgn}(\mu) = 1 \).

| Points  | Slopes                  |
|---------|-------------------------|
| Label   | \( m_0 \) | \( m_{1/2} \) | \( A_0 \) | \( \tan \beta \) | \( m_0 \) | \( A_0 \) |
| SPS1a   | 70     | 250       | -300   | 10       | -       | -       |
| SPS1a   | 100    | 250       | -100   | 10       | 0, 4\( m_{1/2} \) | -0, 4\( m_{1/2} \) |
| SPS1b   | 200    | -400      | 0      | 30       | -       | -       |
| SPS2    | 1450   | 300       | 0      | 10       | 2\( m_{1/2} + 850 \) | 0       |
| SPS3    | 90     | 400       | 0      | 10       | 0, 25\( m_{1/2} - 10 \) | 0       |
| SPS4    | 400    | 300       | 0      | 50       | -       | -       |
| SPS5    | 150    | 300       | -1000  | 5        | -       | -       |

Table 2: Numerical values for \( \Delta X^{\text{EW}} \) \( X \in \{ \text{SM, THDM, MSSM} \} \) for various SPS scenarios.

| Parameters | SPS1a | SPS1a' | SPS1b | SPS2 | SPS3 | SPS4 | SPS5 |
|------------|-------|--------|-------|------|------|------|------|
| \( \Delta^{\text{SM EW}} \)         | 0.152 | 0.151  | 0.149 | 0.149| 0.150| 0.149|      |

\begin{align}
    m_W &= 80.40 \text{GeV}, & m_Z &= 91.1876 \text{GeV}, & c_w^2 &= m_W^2/m_Z^2, \\
    m_t &= 173.1 \text{GeV}, & m_b &= 4.2 \text{GeV}, & \alpha^{-1} &= 137.036, \\
    \Delta\alpha_{\text{had}}(m_Z) &= 277.45 \times 10^{-4}, & \Delta\alpha_{\text{lep}}(m_Z) &= 314.97 \times 10^{-4}. 
\end{align}

In a first step our Mathematica program transfers the input values to the spectrum generator SPheno [35] which produces numerical values for all unknown MSSM parameters relevant for our analysis. The output is automatically imported into Mathematica and afterwards used in order to evaluate the THDM or MSSM corrections. More details about the functionality of our package is provided via the usual Mathematica internal documentation and example files which in addition automatically generate the plots and tables shown in this paper.

The numerical impact of the corrections in different mSUGRA scenarios can be seen in Tab. 2 where \( \Delta^{\text{SM EW}}, \Delta^{\text{THDM EW}} \) and \( \Delta^{\text{MSSM EW}} \) are evaluated for several SPS points. Note that \( \Delta^{\text{SM EW}} \) varies since the SM Higgs boson is identified with the lightest MSSM Higgs boson.

\footnote{Following Ref. [41] we replace light fermion contributions to the derivative of the photon vacuum polarization function by \( \Delta\alpha_{\text{had}}^{(5)}(m_Z) \) and \( \Delta\alpha_{\text{lep}}(m_Z) \).}

\footnote{We add EW to the superscript in order to make clear that only electroweak and no strong corrections are considered.}
The SM corrections amount to a sizeable shift of about 15% which get reduced by roughly 5% to 6% in the case of the THDM. The main reason for this reduction is the smaller coupling of the top quark to the light Higgs boson. At the same time only numerically small contributions arise from the diagrams involving heavy Higgs bosons. In Tab. 2 one observes only a marginal difference between the THDM and the MSSM. It is thus instructive to have a closer look at the dependence on \( m_{1/2} \) as suggested by the SPS scenarios. For illustration we show in Fig. 6 the comparison of \( \Delta^{\text{SM EW}} \), \( \Delta^{\text{THDM EW}} \) and \( \Delta^{\text{MSSM EW}} \) for SPS1 and SPS2. In both cases we observe only small corrections beyond the THDM, i.e. from the neutralino and chargino sector of the MSSM. Larger deviations of the order of 0.5% are only observed for those values of \( m_{1/2} \) where the corresponding chargino masses are close to the top quark mass. This becomes clear in Fig. 7 where we show the correction of the finite building blocks separately for the case of SPS1a. One can see a relatively strong variation in the dashed curve which shows the contributions from the charginos. It is interesting to note that the peak around \( m_{1/2} \approx 150 \text{GeV} \) in \( \Delta_{\text{Box}} \) is clearly visible in Fig. 6(a) whereas a cancelation among the various parts occurs for the peak close to \( m_{1/2} \approx 250 \text{GeV} \). For comparison we plot in Fig. 7(d) the contribution from SQCD (dashed-dotted). For \( m_{1/2} \gtrsim 150 \text{GeV} \) it is smaller than the chargino contribution. Corrections above 0.5% are only reached for relatively small values of \( m_{1/2} \) which corresponds to small values of the gluino mass.

