MUKAI’S PROGRAM FOR NON-PRIMITIVE CURVES ON K3 SURFACES

YIRAN CHENG, ZHIYUAN LI, AND HAOYU WU

Abstract. Mukai’s program in [15] seeks to recover a K3 surface $X$ from any curve $C$ on it by exhibiting it as a Fourier–Mukai partner to a Brill–Noether locus of vector bundles on the curve. In the case $X$ has Picard number one and the curve $C \in |H|$ is primitive, this was confirmed by Feyzbakhsh in [11, 12] for $g \geq 11$ and $g \neq 12$. More recently, Feyzbakhsh has shown in [10] that certain moduli spaces of stable bundles on $X$ are isomorphic to the Brill–Noether locus of curves in $|H|$ if $g$ is sufficiently large. In this paper, we work with irreducible curves in a non-primitive ample linear system $|mH|$ and prove that Mukai’s program is valid for any irreducible curve when $g \neq 2$, $mg \geq 11$ and $mg \neq 12$. Furthermore, we introduce the destabilising regions to improve Feyzbakhsh’s analysis in [10]. We show that there are hyper-Kähler varieties as Brill–Noether loci of curves in every dimension.

1. Introduction

Let $F_g$ be the moduli stack of primitively polarised K3 surface $(X,H)$ with $H^2 = 2g - 2$ and let $P_{gm}$ be the moduli stack of triples $[(X,H,C)]$ such that $(X,H) \in F_g$ and $C \in |mH|$ a smooth curve of genus $g_m = m^2(g - 1) + 1$. There are natural forgetful maps

$$\Phi_{gm} : M_{gm} \to F_g \quad \Psi_{gm} : P_{gm} \to M_{gm}$$

where the fibre of $\Phi_{gm}$ over $(X,H) \in F_g$ is an open subset of the linear system $|mH|$. In recent years, there is a series of works studying the rational map $\Psi_{gm}$ and its rational inverse. For instance, Mukai has proved in [15] that the rational map $\Psi_g$ is dominant if $g \leq 11$ and $g \neq 10$, while Ciliberto–Lopez–Miranda [7] showed that $\Psi_g$ is generically injective if $g \geq 11$ and $g \neq 12$. More generally, due to the results of [8] and the recent work in Ciliberto–Dedieu–Sernesi [5, 4], the map $\Psi_{gm}$ is generically finite when $mg \geq 11$ and $mg \neq 12$. There are other approaches for the case $m \geq 2$, $g \geq 8$ or $m \geq 5, g = 7$ (cf. [6, 13]).

On the contrary, Mukai has proposed a program in [17] to find the rational inverse of $\Psi_g$ by relating the K3 surface with the Brill–Noether locus of vector bundles on curves. This has been confirmed by Mukai in [16] when $g = 11$ and later on Arbarello–Bruno–Sernesi [1] generalised his result to the case $g = 4k + 3$ for some $k$. In recent years, Feyzbakhsh has verified this program in [11, 12] for all $g \geq 11$ and $g \neq 12$ by using the Bridgeland stability conditions. In this paper, we would like to investigate the rational inverse of the map $\Psi_{gm}$ for arbitrary $m \in \mathbb{Z}_{>0}$ via Mukai’s program for curves in non-primitive classes.

Main results. Let $(X,H)$ be a primitively polarised K3 surface of genus $g$ with Picard number one. Let $H^*_\text{alg}(X) \cong \mathbb{Z}^{b_3}$ be the algebraic Mukai lattice and let $M(v)$ be the moduli space of $H$-Gieseker semistable coherent sheaves on $X$ with Mukai vector $v \in H^*_\text{alg}(X)$. The first main result of this paper is

**Theorem 1.1.** Assume $g > 2$. Let $C \in |mH|$ be an irreducible curve. Then if $mg \geq 11$ and $mg \neq 12$, there exists a primitive Mukai vector $v = (r,c,s)$ with $v^2 = 0$ such that the restriction map

$$\psi : M(v) \to \text{BN}_C(v)$$

$$E \mapsto E|_C$$

(1.1)
is an isomorphism. Here, $\text{BN}_C(v)$ is the Brill–Noether locus of slope stable vector bundles on $C$ with rank $r$, degree $2mc(g-1)$ and $h^0 \geq r+s$.

As in [11], one can then reconstruct $X$ as the moduli space of twisted sheaves on $\text{BN}_C(v)$. Clearly, such reconstruction is unique for K3 surfaces in $\mathcal{F}_g$ of Picard number one. Due to the results of [9], when $m > 1$, generic curves in $[mH]$ have maximal variation, i.e. the rational map

$$[mH] \dashrightarrow \mathcal{M}_{dm}$$

(1.2)

is generically finite. One can also deduce the generic quasi-finiteness of $\Psi_{gm}$ from Theorem 1.1 when $m > 1$, $g \geq 3$, $mg \geq 11$ and $mg \neq 12$. When $g_m < 11$, the map $\Psi_{gm}$ is not generically quasi-finite and Mukai’s program will fail. We expect that Theorem 1.1 holds whenever $g_m \geq 11$. So far, the missing values of $(g, m)$ are

$(2, m)$ with $m \geq 4$, $(3, 3)$, $(3, 4)$, $(4, 2)$, $(4, 3)$, $(5, 2)$, $(6, 2)$.

A mysterious case is when $g = 2$, where our method fails for any $m$.

More generally, one may consider the restriction map (1.1) for $v^2 = 2n > 0$. Most recently, Feyzbakhsh [10] has generalised her construction in [11, 12] and showed that for each Mukai vector $v = (r, c, s)$ satisfying

$$c < r, \ \gcd(r, c) = \gcd(c, s) = 1 \ \text{and} \ -2 \leq v^2 \leq -2 + r,$$

(1.3)

the restriction gives an isomorphism $M(v) \cong \text{BN}_C(v)$ when $g$ is sufficiently large and the class of $C$ is primitive. As mentioned in [10], the analysis in [10] also works for the non-primitive case and one can actually show that Feyzbakhsh’s construction still gives an isomorphism for $C \in [mH]$ if $g$ is sufficiently large (depending on $r$ and $m$). This gives many examples of Brill–Noether loci on curves as hyper-Kähler varieties of dimension $2g - 2r[2]$. In this paper, we also improve her result (see Theorem 7.1) and obtain an explicit condition of $v$ for $\psi$ being an isomorphism (see Theorem 7.3).

As an application, we show that one can construct hyper-Kähler varieties as the Brill–Noether loci of curves in every dimension.

**Theorem 1.2.** For any $n > 0 \in \mathbb{Z}$, there exists an integer $N = N(n)$ satisfying that if $g > N$, there is a primitive Mukai vector $v \in H^{*}_{\text{alg}}(X)$ with $v^2 = 2n$ such that the restriction map $\psi : M(v) \rightarrow \text{BN}_C(v)$ is an isomorphism for all irreducible curves $C$ on $X$.

The strategy of our proof is similar to [11, 12, 10]. Roughly speaking, we prove that $\psi$ will be a well-defined and injective morphism if the Gieseker chambers for objects with Mukai vector $v$ and $v(-m) := e^{-mH}v$ are large enough, and $\psi$ is surjective if the Harder–Narasimhan polygon of $i_*F$ for $F \in \text{BN}_C(v)$ achieves its maximum. The main ingredient is the use of wall-crossing argument to analyse the existence of walls. There are two crucial improvement in our approach. One is that we find the strongest criterion (Proposition 3.4) to characterise the stability conditions not lying on the wall of objects with a given Mukai vector. This leads to a more explicit condition for $\psi$ being an isomorphism. The other one is that we develop a method in analysing the relative position of HN polygons towards the surjectivity of $\psi$. This allows us to get a sharper bound of $(g, m)$ without using the computer program.

**Organization of this paper.** In Section 2, we review the basic knowledge of the Bridgeland stability condition on K3 surfaces and the wall-chamber structure on a section. In Section 3, we introduce the (strictly) destabilising regions $\Omega^{(+)}(-)$ of a Mukai vector $v$. They exactly characterise the stability conditions which are not lying on the wall of objects in $D^b(X)$ with Mukai vector $v$. This will play a key role in the proof of our main theorems.

In Section 4, we show that the map $\psi : M(v) \rightarrow \text{BN}_C(v)$ is a well-defined morphism and $h^0(X, E) = r + s$ for any $E \in M(v)$ if the positive integers $r, c$ and $s$ satisfy

$$\gcd(r, c) = 1, r > \frac{v^2 + 2}{2} \ \text{and} \ g - 1 \geq \begin{cases} r, & \text{if } v^2 = 0; \\ \max \left\{ \frac{v^2}{c} > r, \frac{v^2}{mr-c} \right\}, & \text{if } v^2 > 0. \end{cases}$$

(1.4)
The first two assumptions provide that any stable sheaf in \(M(v)\) is locally-free while the third assumption essentially ensures that there is no wall between the large volume limit and the Brill–Noether wall. As a by-product, we obtain a numerical criterion for the injectivity of \(\psi\).

Section 5 and Section 6 are devoted to studying the surjectivity of the restriction map \(\psi\). They contain the most technical part of this paper. In Section 5, we show that \(\psi\) is surjective if the Harder–Narasimhan polygon of \(i_*F\) for arbitrary \(F \in \text{BN}_C(v)\) is maximal when \(g\) is relatively large. It involves a dedicated analysis of the slope of destabilising factors of \(i_*F\) via a geometric vision of the destabilising region. In Section 6, we analyse the sharpness of \(\text{HN}\)-polygons for special Mukai vectors with zero square. The concept of sharpness is used to detect how far the \(\text{HN}\)-polygon stays away from the convex polygon given by the critical position of the first wall. This makes the construction valid for small genera.

In Section 7, we analyse the surjectivity of the tangent map \(d\psi\) of \(\psi\) and show that it is always surjective if \(g - 1 \geq 4v^2\). In Section 8, we prove Theorem 1.1 and Theorem 1.2 by showing the existence of Mukai vectors satisfying all conditions. Here, we make use of the bound of prime character nonresidues.

**Notation and conventions.** Throughout this paper, we always assume \((X, H)\) is a primitively polarised K3 surface of genus \(g\) of Picard number one.

For any two points \(p, q \in \mathbb{R}^n\), let \(L_{p,q}\) be the line passing through them and let \(L_{p,q}^+\) be the ray starting from \(p\). We use \(L_{[p,q]}, L_{(p,q)}, L_{(p,q)}\) and \(L_{(p,q)}\) to denote the closed, open, and half open line segment respectively. For any line segment \(I\), we set

\[\Delta_p(I) = \bigcup_{q \in I} L_{(p,q)}\]

to be a (half open) triangular region. We denote by \(P_{p_1 \ldots p_n}\) the polygon with vertices \(p_1, \ldots, p_n\).