Let us finally mention that we performed our calculation in the THDM and MSSM for finite bottom quark mass and investigated possible large corrections for higher values of \( \tan \beta \). However, even for the mSUGRA scenario SPS4 where \( \tan \beta = 50 \), the result for massless bottom quark is \( \Delta_{m_b=0}^{\text{MSSM EW}} = 0.099 \), thus the effect of finite bottom quark mass adds 0.002 to \( \Delta_{m_b=0}^{\text{MSSM EW}} \) (see Tab. 2).

5 Conclusions

In this paper we investigated the complete weak and strong one-loop corrections within the MSSM to the threshold production of top-quark pairs at a future \( e^+e^- \) linear collider. For the SM, THDM, QCD and SQCD corrections we confirmed the results in the literature, the genuine supersymmetric electroweak corrections are new.

As far as the numerical importance is concerned, the electroweak SM corrections amount up to +15% for light Higgs masses. After extending the Higgs sector we observe for the SPS scenarios a screening of about −5% to −6% in the THDM (type II). The pure supersymmetric corrections from the chargino, neutralino and the strong sector are below 1% in most of the parameter space.

Acknowledgements

We would like to thank Christian Schappacher for sharing his program and knowledge about FormCalc, Thomas Hahn for his support, and J.H. Kühn for valuable discussions. This work was supported by the DFG through SFB/TR 9 and BMBF O5HT4VK4VKA13.
A On-shell counterterms

In this appendix we discuss the definition of the counterterms appearing in Eq. (13). In order to define the fermionic on-shell counterterms one needs the coefficient functions of the tensor decomposition from the corresponding fermion selfenergy:

\[ \Sigma(q, m) = m \Sigma_s(q^2, m) + \not{q} \Sigma_v(q^2, m) + \not{q} \gamma^5 \Sigma_a(q^2, m). \] (18)

They can be extracted with the help of the following projections:

\[ \Sigma_s(q^2, m) = \frac{1}{4m} tr \{ \Sigma(q, m) \}, \] (19a)

\[ \Sigma_v(q^2, m) = \frac{1}{4q^2} tr \{ \not{q} \Sigma(q, m) \}, \] (19b)

\[ \Sigma_a(q^2, m) = \frac{1}{4q^2} tr \{ \gamma^5 \not{q} \Sigma(q, m) \}. \] (19c)

The wave function counterterms are then given by

\[ \delta Z_f^V = -\Sigma_v(m_f^2, m_f) - 2m_f^2 \frac{\partial}{\partial q^2} \left[ \Sigma_v(q^2, m_f) + \Sigma_s(q^2, m_f) \right] \bigg|_{q^2=m_f^2}, \] (20)

\[ \delta Z_A^f = \Sigma_a(m_f^2, m_f). \] (21)

B Mixing matrices

Let us for definiteness provide in this Appendix the definition of the mixing matrix \( U_f = (U_{ij}) \) used in Eq. (14) and (15). We work with flavor diagonal sfermion mixings, where the left and right handed sfermion fields \( \tilde{f}_L \) and \( \tilde{f}_R \) are connected to the mass eigenstates \( \tilde{f}_1 \) and \( \tilde{f}_2 \) via

\[ \left( \begin{array}{c} \tilde{f}_1' \\ \tilde{f}_2' \end{array} \right) = U_f \left( \begin{array}{c} \tilde{f}_L \\ \tilde{f}_R \end{array} \right). \] (22)

The 2 \times 2 mixing matrix \( U_f \) diagonalizes the mass matrix of the corresponding sfermion \( \tilde{f} \):

\[ U_f m_f^2 U_f^\dagger = \left( \begin{array}{cc} m_{f_1}^2 & 0 \\ 0 & m_{f_2}^2 \end{array} \right). \] (23)

In the case where the mass matrix \( m_f^2 \) contains only real entries, one can choose \( U_f \) to be orthogonal. For its parameterization only one angle \( \theta_f \) is needed and the transformation from mass to gauge eigenstates can be written as follows:

\[ \tilde{f}_1 = \tilde{f}_L \cos \theta_f + \tilde{f}_R \sin \theta_f, \]

\[ \tilde{f}_2 = \tilde{f}_L \cos \theta_f - \tilde{f}_R \sin \theta_f. \] (24)