### 2. Stability condition on K3 surfaces

Let \(\text{D}^b(X)\) be the bounded derived category of coherent sheaves on \(X\). We let \(K_{\text{num}}(X)\) be the Grothendieck group of \(X\) modulo numerical equivalence. It is onto the (algebraic) Mukai lattice \(H^*_{\text{alg}}(X) := H^0(X, \mathbb{Z}) \oplus \text{NS}(X) \oplus H^4(X, \mathbb{Z})\) via the map

\[v(E) = \text{ch}(E)\sqrt{\text{td}(X)} \in H^*_{\text{alg}}(X)\]

As \(X\) has Picard number one, we may identify \(H^*_{\text{alg}}(X)\) as \(\mathbb{Z}^{\mathbb{R}^3}\) and write \(v(E) = (r, c, s)\) with \(r = \text{rk}(E), c_1(E) = cH\) and \(s = \chi(E) - r\). The Mukai pairing \(\langle \cdot, \cdot \rangle\) on \(H^*_{\text{alg}}(X)\) can be viewed as an integral quadratic form on \(\mathbb{Z}^{\mathbb{R}^3}\) given by

\[\langle (x, y, z), (x', y', z') \rangle = 2yy'(g - 1) - xx' - zx'.\]

We may write \(v^2 = \langle v, v \rangle\) for \(v \in H^*_{\text{alg}}(X)\). Consider the projection map

\[\text{pr} : H^*_{\text{alg}}(X) \otimes \mathbb{R} \setminus \{s = 0\} \to \mathbb{R}^2\]

sending a vector \(v = (r, c, s)\) to \(\left(\frac{r}{s}, \frac{c}{s}\right)\). We write \(\pi_v = \text{pr}(v)\) and \(\pi_E = \text{pr}(v(E))\) for \(E \in \text{D}^b(X)\) for simplicity. We let \(O = (0, 0, 0)\) be the origin of \(H^*_{\text{alg}}(X) \otimes \mathbb{R}\) and denote by \(o = (0, 0)\) the origin of \(\mathbb{R}^2\).

A **numerical (Bridgeland) stability condition** on \(X\) is a pair \(\sigma = (\mathcal{A}_\sigma, Z_\sigma)\) consisting a heart \(\mathcal{A}_\sigma \subset \text{D}^b(X)\) of a bounded t-structure and an \(\mathbb{R}\)-linear map

\[Z_\sigma : K_{\text{num}}(X) \otimes \mathbb{R} \to \mathbb{C}\]

satisfying the conditions.
(i) For any $0 \neq E \in \mathcal{A}$,
$$Z_{\sigma}(E) \in \mathbb{R}_{>0} \exp(i\pi \phi_{\sigma}(E)) \text{ with } 0 < \phi_{\sigma}(E) \leq 1$$

where $\phi_{\sigma}(E)$ is the phase of $Z_{\sigma}(E)$ in the complex plane.

(ii) The Harder–Narasimhan (HN) Property, cf. [2, Definition 2.3].

The $\sigma$-slope is defined by
$$\mu_{\sigma}(E) = -\frac{\text{Re} Z(E)}{\text{Im} Z(E)}$$

and we set the $\sigma$-phase to be
$$\phi_{\sigma}(E) = \frac{1}{\pi} \left[ \pi - \cot^{-1}(\mu_{\sigma}(E)) \right] \in (0, 1].$$

An object $E \in \mathcal{A}$ is called $\sigma$-(semi)stable if $\mu_{\sigma}(F) < (\leq) \mu_{\sigma}(E)$ or equivalently $\phi_{\sigma}(F) < (\leq) \phi_{\sigma}(E)$ whenever $F \subset E$ is a subobject of $E$ in $\mathcal{A}$. We say an object $E \in \mathbb{D}^b(X)$ is $\sigma$-(semi)stable if $E[k] \in \mathcal{A}$ for some $k$, and $E[k]$ is $\sigma$-(semi)stable.

If $E$ is a sheaf, we write $\mu_{H}(E) = \frac{z}{\phi}$ as the $H$-slope of $E$. There is an associated phase function $\phi_{H}(E)$, which can be viewed as the limit of $\phi_{\sigma}$ by tending $\sigma$ to $o$. We write $\mu_{H}^{+}(E)$ for the $H$-slope of the first/last HN factor of $E$.

In [3], Bridgeland has constructed a continuous family of stability conditions on $X$ as follows: for $\alpha, \beta \in \mathbb{R}$ with $\alpha > 0$, for any $\beta \in \mathbb{R}$, the $\beta$-tilt of $\text{Coh}(X)$ is defined by
$$\text{Coh}^{\beta}(X) := \left\{ E \in \mathbb{D}^b(X) \bigg| \mu_{H}^{+}(E) \leq \beta, \mu_{H}(E) > \beta, \mu_{H}(E) \neq 0 \text{ for } i \neq 0, -1 \right\}$$

which is the heart of a t-structure on $\mathbb{D}^b(X)$ with
$$Z_{\alpha, \beta}(E) = \left\langle (1, \beta, \frac{H^2}{2}(\beta^2 - \alpha^2), v(E)), \frac{1}{\beta - \beta_{+}} \right\rangle + \sqrt{-1} \left\langle (0, \frac{1}{H^2}, 1, v(E)) \right\rangle,$$

**Theorem 2.1.** [3] The pair $\sigma_{\alpha, \beta} := (\text{Coh}^{\beta}(X), Z_{\alpha, \beta})$ is a Bridgeland stability condition on $\mathbb{D}^b(X)$ if $\text{Re} Z_{\alpha, \beta}(\delta) > 0$ for all roots $\delta \in R(X)$ with $\text{rk}(\delta) > 0$ and $\text{Im} Z_{\alpha, \beta}(\delta) = 0$.

The stability condition $\sigma_{\alpha, \beta}$ is uniquely characterised by its kernel
$$\text{ker} Z_{\alpha, \beta} = \left\{ (r, c, s) \in H_{\text{alg}}^{*}(X) \bigg| c = r \beta, s = \frac{rH^2}{2}(\alpha^2 + \beta^2) \right\}.$$

According to [11, Lemma 2.4], if we set $k(\alpha, \beta) = \text{pr(ker } Z_{\alpha, \beta}) \in \mathbb{R}^2$, then $k(\alpha, \beta)$ are parameterised by the space
$$V(X) = \left\{ (x, y) \in \mathbb{R}^2 \bigg| x > \frac{H^2 y^2}{2} \right\} \setminus \bigcup_{\delta \in R(X)} L_{\pi_{\delta}, \pi_{\delta}}$$

where $R(X)$ is the collection of roots in $H_{\text{alg}}^{*}$. Therefore, we may view the stability condition $\sigma_{\alpha, \beta}$ as a point in $V(X)$. The following are some simple observations that will be frequently used in this paper:

(A) If $\sigma \in V(X)$, then the line segment $L_{(0, \sigma)}$ is contained in $V(X)$.

(B) If $\gcd(r, c) = 1$ and $r > 0$, the line $ry = c\sigma$ contains a (unique) projection of root if and only if $r | c^2(y - 1) + 1$ (cf. [19]). In particular, the unique projection of root on the $x$-axis is $(1, 0)$, which we denote by $o'$.

A simple observation is, for elements in the same heart, we can read their phases from the plane.

**Proposition 2.2** (Phase reading). Fix $\sigma_{\alpha, \beta} \in V(X)$. For $E \in \text{Coh}^{\beta}(X)$, let $0 < \theta_{\alpha} \leq \pi$ be the directed angle from $\overline{\sigma \pi E_{F}}$ to $\overline{o \theta}$ modulo $\pi$. Then, $\phi_{\sigma}$ is a strictly increasing function of $\theta_{\sigma}$.

**Proof.** Note that $\phi_{\sigma}(E_{1}) = \phi_{\sigma}(E_{2})$ if and only if
$$v(E_{1}) + \lambda v(E_{2}) \in \text{ker } Z_{\alpha, \beta}.$$
for some $\lambda \in \mathbb{R}^+$, which is equivalent to $\sigma, \pi_0, \pi_1 \subseteq V(X)$ being colinear, as $\sigma \in V(X)$ is precisely the projection of the kernel of $Z_\sigma$. This already proves $\phi_\sigma$ is a strictly monotonic function of $\theta_\sigma$ due to continuity. It is increasing since $\phi_\sigma(0+) < \phi_\sigma(\pi)$. The interchange phase $\phi_\sigma = 1$ corresponds to the line $L_{0,\sigma}$.

Wall and chamber structure. For any object $E \in D^b(X)$, there is a wall and chamber structure of $V(X)$ described as follows.

**Proposition 2.3** (cf. [11, Proposition 2.6]). Given an object $E \in D^b(X)$, there exists a locally finite set of walls (line segments) in $V(X)$ with the following properties:

(a) The $\sigma_{a,\beta}$-(semi)stability of $E$ is independent of the choice of the stability condition $\sigma_{a,\beta}$ in any chamber.

(b) If $\sigma_{a_0,\beta_0}$ is on a wall $W_E$, i.e. the point $k(\alpha_0,\beta_0) \in W_E$, $E$ is strictly $\sigma_{a_0,\beta_0}$-semistable.

(c) If $E$ is semistable in one of the adjacent chambers to a wall, then it is unstable in other adjacent chambers.

(d) Any wall $W_E$ is a connected component of $L \cap V(X)$, where $L$ is a line passing through the point $\pi_E$ if $\chi(E) \neq \text{rk}(E)$, or with slope $\text{rk}(E)/c_H(E)$ if $\chi(E) = \text{rk}(E)$.

By definition, if $E \in \text{Coh}^b(X)$ is $\sigma_{a,\beta}$-semistable, then $\pi_E \notin \sigma_{a,\beta}$. Combined with Proposition 2.3, one can see that for any line segment $L_{[\sigma_1,\sigma_2]} \subseteq V(X)$ containing $\sigma_{a,\beta}$ with $\sigma_1, \sigma_2$, and $\pi_E$ colinear, we have

$$\pi_E \notin L_{[\sigma_1,\sigma_2]}. \quad (2.2)$$

This will be used in later sections.

3. The destabilising regions

In this section, we characterise the stability conditions which are not lying on the walls of an object $E \in D^b(X)$. As a warm up, we first assume $\pi_E \in \Omega V(X)$ and hence $v(E)^2 = 0$ or $-2$. Then we have

**Proposition 3.1** (Triangle rule). Let $E \in D^b(X)$ and let $I \subseteq V(X)$ be a line segment. Assume

$$\Delta_{\pi_E}(I) \subseteq V(X). \quad (3.1)$$

Then any point in $I$ is not on a wall. In particular, if $I = L_{[\sigma_1,\sigma_2]}$, then $E$ is $\sigma_1$-stable if and only if it is $\sigma_2$-stable.

**Proof.** Assume on the contrary, i.e. there is a wall $W_E \subseteq L \cap V(X)$ where $L$ passes through $\pi_E$ and intersects with $I$. Let $\sigma_0 = I \cap W_E$. By our assumption, one has

$$L_{(\pi_E,\sigma_0)} \subseteq W_E \subseteq V(X).$$

By Proposition 2.3 (b), $E$ is strictly $\sigma$-semistable for any $\sigma \in L_{(\pi_E,\sigma_0)}$. Up to a shift, one may assume that $E \in \text{Coh}^b(\sigma_0)(X)$. Since $\sigma_0$ is on a wall, there exists some semistable factor $F \subset E$ in $\text{Coh}^b(\sigma_0)(X)$.
such that \( \phi_{\sigma_0}(F) = \phi_{\sigma_0}(E) \) and \( \phi_\sigma(F) \geq \phi_\sigma(E) \) for \( \sigma \) in an adjacent chamber. In particular, \( \pi_F \neq \pi_E \). Applying Proposition 2.3(b) to \( E, F \), and \( \cok(F \to E) \) respectively, we know that they remain in the heart for any \( \sigma \in L_{(\pi_E, \sigma_0)} \). Hence \( F \subset E \) is a proper subobject in the corresponding \( \text{Coh}^b(X) \). As a consequence, we get

\[
0 < |Z_\sigma(F)| < |Z_\sigma(E)|.
\]

Now, if we tend \( \sigma \) to \( \pi_E \), then \( |Z_\sigma(E)| \to 0 \) while \( |Z_\sigma(F)| \to \epsilon > 0 \) since \( \pi_F \neq \pi_E \). This is a contradiction.

\[\blacklozenge\]

**Destabilising regions.** The Proposition above only works for \( \pi_E \in \partial V(X) \) due to (2.2). For the case \( v(E)^2 \geq 0 \), we need to make use of the three-dimensional region defined as below: for any \( \sigma \in V(X) \) and \( v \in H^{3\text{,alg}}(X) \), let \( L_{(\sigma', \sigma'')} \subseteq L_{\sigma, \pi_v} \cap V(X) \) be the connected component containing \( \sigma \). Let \( [\sigma] \subseteq \mathbb{R}^3 \) be the preimage of \( \sigma \) via the projection \( \frac{\partial}{\partial u} \to \mathbb{R}^2 \). We define the **destabilising region of \( v \) with respect to \( \sigma \)** as

\[
\Omega_v(\sigma) = (P_{\Omega_{\sigma^+} \cap v}) \cap \{u \in \mathbb{R}^3 \mid u^2 \geq -2, (u - v)^2 \geq -2\},
\]

where \( v_\sigma^+ = [\sigma'] \cap ([\sigma'] + v) \) and \( v_\sigma^- = [\sigma'] \cap ([\sigma'] + v) \). Up to switching \( \sigma' \) and \( \sigma'' \), we may always let

\[
\begin{align*}
v_\sigma^+ &\in \{(x, y, z) \mid x \geq 0, z \geq 0\} \quad \text{and} \quad v_\sigma^- \in \{(x, y, z) \mid x \leq 0, z \leq 0\}.
\end{align*}
\]

There is a natural decomposition

\[
\Omega_v(\sigma) = \Omega_v^+(\sigma) \cup L_{(\sigma, v)} \cup \Omega_v^-(\sigma),
\]

where \( \Omega_v^+(\sigma) = \Omega_v^+(\sigma) \cap P_{\sigma^+ \cap v} \). We call \( \Omega_v^+(\sigma) \) the **strictly destabilising region of \( v \) with respect to \( \sigma \)**. A key result is

**Lemma 3.2.** For \( E \in \text{D}^b(X) \) and \( \sigma \in V(X) \), if \( \sigma \) is lying on a wall of \( E \), then there exists an integer point in \( \Omega_v^+(\sigma) \).

**Proof.** Set \( v = v(E) \) for temporary notation. Firstly, for any \( G \subseteq F \subseteq E \) in \( \text{Coh}^b(\sigma) \) satisfying that \( E, F, G \) have the same \( \sigma \)-phase, we always have that \( v(F/G) \) is lying in the parallelogram \( P_{\Omega_{(\sigma^+) \cap v}} \). This is because there are inclusions

\[
L_{[0, Z_\tau(F/G)]} \subseteq L_{[0, Z_\tau(F)]} \subseteq L_{[0, Z_\tau(E)]}
\]

for any \( \tau \in L_{(\sigma', \sigma'')} \), which yields that

\[
v(F/G) \in \bigcap_{\tau \in L_{(\sigma', \sigma'')}} Z_\tau^{-1}(L_{[0, Z_\tau(v)]}) = P_{\Omega_{(\sigma^+) \cap v}}.
\]

In particular, if \( 0 = \tilde{E}_0 \subset \cdots \subset \tilde{E}_k = E \) is a \( \sigma \)-JH filtration of \( E \) with \( E_i = \tilde{E}_i/\tilde{E}_{i-1} \) its JH-factors, then any \( v(E_i) \) and also \( v - v(E_i) \) is lying \( P_{\Omega_{(\sigma^+) \cap v}} \).
If necessary, reordering these factors $E_i$ such that the angles between $L_{O,v}(E_i)$ and $L_{O,v^+}$ increase. Then $\sum_j v(E_i)$ is an integer point in $P_{O,v^+} \setminus L(O,v)$ for any $j$. We claim that either $v(E_1)$ or $\sum_{i=1}^{k-1} v(E_i)$ is lying in $\Omega_v(\sigma)$. This can be proved by using purely Euclidean geometry. Suppose this fails, then we have

$$v(E_1)^2 \geq -2 \quad \text{and} \quad (v(E_1) - v)^2 < -2,$$

$$\sum_{i=1}^{k-1} v(E_i) - v)^2 \geq -2 \quad \text{and} \quad (\sum_{i=1}^{k-1} v(E_i))^2 < -2,$$

as $E_i$ is stable. If we restrict the quadratic equation $u^2 = -2$ to the plane of $P_{O,v^+}$, we can obtain a hyperbola, whose center is $O$. The edge $L_{O,v^+}$ can meet the connected component of this hyperbola at most one point. Similarly, $L_{v,v^+}$ can intersect with the connected component of the hyperbola defined by $(u - v)^2 = -2$ at most one point. Note that the edge $L_{O,v}$ is lying outside the area

$$\left\{ u^2 < -2, (u - v)^2 < -2 \right\}.$$

see the shadow part in Figure 3. By (3.2), $v^+_\sigma$ has to lie in the region (3.3). Moreover, as one can see from the picture, there is a point $w \in P_{O,v^+}$ lying on the intersection of two hyperboloids

$$\left\{ u \in \mathbb{R}^3 \mid u^2 = -2 \right\} \cap \left\{ u \in \mathbb{R}^3 \mid (u - v)^2 = -2 \right\},$$

and the line $L_{w,v^+}$ will intersect the edge $L_{O,v}$ at a point, denoted by $q$. Thus we get that the point $v(E_1)$ is contained in the triangle $P_{q,v^+}$, while the point $\sum_{i=1}^{k-1} v(E_i)$ is contained in the triangle $P_{O,v^+}$. If we define $L_u$ to be the line passing through $u \in \mathbb{R}^3$ and parallel to the line $L_{w,v^+}$, the discussion above exactly means

$$L_{[O,v]} \subset L_{[O,q]} \subset L_{[O,p^2]}$$

where $p_1 = L_{\sum_{i=1}^{k-1} v(E_i)} \cap L_{[O,v]}$ and $p_2 = L_{v(E_1)} \cap L_{[O,v]}$, see Figure 3.

Next, one can regard $L_{w,v^+}$ as a stability condition in a natural way (by taking the projection of the one dimensional vector space determined by $L_{w,v^+}$). Denote this stability condition by $\tau$. Then for any two points $p,p'$ with $L_{p,p'}$ parallel to $L_{w,v^+}$, there is $Z(\tau) = Z(\tau')$. Using the inclusions
we obtain the inequality
\[
\frac{|Z_\tau (v(E_i))|}{Z_\tau (\sum_{i=1}^{k-1} v(E_i))} = \frac{|Z_\tau (p_2)|}{Z_\tau (p_1)} = \frac{\|L_{[O,p_2]}\|}{\|L_{[O,p_1]}\|} > 1. \tag{3.6}
\]
However, this contradicts to the relation $\sum_{i=1}^{k-1} |Z_\tau (v(E_i))| = |Z_\tau \left( \sum_{i=1}^{k-1} v(E_i) \right) |$ which finishes the proof.

\textbf{Remark 3.3.} If $v(\tilde{E}_i)$ already lies in $\mathbf{P}_{O,v} \setminus L_{(O,v)}$ for all $i$, then our argument actually shows that we can always take a destabilising sequence
\[ F \rightarrow E \rightarrow Q \]
such that $v(F) \in \Omega^+_v(\sigma)$. This will happen, for instance, if $E = i_* F$ for some slope stable vector bundle $F$ on $C$.

Then we can obtain a generalisation of Proposition 3.1.

\textbf{Proposition 3.4.} Given a region $\mathcal{I} \subseteq V(X)$, we define
\[
\Omega_v(\mathcal{I}) = \bigcup_{\sigma \in \mathcal{I}} \Omega_v(\sigma) \quad \text{and} \quad \Omega_v^+(\mathcal{I}) = \bigcup_{\sigma \in \mathcal{I}} \Omega_v^+(\sigma).
\]
Then any $\sigma \in \mathcal{I}$ is not lying on a wall of any $E$ with $v(E) = v$ if and only if
\[
\Omega_v^+(\mathcal{I}) \cap H_{\operatorname{alg}}^*(X) = \emptyset. \tag{3.7}
\]
Similarly, any $E$ with $v(E) = v$ cannot be strictly $\sigma$-semistable for any $\sigma \in \mathcal{I}$ if and only if
\[
\Omega_v(\mathcal{I}) \cap H_{\operatorname{alg}}^*(X) = \emptyset. \tag{3.8}
\]

\textbf{Proof.} The ‘if’ part follows directly from Lemma 3.2. For the ‘only if’ part, suppose there exists some stability condition $\sigma$ and an integer point $w \in \Omega_v(\sigma)$. Then, we can find $\sigma$-stable objects $F_1$ and $F_2$ such that $v(F_1) = w$ and $v(F_2) = v - w$, and $\sigma$ will be lying on a wall of $E := F_1 \oplus F_2$ from the construction. For the strictly semistable case, one just notes that the Mukai vectors of all the factors are lying on $L_{(O,v)}$.

According to Proposition 3.4, we will say a Mukai vector $v \in H_{\operatorname{alg}}^*(X)$ admits no wall in $\mathcal{I}$ if (3.7) holds, and admits no strictly semistable condition if (3.8) holds.

Note that from the definition, one automatically has $\Omega_v(\sigma) = \Omega_v(L_{(\sigma',\sigma'')})$. This motivates us to find a subregion of $V(X)$ with regular boundary. A candidate is
\[
\Gamma = \left\{ (y, x) \in \mathbb{R}^2 \mid x > gg^2, x < \sqrt{2/H^2} \text{ when } y = 0 \right\} \subseteq V(X) \tag{3.9}
\]
which is used in [10]. As a consequence, if $v$ admits no wall in $I \subseteq L_{(o,o')}$, then it admits no wall in $\Delta_{\pi_v}(I) \cap \Gamma$ as well.

\textbf{Remark 3.5.} Comparing Proposition 3.1 with Proposition 3.4, one can conclude that for $v^2 = 0$ and $\mathcal{I}$ being a line segment, the condition (3.1) implies (3.7). Actually, if $\Omega_v^+(\sigma)$ contains any integer point $\delta$, then $\pi_\delta$ is a root lying in $L_{(\pi_v,\sigma)}$. This suggests that the condition (3.1) can be replaced by $\Delta_{\pi_v}(I) \subseteq V'(X)$, where
\[
V'(X) = \left\{ (x, y) \in \mathbb{R}^2 \mid x > \frac{H^2 y^2}{2} \right\} \setminus \bigcup_{\delta \in \Gamma(X)} \{ \pi_\delta \}.
\]
4. The restriction map to Brill–Noether locus

Given a positive primitive vector \( v = (r, c, s) \in H^* \) \(_{\text{alg}}(X)\), let \( M(v) \) be the moduli space of \( H \)-Gieseker semistable sheaves on the surface \( X \) with Mukai vector \( v \). In this section, we always assume \( r, c, s > 0 \) and
\[
\gcd(r, c) = 1 \text{ and } r > \frac{c^2}{2} + 1.
\]
Then \( M(v) \) is a smooth variety consisting of \( \mu_H \)-stable locally free sheaves (cf. [20, Remark 3.2]). The main result is

**Theorem 4.1.** For any irreducible curve \( C \in |mH| \), the restriction map is an injective morphism
\[
\psi : M(v) \to \text{BN}_C(v),
\]
\( E \mapsto E|_C \) with stable image (i.e. \( E|_C \) is stable) if the following conditions hold

- \((mr - c)s > rc\);
- \( v \) admits no wall in \( L_{(o, \sigma_v)} \), where \( \sigma_v = \left(\frac{rc}{(mr - c)s}, 0\right) \);
- \( v(-m) = (r, c - mr, s + (g - 1)m(r - 2c)) \) admits no wall in \( \Delta_{\pi_v(-m)}(L_{(o, o')}) \cap \Gamma \), where \( \Gamma \) is defined in (3.9).

**Proof.** It suffices to prove that for any \( E \in M(v) \), the restriction \( E|_C \) is slope stable with \( h^0(C, E|_C) \geq r + s \) and \( E|_C \) uniquely determines \( E \).

Firstly, we show that \( E|_C \) is slope semistable. By [11, Lemma 2.13 (b)], it suffices to show that \( i^*(E|_C) \) is \( \sigma_v \)-semistable. Consider the exact sequence
\[
0 \to E(-C) \to E \to i^*(E|_C) \to 0,
\]
we have \( \pi^*(E|_C) = \left(\frac{r}{g - 1}, 0\right) \) lying on \( L_{\pi_{E}: \pi_{E(-C)}} \). Since \( E \) is slope stable, according to [11, Lemma 2.15], \( E \) is \( \sigma \)-stable for any \( \sigma \in L_{(o, o')} \cap V(X) \). Choose \( \sigma_1 \in L_{(o, o)} \) sufficiently close to \( o \). We have
\[
P_{o, \sigma_1} \setminus \{o\} \subseteq \Gamma \subseteq V(X)
\]
as in Figure 4. Note that for any line \( L \) passing through \( \pi_E \), the intersection \( P_{o, \sigma_1} \setminus \{o\} \cap L \) is connected. By our assumption, \( v \) admits no wall in \( L_{(o, o')} \). This implies it also admits no wall in \( P_{o, \sigma_1} \setminus \{o\} \). Hence \( E \) is \( \sigma_v \)-stable as \( E \) is \( \sigma_1 \)-stable. Similarly, we have \( E(-C) \) is also \( \sigma_v \)-stable. As in the proof of Proposition 2.2, \( E \) and \( E(-C) \) are of the same \( \sigma_v \)-phase since \( \sigma_v \in L_{\pi_E, \pi_{E(-C)}} \). Hence the restriction \( i^*(E|_C) \) is \( \sigma_v \)-semistable with \( E \) and \( E(-C)[1] \) as its JH-factors.
Secondly, we show that $E|_C$ is slope stable. By using [11, Lemma 2.13 (b)], we are reduced to prove $i_* (E|_C)$ is $\sigma$-stable for some $\sigma \in L_{(o,\sigma_v)}$. Moreover, due to [11, Lemma 2.13 (a)], $i_* (E|_C)$ is semistable for any stability condition lying in a line segment $L_{(o,a)} \subseteq L_{(o,\sigma_v)}$. Suppose that $i_* (E|_C)$ is strictly semistable for all stability conditions in $L_{(o,a)}$. Then for any $\sigma_0 \in L_{(o,a)}$ and any destabilising sequence

$$F_1 \hookrightarrow i_* (E|_C) \twoheadrightarrow F_2 \in \text{Coh}^{\beta=0} (X)$$

such that $F_1, F_2$ are $\sigma_0$-semistable with the same $\sigma_0$-phase as $i_* (E|_C)$, we have $\pi F_1 = \pi i_* (E|_C)$. This gives $\phi_{\sigma_0} (F_1) = \phi_{\sigma_0} (i_* (E|_C))$, which implies that $F_1$ is $\sigma_0$-semistable. However, this contradicts to the uniqueness of JH-factors of $i_* (E|_C)$ with respect to $\sigma_v$. Thus $i_* (E|_C)$ is $\sigma$-stable for some $\sigma \in L_{(o,a)}$.

Next, to show $h^0 (C, E|_C) \geq r + s$, let us consider the long exact sequence of cohomology induced by (4.1)

$$0 \rightarrow H^0 (X, E(-C)) \rightarrow H^0 (X, E) \rightarrow H^0 (C, E|_C)) \rightarrow H^1 (X, E(-C)) \rightarrow \ldots$$

As $E(-C)$ is $\mu_H$-stable and $\mu_H (E(-C)) < 0$, we have

$$H^0 (X, E(-C)) = \text{Hom}_X (O_X, E(-C)) = 0.$$

Then we choose $\sigma_2 \in L_{(\pi_{\sigma(-m)}, \sigma_v)}$ sufficiently close to $o$ and $\sigma_3 \in L_{(\pi_{\sigma(-m)}, \sigma_v)}$ sufficiently close to $o'$ so that $P_{\sigma_2 \sigma_3 \sigma_v} \setminus \{o, o'\} \subseteq \Gamma$, see Figure 4. As shown above, $E(-C)$ is $\sigma$-stable for any $\sigma \in P_{\sigma_2 \sigma_3 \sigma_v} \setminus \{o, o'\}$. In particular, $E(-C)$ is $\sigma_3$-stable. According to [11, Lemma 2.15], we have

$$P_{\sigma_2 \sigma_3 \sigma_v} \setminus \{o'\} \subseteq V(X)$$

and $O_X$ is also $\sigma_v$-stable. Note that $\pi_{O_X} = o'$. By Proposition 3.1 and Proposition 2.2, we know that $O_X$ is $\sigma_3$-stable and $\phi_{\sigma_3} (E(-C)) = \phi_{\sigma_3} (O_X)$. Then we have

$$H^1 (X, E(-C)) = \text{Hom}_{\mathcal{A}} (O_X, E(-C)[1]) = 0$$

where $\mathcal{A} = \text{Coh}^{\beta(\sigma_3)} (X)$. Therefore, we get an isomorphism $H^0 (X, E) \cong H^0 (C, E|_C)$. By Serre duality and the stability of $E$, we have $H^2 (X, E) \cong \text{Hom}_X (E, \omega_X) \cong \text{Hom}_X (E, O_X) = 0$. It follows that

$$h^0 (C, E|_C) = h^0 (X, E) \geq \chi (E) = r + s.$$  

(4.2)

This proves our claim.

In the end, the uniqueness of $E$ follows from the fact that the JH factors of $i_* (E|_C)$ are unique with respect to $\sigma_v$. 

**A numerical criterion.** As in [11], we would like to find a purely numerical condition for Theorem 4.1 to hold. An elementary result is

$$x = r/s$$

![Figure 5. $\pi_\delta$ in the interior of $P_{o\sigma_v\infty}$ (colored area)](image)

$$y = c/s$$

$$x = \frac{H^2}{2} y^2$$
Lemma 4.2. Let $P_{v,∞}$ be the trapezoidal region bounded by $L_{[0,∞)}$, the (positive) half $x$-axis $L_{[0,∞)}$ and the vertical ray $L_{[v,∞)}$ in Figure 5. Then $v$ admits no wall in $P_{v,∞} \cap \Gamma$ if one of the following conditions holds

(i) $v^2 = 0$ and $r / \gcd(r, c) \leq g - 1$.
(ii) $s = \left\lfloor \frac{(g-1)c^2 + 1}{r} \right\rfloor$ and $g - 1 \geq \max\{\frac{c^2}{r}, r + 1\}$

Proof. (i). By Proposition 3.1, it will be sufficient to show that $P_{v,∞} \subseteq V(X)$.

Due to the explicit description of $V(X)$ in (2.1), this is equivalent to showing that there is no projection of root lying in $P_{v,∞}$. Suppose there exists a root $δ = (r', c', s') \in R(X)$ with $π_δ \in P_{v,∞}$. Then we have

$$\frac{c'}{r'} \leq \frac{c}{r} \quad \text{and} \quad \frac{c'}{s'} \leq \frac{c}{s}. \quad (4.3)$$

see Figure 5. Note that $2rs = c^2(2g - 2)$ and $2r's' = (c')^2(2g - 2) + 2$, one can plug into (4.3) to get

$$\frac{r}{\gcd(r, c)} c' < \frac{r}{\gcd(r, c)} r' < \frac{r}{\gcd(r, c)} c' + \frac{r}{\gcd(r, c)} (g - 1)c' \leq \frac{r}{\gcd(r, c)} c' + 1. \quad (4.4)$$

which is not possible.

(ii). According to Proposition 3.4, we just need to show that $Ω^+_v(σ) \cap H^+_v(X) = ∅$ for any $σ \in P_{v,∞} \cap \Gamma$. Suppose there is an integer point $(x, y, z) \in Ω^+_v(σ_0)$ for some $σ_0 \in P_{v,∞}$. By the construction of $Ω^+_v(P_{v,∞} \cap \Gamma)$, we have $0 < y \leq c$ and the point $(x, y, z)$ is lying in the interior of the triangle $P_{u_1 u_2 u_3}$ with vertices

$$u_1 = (\frac{rω}{c}, y, \frac{ωy}{c}), \quad u_2 = (\frac{rω}{c}, y, \frac{ωy}{c}) \quad \text{and} \quad u_3 = (\frac{ωy}{c}, y, \frac{ωy}{c}).$$

As $y^2(g - 1) + 1 \geq xz$ and $z \geq \frac{ωy}{c}$, one has

$$\frac{ry}{c} < x < \frac{y^2(g - 1) + 1}{sy/c}. \quad (4.5)$$

Note that $c^2(g - 1) - \frac{c^2}{2} = rs$, the condition $s = \left\lfloor \frac{(g-1)c^2 + 1}{r} \right\rfloor$ is equivalent to $r > \frac{c^2}{2} + 1$. Then we have

$$0 < \frac{y^2(g - 1) + 1}{sy/c} - \frac{ry}{c} < \max\left\{\frac{gc}{s} \frac{r - c^2(g - 1) + 1}{s} - r\right\} = \max\left\{\frac{r(c^2 + \frac{c^2}{2})}{c(c^2(g - 1) - \frac{c^2}{2})}, \frac{r(\frac{c^2}{2} + 1)}{c^2(g - 1) - \frac{c^2}{2}}\right\} \leq \max\left\{\frac{r(c^2 + r - 2)}{c(c^2(g - 1) - r + 2)}, \frac{r^2 - r}{c^2(g - 1) - r + 2}\right\} \leq \frac{1}{c}.$$

Here, the last inequality follows from our assumption $g - 1 \geq \max\{\frac{r^2}{c}, r + 1\}$. This means $0 < x - \frac{ry}{c} < \frac{1}{c}$, which contradicts to the fact $x$ is an integer.

We summarise our numerical criterion as follows.

Corollary 4.3. The restriction map $ψ : M(v) → BN_C(v)$ is an injective morphism with stable image if

$$r > \max\left\{\frac{v^2}{2} + 1, \frac{c}{m}\right\}, \quad c > 0, \quad s > \frac{rc}{mr - c}, \quad \gcd(r, c) = 1 \quad (4.6)$$

and

$$g - 1 \geq \begin{cases} r, & \text{if } v^2 = 0 \\ \max\left\{\frac{v^2}{2}, \frac{v^2}{mr - c}, r + 1\right\}, & \text{if } v^2 > 0. \end{cases} \quad (4.7)$$
Proof. The condition $mr > c > 0$ ensures $\pi_v$ lies in the first quadrant while $\pi_{v(-m)}$ lies in the second quadrant, and the condition $s(mr - c) > rc$ ensures $\sigma$, is below $'$. The assertion then follows from the direct computation that $L_{(o,\sigma_v)} \subseteq \Delta_{\psi}(L_{(o,')}) \cap \Gamma \subseteq P_{o,\infty,\infty} \cap \Gamma$ for $w = v$ or $v(-m)$. \hfill \qed

Remark 4.4. Under the assumption $r > c$, the conditions in Corollary 4.3 can be easily reduced to (1.4).

5. Surjectivity of the restriction map

Throughout this section, we let $v = (r, c, s) \in H^*_\text{alg}(X)$ be a positive vector satisfying (4.6) and (4.7). Due to Corollary 4.3, the restriction map

$$\psi : M(v) \to BN_C(v)$$

is an injective morphism with stable image. Following the ideas in [11, 12], we give sufficient conditions such that $\psi$ is surjective.

The first wall. As in [11], we first describe the wall that bounds the Gieseker chamber of $i_*F$ for $F \in BN_C(v)$. The following result is an extension of [11, Proposition 4.2].

Theorem 5.1. For any $F \in BN_C(v)$, the wall that bounds the Gieseker chamber of $i_*F$ is not below the line $L_{\pi_v,\pi_{v(-m)}}$, and they coincide if and only if $F = E|_C$ for some $E \in M(v)$.

Proof. We will prove that for any $v$ under the condition (4.6), if both $v$ and $v(-m)$ admit no wall in $(o, \sigma_v)$, then so does $v|_C := v - v(-m)$.

Let $W_{i_*F}$ be the first wall and let $\sigma_{\alpha',0} \in W_{i_*F}$ be a stability condition. Suppose $W_{i_*F}$ is below or on the line $L_{\pi_v,\pi_{v(-m)}}$. Then there exists a destabilising sequence

$$F_1 \hookrightarrow i_*F \twoheadrightarrow F_2$$

(5.1)
in $\text{Coh}^{\beta=0}(X)$ such that $F_1, F_2$ are $\sigma_{\alpha',0}$-semistable, and

$$\phi_{\alpha,0}(F_1) > \phi_{\alpha,0}(i_*F) \quad \text{for} \quad \alpha < \alpha'.$$

(5.2)

Taking the cohomology of (5.1) gives a long exact sequence of sheaves

$$0 \to H^{-1}(F_2) \to F_1 \xrightarrow{d_0} i_*F \xrightarrow{d_1} H^0(F_2) \to 0.$$ 

(5.3)

Set $v(F_1) = (r', c', s')$, then we have $r' > 0$ by (5.2). Let $T$ be the maximal torsion subsheaf of $F_1$ and we can write $v(T) = (0, \hat{c}, \hat{s})$ for some $\hat{c}, \hat{s} \in \mathbb{Z}$. Consider the inclusions $T \hookrightarrow F_1 \hookrightarrow i_*F$ and take the cohomology, one can get

$$0 \to H^{-1}(\text{cok}) \to T \to i_*F \to H^0(\text{cok}) \to 0.$$ 

Since $H^{-1}(\text{cok})$ is torsion-free, it must be zero. It follows that $T$ is a subsheaf of $i_*F$ and $\text{rk}(i^*T) = \frac{\hat{c}}{m}$.

If we let $v(H^0(F_2)) = (0, c'', s'')$, by restricting (5.3) to the curve $C$, one can get

$$r' + \frac{\hat{c}}{m} = \text{rk}(F_1/T) + \text{rk}(i^*T) \geq \text{rk}(i^*F_1)$$

$$\geq \text{rk}(i^* \text{ker} d_1) \geq \text{rk}(i^*F) - \text{rk}(i^*H^0(F_2)) = r - \frac{c''}{m}.$$ 

In other words,

$$\mu(F_1/T) - \mu(H^{-1}(F_2)) = \frac{c - \hat{c}}{r'} - \frac{c'' - mr}{r'} \leq m.$$ 

(5.4)

Using Lemma 5.2 below, we can take the destabilising sequence (5.1) satisfying

$$\mu_H^-(F_1/T) \geq \frac{c}{r} \quad \text{and} \quad \mu_H^+(H^{-1}(F_2)) \leq \frac{c - mr}{r}.$$ 

(5.5)

This gives

$$\mu_H^-(F_1/T) - \mu_H^+(H^{-1}(F_2)) \geq m.$$ 

(5.6)
Combining (5.4) and (5.6), we get \( mr - c'' - \hat{c} = mr' \), thus
\[
\mu_H(F_1/T) = \frac{c' - \hat{c}}{r' \hat{c}} = \frac{c - \hat{c}}{r - \frac{c'' + c}{m}} = \frac{c}{r}
\]
and both \( F_1/T \) and \( H^{-1}(F_2) \) are \( \mu_H \)-semistable. Since \( \gcd(r, c) = 1 \) and \( i_* F \) does not contain any skyscraper sheaf, we have \( \hat{c} = c'' = 0 \) and \( \hat{s} = 0 \). This shows \( T = 0 \) and hence \( v(F_1) = (r, 1, s') \).

Note that by our assumption, we have \( \pi_v(F_1) \in L_{(o, \pi_v)} \), which means \( s < s' \). However, this gives \( v(F_1)^2 = 2r(s - s') < -2 \) which contradicts to the fact that \( F_1 \) is \( \mu_H \)-stable.

Assume that \( \mathcal{W}_{i_* F} \subseteq L_{\pi_v, \pi_v(m)} \). Then we have
\[
\mu_H^{-1}(F_1/T) - \mu_H(H^{-1}(F_2)) = m
\]
and \( F_1 \) is a stable sheaf. Note that the map \( d_0 : F_1 \to i_* F \) factors through \( d'_0: i_* (F_1|_C) \to i_* F \) and \( \mu_H(i_*(F_1|_C)) = \mu_H(i_* F) \). Applying Theorem 4.1 to \( F_1 \), we know that \( i_*(F_1|_C) \) is stable as well. It follows that \( d'_0 \) is an isomorphism.

**Lemma 5.2.** With notations and assumptions as above, one can find a destabilising sequence (5.1) such that \( F_i \) satisfies
\[
\mu_H^{-1}(F_1/T) \geq \frac{c}{r} \quad \text{and} \quad \mu_H(H^{-1}(F_2)) \leq \frac{c - mr}{r}. \tag{5.7}
\]

**Proof.** Denote \( \sigma_1 = \mathcal{W}_{i_* F} \cap L_{(o, \pi_v)} \). By Remark 3.3, we can take the destabilising sequence
\[
F_1 \mapsto i_* F \mapsto F_2
\]
satisfying \( v(F_i) \in \Omega_{\pi_v}^{+}(\sigma_1) \subseteq \Omega_{\pi_v}^{+}(L_{(o, \pi_v)}) \). We divide the proof into three steps.

**Step 1.** We show that for any point \( u = (x_0, y_0, z_0) \) with \( u^2 \geq -2 \) and \( x_0 > 0 \), \( u \) is lying in \( \Omega_{\pi_v}^{+}(L_{(o, \pi_v)}) \) if \( x_0 \leq r \) or \( z_0 \leq s \), and \( \pi_u \in \mathbf{P}_{o, \pi_v} \). By its definition, we know that \( u \in \Omega_{\pi_v}^{+}(L_{(o, \pi_v)}) \) if
\[
u \in \mathbf{P}_{O_{\pi_v}} \quad \text{and} \quad (u - v)^2 \geq -2.
\]
for some \( \sigma \in L_{(o, \pi_v)} \).

As \( \pi_u = (\frac{\pi_y}{\pi_z}, \frac{\pi_{y'}z_0}{\pi_z}) \) is lying in the interior of the triangle \( \mathbf{P}_{o, \pi_v} \), we have
\[
y_0 < \frac{c}{s} \quad \text{and} \quad \frac{x_0}{y_0} > \frac{r}{c}.
\]
(5.9)
The line \( L_{\pi_u, \pi_v} \) will meet the open edge \( L_{(o, \pi_v)} \). Denote by \( \sigma \) the intersection point \( L_{(o, \pi_v)} \cap L_{\pi_u, \pi_v}^{+} \). From the construction, we know that \( u \) is coplanar to \( v \), \( v_{\hat{c}} \) and \( O \). Indeed, it is lying in the planar cone bounded by the two rays \( L_{O, e} \) and \( L_{O, e}^{+} \). The condition \( x_0 \leq r \) or \( z_0 \leq s \) will ensure that \( u \in \mathbf{P}_{O_{\pi_v}}^{+} \).

Moreover, when \( x_0 \leq r, z_0 \geq s \) or \( x_0 \geq r, z_0 \leq s \), we have \( (u - v)^2 \geq (g - 1)(y_0 - c)^2 > 0 \). When \( x_0 \leq r \) and \( z_0 \leq s \), then we have
\[
(u - v)^2 \geq \frac{(c - y_0)^2}{c^2} v^2 > 0,
\]
by (5.9).

**Step 2.** Set \( v(F_1) = (r', c', s') \) and \( v(F_2) = (-r', mr - c', s - \hat{s} - s') \) with \( 0 < c' < mr \) and \( r' > 0 \). We claim that
\[
\mu_H(F_1) \geq \frac{c}{r} \quad \text{and} \quad \mu_H(F_2) \leq \frac{c - mr}{r}. \tag{5.10}
\]
Firstly, we must have either \( r' \leq r \) or \( s' \leq s \). Otherwise, one will have
\[
v(F_1)^2 < (g - 1)c^2 - r(s + 1) \leq -2
\]
or
\[
v(F_1) - v(F_2)^2 < (g - 1)(mr - c)^2 - r(\hat{s} + 1) \leq -2.
\]
Both of them are impossible as \( v(F_1) \in \Omega_{\pi_v}^{+}(L_{(o, \pi_v)}) \).
Now, suppose \( \mu_H(F_1) < \frac{c}{r} \). Then we have \( v(F_1) \in \mathbf{P}_{\sigma_1}^o \) as \( \phi_{\sigma_1}(v) \geq \phi_{\sigma_1}(v) \). According to Step 1, we get
\[
v(F_1) \in \Omega_+^v(L_{(o,\sigma_1)})
\]
which contradicts to the assumption \( \Omega_+^v(L_{(o,\sigma_1)}) \cap H^\text{alg}_{\text{red}}(X) = \emptyset \). Similarly, we have \( \mu_H(F_2) \leq \frac{c-mr}{r} \) as there is no integer point in \( \Omega_+^v(L_{(o,\sigma_1)}) \). This proves the claim. As a consequence, we get
\[
\frac{mr'}{r} = \mu_H(F_1) - \mu_H(F_2) \geq \frac{c}{r} - \frac{c - mr}{r} = m
\]
which implies \( r' \leq r \).

**Step 3.** Let \( (F_1)_{\text{min}} \) be the last \( \mu_H \)-HN factor of \( F_1 \), hence also of \( F_1/T \). According to [3, Proposition 14.2], for \( \sigma \) sufficiently close to \( o \), we always have
- \( (F_1)_{\text{min}} \) is \( \sigma \)-semistable,
- \( v(G) \) is proportional to \( v((F_1)_{\text{min}}) \) for any \( \sigma \)-stable factor \( G \) of \( (F_1)_{\text{min}} \).

As \( (F_1)_{\text{min}} \) is a quotient sheaf of \( F_1 \), it is also a quotient of \( F_1 \) in \( \text{Coh}^{\beta = 0}(X) \). Since \( F_1 \) is \( \sigma_1 \)-semistable, we have
\[
\phi_{\sigma_1}(F_1) \leq \phi_{\sigma_1}((F_1)_{\text{min}}).
\]
Combined with the fact \( \mu_H(F_1) \geq \mu_H((F_1)_{\text{min}}) \), we have \( \pi_G = \pi((F_1)_{\text{min}}) \in \mathbf{P}_{o\sigma_1}F_1 \). As the triangle \( \mathbf{P}_{o\sigma_1}F_1 \) is lying below the ray \( L_{o\sigma_1}^+ \), we get \( \pi_G \in \mathbf{P}_{o\sigma_1}F_1 \) if \( \mu_H(G) < \frac{c}{r} \). Note that \( \text{rk}(G) \leq \text{rk}(F_1) = r \).

We must have \( \mu_H(G) \geq \frac{c}{r} \) otherwise one will get \( \pi_G \in \Omega_+^v(L_{(o,\sigma_1)}) \) by the same argument in Step 2. It follows that
\[
\mu_H^{-1}(F_1/T) = \mu_H((F_1)_{\text{min}}) = \mu_H(G) \geq \frac{c}{r}.
\]
A similar argument shows \( \mu_H^{-1}(H^{-1}(F_2)) \leq \frac{c-mr}{r} \). This finishes the proof.

**HN-polygon.** Let \( \sigma_{\alpha,0} \) be a stability condition with \( \alpha \) close to \( \sqrt{2/H^2} \). By [11, Proposition 3.4], for fixed \( E \), the HN filtration of \( \sigma_{\alpha,0} \) will stay the same for \( \sqrt{2/H^2} + \epsilon > \alpha > \sqrt{2/H^2} \). Denote by \( \overline{\sigma} \) the limit of \( \sigma_{\alpha,0} \). The ‘stability function’ can be written as
\[
\overline{Z}(E) = r - s + c\sqrt{-1}.
\]
if \( v(E) = (r,c,s) \). Let \( \mathbf{P}_{i,F} \) be the HN polygon\(^1\) for \( i_*F \) with respect to \( \overline{\sigma} \). For \( E \in \mathbf{M}(v) \), we have \( \mathbf{P}_{i_*(E)(c)} = \mathbf{P}_{0123} \), where
\[
z_1 = r - s + c\sqrt{-1} \quad \text{and} \quad z_2 = m(g - 1)(mr - 2c) + mr\sqrt{-1}.
\]
As the polygon \( \mathbf{P}_{i_*(E)(c)} \) only depends on \( v \), we may simply write it as \( \mathbf{P}_v \).

**Theorem 5.3.** For any \( F \in \text{BN}_C(v) \), we have \( \mathbf{P}_{i_*F} \subseteq \mathbf{P}_v \). Moreover, they coincide if and only if \( F = E|_C \) for some \( E \in \mathbf{M}(v) \).

**Proof.** When \( v^2 = 0 \), this is essentially proved in [11, Lemma 4.3]. Let us give a slightly different argument which also works for \( v^2 > 0 \). Suppose the HN-filtration of \( i_*F \) for \( \overline{\sigma} = (\text{Coh}^{\beta = 0}(X), \overline{Z}) \) is given by
\[
0 = \overline{E}_0 \subset \overline{E}_1 \subset \cdots \subset \overline{E}_{l-1} \subset \overline{E}_l = i_*F
\]
with \( E_i := \overline{E}_i/\overline{E}_{i-1} \) the semistable HN-factors. To show \( \mathbf{P}_{i_*F} \subseteq \mathbf{P}_v \), it suffices to show that
\[
\phi_\overline{\sigma}(v) \geq \phi_\overline{\sigma}(E_1) \quad \text{and} \quad \phi_\overline{\sigma}(E_l) \geq \phi_\overline{\sigma}(v(-m))
\]
(see Figure 6b), since \( \mathbf{P}_{i_*F} \) is convex. According to the proof of Proposition 2.2, for any object in \( \text{Coh}^0(X) \), the angle \( \phi_\overline{\sigma} \) in Figure 6b is an increasing function\(^2\) of the angle \( \theta_\overline{\sigma} \) in Figure 6a. Therefore, it is equivalent to show
\[
\theta_\overline{\sigma}(\pi_v) \geq \theta_\overline{\sigma}(\pi_{E_1}) \quad \text{and} \quad \theta_\overline{\sigma}(\pi_{E_l}) \geq \theta_\overline{\sigma}(\pi_{v(-m)})
\]

\(^1\)Here our definition of HN polygon is slightly different from [11, Definition 3.3]. We drop off the part on the right hand side of the line segment \( L_{(0,\overline{\sigma}(F_1))} \).

\(^2\)They are actually equal in this case, as \( \cot \theta_\overline{\sigma} = \frac{m_G}{m_a} = \frac{m_G}{\ln m} = \cot \phi_a \).
Any point $\pi_{E_1}$ in the colored region satisfies
\[
\theta_{\sigma}(\pi_{v(m)}) \leq \theta_{\sigma}(\pi_{E_1}) \leq \theta_{\sigma}(\pi_v)
\]

\[\begin{array}{c}
\text{Figure 6. The angle } \theta_{\sigma} \text{ is equal to the angle } \phi_{\tilde{\sigma}} \\
\end{array}\]

in Figure 6a.

To prove (5.13), consider the sequence
\[
0 \to \tilde{E}_n \xrightarrow{f_n} i_* F \to \cok(f_n) \to 0
\]
for each $\tilde{E}_n$. Since the first wall is not below $L_{\pi_{v(m)},\pi_v}$, we have $\phi_{\sigma_v}(\tilde{E}_n) \leq \phi_{\sigma_v}(i_* F)$. As $\phi_{\tilde{\sigma}}(\tilde{E}_n) \geq \phi_{\sigma_v}(i_* F)$, there exists some stability condition $\sigma \in L_{(\sigma_v,\sigma_v)}$ such that the objects in (5.14) have the same $\sigma$-phase. As a consequence, we have
\[
\pi_{E_1} \in \bigcup_{\sigma \in L_{(\sigma_v,\sigma_v)}} L_{\pi_{v(m)},\pi_v}
\]
(5.15)

Take $n = 1$ and set $v(E_1) = (r', c', s')$. We claim that $\pi_{E_1} \notin P_{\sigma'} \pi_v \pi_v \setminus \{\pi_v\}$ which yields $\theta_{\sigma'}(\pi_{E_1}) \leq \theta_{\sigma'}(\pi_v)$. This can be proved by cases as follows:

Case (1) If $v^2 = 0$, $\pi_{E_1} \notin P_{\sigma'} \pi_v \pi_v \setminus \{\pi_v\}$ automatically holds. This is because $P_{\sigma'} \pi_v \pi_v \setminus \{\pi_v, o'\} \subseteq V(X)$ and (2.2).

Case (2) If $v^2 > 0$ and $r' \leq r$ or $s' \leq s$, as $E_1$ is $\tilde{\sigma}$-semistable, we may assume $v(E_1)^2 \geq -2$ otherwise we may replace $E_1$ by its first JH-factor. According to the Step 1 in Lemma 5.2, we have
\[
v(E_1) \in \Omega_+^\sigma(L_{(\sigma_v,\sigma_v)}).
\]
which contradicts to the assumption $\Omega_+^\sigma(L_{(\sigma_v,\sigma_v)}) \cap H^*_\text{alg}(X) = \emptyset$.

Case (3) If $r' > r$ and $s' > s$, we claim that $r' < r + 1$. Choose a stability condition $\sigma \in L_{(\sigma_v,\sigma_v)}$ such that $\phi_{\sigma_v}(i_* F) = \phi_{\sigma}(E_1)$. Then $v(E_1) \notin \{O, v_{\sigma_v}\}$ is lying in the triangle $P_{O v_{\sigma_v} v_{\sigma_v}}$. This means we have $0 < c' < m r$ and
\[
g(c'')^2 - r's' \geq 0, \quad (c' - m r)^2 - r'(s' + (g - 1)m(r - 2c)) \geq 0.
\]
After reduction, we know that $r' < r + 1$ as $gc^2 - (r + 1)s \leq 0$ and $g(c - m r)^2 - (r + 1)s \leq 0$ by (4.7).

Similarly, take $n = l - 1$ and use the $\sigma$-semistability of $\cok(f_{l-1}) = E_l$, one can prove the second inequality of (5.13).

Finally, if $P_{i_* F} = P_v$, the first wall will coincide with the line $L_{\pi_{v(m)},\pi_v}$ and the last assertion follows from Theorem 5.1.

Remark 5.4. The discussion above can be much more simplified if the following is true: for any $\sigma$ on a wall of $i_* F$, there exists a JH-filtration of $i_* F$ which is convex (i.e., the polygon with vertices $v(\tilde{E}_i)$ is convex in the plane of $P_{O v_{\sigma_v} v_{\sigma_v}}$).
Now we provide a numerical criterion for verifying $P_v = P_{i,v}$ via Euclidean geometry. The key ingredient is the upper bound on the number of global sections of an object $E \in D^b(X)$ established by Feyzbakhsh in \[11, 12\]. Recall that for any $x, y \in \mathbb{Z}$, there is a function
\[
\ell(x + \sqrt{-1}y) := \sqrt{x^2 + 2H^2y^2 + 4(\gcd(x, y))^2}
\]
and one can define $\ell(E) := \sum_i \ell(\mathbb{Z}(E_i))$ where $E_i$’s are the $\sigma$-semistable factors of $E$. Moreover, we have a metric function given by
\[
\|x + \sqrt{-1}y\| := \sqrt{x^2 + (2H^2 + 4)y^2}
\]
and we set $\|E\| := \sum_i \|\mathbb{Z}(E_i)\|$. Clearly, one has $\|E\| \geq \ell(E)$ once the $y$-coordinates are non-zero.

**Proposition 5.5.** [12, Proposition 3.3 and Remark 3.4] Suppose $E \in \text{Coh}^0(X)$ which has no subobject $F \subseteq E$ in $\text{Coh}^0(X)$ with $c_1(F) = 0$, we have
\[
h^0(X, E) \leq \sum_i \left(\frac{\ell(E_i) + \chi(E_i)}{2}\right) = \sum_i \left(\frac{\ell(E_i) - \Re \mathbb{Z}(E_i)}{2}\right),
\]
where $E_i$’s are semistable factors with respect to $\sigma$. In particular,
\[
h^0(X, E) \leq \frac{\|E\| + \chi(E)}{2}.
\]

Following [11], we can give a criterion for the surjectivity of $\psi$.

**Theorem 5.6.** With the notation as in §5.2. Let $z^+_1 = r - s + 1 + c\sqrt{-1}$, $z_1 = r - s - \frac{r - s}{r + s} + (c - 1)\sqrt{-1}$ and $z_2 = r - s - \frac{r - s}{r + s} + (c + 1)\sqrt{-1}$ where $\gamma = \frac{mr}{\ell} - 1$. Assume that
\begin{enumerate}[(i)]
\item $\frac{\ell}{c} + \frac{\gamma - r}{mr - c} \geq 2$
\item $\|z_1 - z_1^+\| - \|z_1^+ - z_1^+\| + \|z_1 - z_2^+\| - \|z_2^+ - z_2\| \geq \frac{2c^2}{r+s} + \frac{2(mr-c)^2}{r+s}$
\end{enumerate}
where $\chi = \chi(c,v) = m(g - 1)(2c - m)$. Then the restriction map $\psi$ will be surjective.

**Proof.** Suppose we have $P_v \neq P_{i,v}$ for some $F \in \text{BN}_C(v)$. By Proposition 5.5 and the convexity, we have
\[
r + s \leq h^0(C, F) = h^0(X, i_v F) \leq \frac{\|i_v F\| + \chi}{2} \leq \frac{h + \chi}{2},
\]
where $h = \sqrt{(r + s - \chi)^2 + 4(mr - c)^2 + (r + s)^2 + 4c^2}$. Then we get
\[
\frac{h + \chi}{2} - (r + s) \geq \frac{h + \chi}{2} - \frac{\|i_v F\| + \chi}{2} = \frac{h - \|i_v F\|}{2}.
\]
However, note that the polygon $P_{0z_1^+z_1z_2^+}$ is convex under the assumption (i), we have
\[
h - \|i_v F\| \geq \|z_1 - z_1^+\| - \|z_1^+ - z_1^+\| + \|z_1 - z_2^+\| - \|z_2^+ - z_2\|.
\]
Combined with assumption (ii), we get
\[
h + \chi - 2(r + s) = \sqrt{(r + s)^2 + 4c^2} - (r + s)
\]
\[
+ \sqrt{(r + s - \chi)^2 + 4(mr - c)^2} - (r + s - \chi)
\]
\[
< \frac{2c^2}{r + s} + \frac{2(mr - c)^2}{r + s - \chi}.
\]
which contradicts to (5.18). This proves the assertion.

\[\diamondsuit\]

As an application, we get an explicit criterion for $\psi$ being surjective for $v^2 \geq 0$.

**Corollary 5.7.** The restriction map $\psi : M(v) \to \text{BN}_C(v)$ is bijective if we further have
\[
g \geq 4r^2 + 1.
\]
Proof. As $r > 1 + \frac{c^2}{2}$, we have

$$s = \left\lfloor \frac{(g - 1)c^2 + 1}{r} \right\rfloor \geq 4rc^2.$$  

This gives

$$s - r \geq 4rc^2 - r \geq 3c$$

(5.22)

as $mr - c > 0$. Moreover, one can compute that

$$\frac{2s - 2r - c}{2s + 2r + c} > \frac{8rc^2 - 2r - c}{8rc^2 + 2r + c} > \frac{6r - 1}{10r + 1} > \frac{1}{r} \geq \frac{4c^2}{s}.$$  

It follows that

$$\|z_1 - z_1^d\| = \sqrt{(s - r)^2 + 4g} - \sqrt{(s - r - 1)^2 + 4g} = \sqrt{(\frac{s - r}{c})^2 + 4g} - \sqrt{(\frac{s - r - 1}{c})^2 + 4g} \geq 0.$$  

The assertion can be concluded from Theorem 5.6.

Remark 5.8. For $g$ sufficiently large, it is not hard to find Mukai vectors satisfying the conditions in Theorem 5.6. For instance, when $v^2 = 0$ and $g > 84$, the Mukai vectors given in [11] and [12] will automatically satisfy the conditions for any $m \geq 1$. However, when $g$ is small, it becomes impossible to find such Mukai vectors.

6. Surjectivity for special Mukai vectors

According to Remark 5.8, Theorem 5.6 does not work well for small $g$. In this section, we develop a way to improve the estimate in §5 for special Mukai vectors of square zero. Let us first introduce the sharpness of the polygon $P_v$.

Definition 6.1. Denote by $z_1^{+d}$ the point $r - s + d + c\sqrt{-1}$. Let $z'_1, z'_2$ be the points as in the Theorem 5.6. We say the polygon $P_v$ is $d$-sharp if for any $P_{i,F} \neq P_v$, one of the following is true:

(i) $P_{i,F}$ is contained in the polygon $P_{0z'_1z'_d,z'_2}$.

(ii) $z_1^{-j}$ is a vertex of $P_{i,F}$ for some $1 \leq j \leq d - 1$.

There is a simple numerical criterion for the $d$-sharpness of $P_v$.

Lemma 6.2. With the notations as before, suppose that

$$\frac{s - r}{c} + \frac{\gamma^2s - r}{\gamma c} \geq 2d$$  

(6.1)

where $\gamma = \frac{nr}{c} - 1$, the polygon $P_v$ will be $d$-sharp.

Proof. From the definition of two polygons, one observes that the interior of $P_v - P_{0z'_1z'_d,z'_2}$ only contains $z_1^{+j}$ ($1 \leq j \leq d - 1$) as integer points. If $P_{0z'_1z'_d,z'_2}$ is convex, then either $P_{i,F}$ is contained in $P_{0z'_1z'_d,z'_2}$ or $z_1^{+j}$ is a vertex of $P_{i,F}$. A little writing reveals the convexity of this polygon literally means (6.1).

The following is an enhancement of Theorem 5.6 for special Mukai vectors.

Theorem 6.3. Suppose $g \geq 3$. Let $v = (g - 1, k, k^2) \in H^*_{\text{alg}}(X)$ be a primitive Mukai vector with $\text{gcd}(g - 1, k) = 1$. Assume that $(m, k)$ satisfies the following three conditions
Then the restriction map $\psi: \mathbf{M}(v) \rightarrow \mathbf{B}\mathbf{N}_{C}(v)$ is surjective.

Proof. By Lemma 6.2, if there is $P_{i,F} \neq P_v$ for some $F$, the polygon $P_v$ will be at least 3-sharp. Therefore, one of the following is true:

(i) $P_{i,F}$ is contained in the polygon $P_{0z_1^3,z_2^3}.$
(ii) $z_1^{+1} = g - k^2 + k\sqrt{1}$ is a vertex of $P_{i,F}.$
(iii) $z_1^{-2} = g + 1 - k^2 + k\sqrt{1}$ is a vertex of $P_{i,F}.$

We will analyse them by cases. Let us first show that case (i) is impossible if $(g,k,m) \neq (5,3,3)$. By (5.18), it suffices to show that

$$h - \|i,F\| > h + \chi - 2(g - 1 + k^2).$$

when $P_{i,F} \subseteq P_{0z_1^3,z_2^3}$. Set $\bar{k} = m(g - 1) - k$. As in the proof of Theorem 5.6, from the convexity and a direct computation, one can get

$$h - \|i,F\| > \|z_1 - z_1^#\| - \|z_1^# - z_1^{-3}\| + \|z_1 - z_2^\ell\| - \|z_2 - z_1^{-3}\|$$

$$= \sqrt{\left(\frac{k^2 - g + 1}{k}\right)^2 + 4g} - \sqrt{\left(\frac{k^2 - g + 1}{k} - 3\right)^2 + 4g}$$

$$+ \sqrt{\left(\frac{k^2 - g + 1}{k}\right)^2 + 4g} - \sqrt{\left(\frac{k^2 - g + 1}{k} - 3\right)^2 + 4g}$$

$$\geq \frac{4\bar{k}^2}{\sqrt{(g - 1 + k^2)^2 + 4k^2} + (g - 1 + k^2)} + \frac{4\bar{k}^2}{\sqrt{(g - 1 + \bar{k})^2 + (g - 1 + \bar{k})}}$$

whenever $(g,k,m) \notin \{(5,3,m),(6,4,3),(8,5,2)\}$ satisfies our assumption.

In the case $(g,k,m) = (6,4,3),(8,5,2)$, or $(5,3,m)$ with $m \geq 4$, though the inequality (6.3) fails, one can give an improvement of the estimate (6.3) by considering the convex hull of integer points in $P_{0z_1^3,z_2^3}$. In those cases, the convex hull is a convex polygon with vertices $z_1,z_1^{-3},z_1^#$, and $z_3$, where $z_3$ is given as below:

- $(g,k,m) = (5,3,m)$, $z_3 = -3 + 2\sqrt{1};$
- $(g,k,m) = (6,4,3)$, $z_3 = -8 + 3\sqrt{1};$
- $(g,k,m) = (8,5,2)$, $z_3 = -14 + 4\sqrt{1}.$

Then one can get

$$h - \|i,F\| > \|z_1\| - \|z_3\| - \|z_3 - z_1^{-3}\| + \|z_1 - z_2^\ell\| - \|z_2 - z_1^{-3}\|$$

A computer calculation of their values shows that (6.2) still holds.

In case (ii) and (iii), if $z_1^{+1}$ or $z_1^{-2}$ is a vertex of $P_{i,F}$, there exists $\tilde{E}_j \subseteq i,F$ in the HN-filtration (5.11) such that $\tilde{Z}(\tilde{E}_j) = z_1^{+1}$ (respectively, $z_1^{-2}$). Then we have

$$\sum_{i}^{\infty} \frac{l(E_i) + \chi(E_i)}{2} \leq \sum_{i \leq j} \frac{l(E_i) + \chi(E_i)}{2} - \frac{\chi(E_i)}{2} + \sum_{i > j} \frac{l(E_i) + \chi(E_i)}{2} - \frac{\chi(E_i)}{2}$$

$$\leq \frac{h + \chi}{2}$$
For simplicity, we may use $\frac{h}{k}$ and $\frac{h}{k}$ to denote the first two terms in the second row. As $h^0(X, i_* F) \geq g - 1 + k^2$, following the argument in Theorem 5.6, it suffices to prove the inequality

$$\frac{h + \chi}{2} - (g - 1 + k^2) < \frac{h - h_1 - h_2}{2},$$

or equivalently,

$$h_1 + h_2 < 2(g - 1 + k^2) - \chi = \|z_1^{+1}\| + \|z_1^{-1} - z_2\| - 2. \quad (6.5)$$

For case ii), a direct computation shows

$$\|z_1^{-1}\| - h_1 = \sum_{i < j} \|E_i\| - h_1 - (\sum_{i < j} \|E_i\| - \|z_1^{+1}\|)$$

$$\geq \sum_{i < j} (\|E_i\| - \ell(E_i)) - (\sum_{i < j} \|E_i\| - \|z_1^{+1}\|)$$

$$\geq (\|E_1\| - \ell(E_1)) - (\sum_{i < j} \|E_i\| - \|z_1^{+1}\|)$$

$$\geq \frac{3}{\sqrt{k^2 + 4g - 3}} - (\sum_{i < j} \|E_i\| - \|z_1^{+1}\|) \quad (6.6)$$

$$\geq \frac{3}{\sqrt{k^2 + 4g - 3}} - (\|z_1^{+1}\| + \|z_1^{-1} - z_1^{+1}\| - \|z_1^{+1}\|) \quad (6.7)$$

$$> 0. \quad (6.8)$$

Let us explain why the inequality (6.6) holds. Note that $Z(E_1) = x + y\sqrt{-1}$ satisfies

$$k^2 - g \leq -\frac{x}{y} \leq k^2 - g + 1.$$

Then we have $-x < ky$ and $y \not| x$ by our assumption $g - 1 \neq k, g \neq k$, and $g < 2k$. This will give

$$\|E_1\| - \ell(E_1) \geq \sqrt{x^2 + 4gy^2} - \sqrt{x^2 + 4(g - 1)y^2 + y^2} \quad (\text{since } y \not| x)$$

$$\geq \frac{3y^2}{2\sqrt{x^2 + (4g - 3)y^2}}$$

$$\geq \frac{3y^2}{2\sqrt{k^2y^2 + (4g - 3)y^2}}$$

$$> \frac{3}{\sqrt{k^2 + 4g - 3}} \quad (\text{since } y \geq 2, \text{ which is a consequence of } y \not| x).$$

The inequality (6.8) holds because

$$\|z_1^{+1} - z_1^{-1}\| + \|z_1^{+1}\| - \|z_1^{+1}\| = \sqrt{\left(\frac{k^2 - (g - 1)}{k}\right)^2} + 4g + (k - 1)\sqrt{\left(\frac{k^2 - (g - 1)}{k}\right)^2} + 4g - (k^2 + g)$$

$$= \sqrt{\left(\frac{k^2 - (g - 1)}{k}\right)^2} + 4g - \left(k - 1 + \frac{g + 1}{k}\right)$$

$$+ (k - 1)\sqrt{\left(\frac{k^2 - (g - 1)}{k}\right)^2} + 4g - \left(\frac{k^2 + g}{k} - (k - 1 + \frac{g + 1}{k}\right)$$

$$\leq \frac{2g(k - 1)}{k^3 - k^2 + (g + 1)k} + \frac{-2g(k - 1)^2}{k^4 - k^3 + (g + 1)k^2 - (g + 1)k}$$

$$= \frac{2g(k - 1)}{(k^2 + g + 1)(k^2 - k + g + 1)}$$

$$\leq \frac{3}{\sqrt{k^2 + 4g - 3}}$$

when $k \geq \frac{g + 1}{2} \geq 2$. Note that $\|z_1^{+1}\| - h_1 = k^2 + g - 2 \sum_{i < j} \frac{\ell(E_i) + \chi(E_i)}{2} - \sum_{i < j} \chi(E_i)$ is an even number, this yields $\|z_1^{+1}\| - h_1 \geq 2$. 
Next, recall that \( \widetilde{E}_i = i_* F \) in the HN filtration (5.11), we can get
\[
\|z_1^{t+1} - z_2\| - h_2 \geq \sum_{i \leq j} (\|E_i\| - \ell(E_i)) \geq \left( \sum_{i \leq j} \|E_i\| - \|z_1^{t+1} - z_2\| \right)
\geq (\|E_1\| - \ell(E_1)) - (\|z_1^{t+1} - z_2\| + \|z_2' - z_2\| - \|z_1^{t+1} - z_2\|)
\geq \frac{3}{\sqrt{k^2 + 4g - 3}} - \frac{2g(k-1)}{(k^2 + g + 1)(k^2 - k + g + 1)} > 0
\]
as \( \tilde{k} > \frac{g+1}{2} \). Combining them together, we can obtain (6.5).

For case (iii), if \( k \nmid g + 1 \), we have
\[
\|z_1^{t+1}\| - h_1 = \sum_{i \leq j} \|E_i\| - h_1 + \|z_1^{t+1}\| - \sum_{i \leq j} \|E_i\|
\geq \|E_1\| - \ell(E_1) + \|z_1^{t+1}\| - \|z_1'\| - \|z_1' - z_1^{t+2}\|
\geq \frac{3}{\sqrt{k^2 + 4g - 3}} + \|z_1^{t+1}\| - \|z_1'\| - \|z_1' - z_1^{t+2}\|
\geq 1
\]
(6.9)

Here, the inequality (6.10) holds because
\[
\|z_1^{t+2} - z_1'\| + \|z_1'\| - \|z_1^{t+1}\| = \sqrt{\frac{(k^2 - (g - 1)k)^2 + 2(4g + (k - 1)\sqrt{k^2 - (g - 1)k})}{k}}
= \sqrt{\frac{k^2 - (g - 1)k}{k} - 2)^2 + 4g - (k - 2 + \frac{g + 1}{k})}
+ (k - 1)\sqrt{\frac{(k^2 - (g - 1)k)^2 + 4g - (k^2 - k + (g + 1) - \frac{g + 1}{k})}{k}} - 1
\leq \frac{2g(2k - 1)}{k(g + (k - 1)^2)} - \frac{2g(k - 1)}{k(g + k^2 + 1)} - 1
= \frac{2g(k^2 + 2k + g - 1)}{(k^2 + g + 1)(k^2 - 2k + g + 1)} - 1
< \frac{3}{\sqrt{k^2 + 4g - 3}} - 1.
\]
Note that \( \|z_1^{t+1}\| - h_1 \) is an odd number, this yields \( \|z_1^{t+1}\| - h_1 \geq 3 \). Similarly, one can get
\[
\|z_1^{t+1} - z_2\| - h_2 \geq 3
\]
under the assumption \( m(g - 1) - k \nmid g + 1 \). Since both of them are at least positive under our assumption, we get (6.5) as well. This finishes the proof for \( (g, k, m) \neq (5, 3, 3) \).

For the remaining case \( (g, k, m) = (5, 3, 3) \), we have to make use of the 4-sharpness of \( P_v \). We just need to verify \( P_{i_* F} \) is not contained in \( P_{0z_1^{t+1}z_2} \) and \( z_1^{t+3} = -2 + 3\sqrt{-1} \) is not a vertex of \( P_{i_* F} \). As above, by using the convex hull of integer points in \( P_{0z_1^{t+1}z_2} \), we have
\[
h - \|i_5 F\| \geq \|z_1\| - || - 3 + 2\sqrt{-1}\| - || - 3 + 2\sqrt{-1} - z_1^{t+4}\| + \|z_1 - z_2'\| - \|z_2' - z_1^{t+1}\|
= -2\sqrt{6} - \sqrt{89} + 2\sqrt{205} + \frac{\sqrt{7549}}{9} - \frac{\sqrt{3301}}{9}
> h + \chi - 2(g - 1 + k^2).
\]
which show that \( P_{i_* F} \) cannot lie in \( P_{0z_1^{t+1}z_2} \). Moreover, a similar estimate of \( \|E_1\| - \ell(E_1) \) and \( \|E_1\| - \ell(E_i) \) in (ii) and (iii) shows that \( z_1^{t+3} \) is not a vertex of \( P_{i_* F} \).

\textbf{Remark 6.4.} One can also directly check the small genera cases by running the computer program in [12, Section 4].
7. Surjectivity of the tangent map

In this section, we adapt Feyzbakhsh’s approach to study the surjectivity of the tangent map and obtain a sufficient condition for the restriction map being an isomorphism.

**Theorem 7.1.** Let \( v = (r, c, s) \in H^1_{\text{alg}}(X) \) be a Mukai vector satisfying (4.6) and (4.7). The morphism
\[
\psi : \mathbf{M}(v) \to \mathbf{BN}_C(v)
\]
is an isomorphism whenever the following conditions hold

(i) \( \psi \) is surjective;
(ii) \( h^0(X, E) = r + s \) for any \( E \in \mathbf{M}(v) \);
(iii) there exists \( \sigma \in \mathbf{L}(\pi_{v(-m)}, \pi_{vK}) \cap \mathbf{V}(X) \) such that
\[
\Omega^+_{\pi_{v(-m)}}(L(o, \sigma)) \cap H^*_{\text{alg}}(X) = \Omega^+_{vK}(L(o, \sigma)) \cap H^*_{\text{alg}}(X) = \emptyset,
\]
where \( v_K = (s, -c, r) \);
(iv) \( 2s > v^2 + 2c^2 \), or \( 2s > v^2 + 2 \) and \( \gcd(c, s) = 1 \).

**Proof.** As \( \psi \) is bijective, it suffices to show the tangent map \( d\psi \) is surjective. The argument is similar as [11, §6]. For the convenience of readers, we sketch the proof as below. For any \( E \in \mathbf{M}(v) \), the differential map \( d\psi : T_E[\mathbf{M}(v)] \to T_{[E][\mathbf{C}]\mathbf{BN}_C(v)} \) at \([E]\) can be identified as the map
\[
d\psi : \text{Hom}(E, E[1]) \to \ker(\text{Hom}_C(E[1], C[1]) \to \text{Hom}(H^0(C, E[1]), H^1(C, E[1]))
\]
sending \((E \to E[1])\) to \((E[1] \to E[1][1])\).

Let \( \xi : E[1] \to E[1][1] \) be a Mukai vector in \( T_{[E][\mathbf{C}]\mathbf{BN}_C(v)} \). Then Feyzbakhsh has shown in [11, §6] that there exist morphisms \( \xi' \) and \( \xi'' \) such that the following commutative diagram holds
\[
\begin{array}{ccc}
E & \xrightarrow{i_*} & E[1] \\
\downarrow{\exists \xi'} & & \downarrow{\xi'} \\
\downarrow{i_\xi} & & \downarrow{\xi''} \\
E[1] & \xrightarrow{i_*} & E[1][1]
\end{array}
\]
provided that
\[
K_E = M[1] \quad \text{and} \quad \text{Hom}_X(M, E(-C)[1]) = 0
\]
where \( K_E \) is the cone of the evaluation map \( O^{\mathcal{O}^0_{X}(X,E)}_X \to K_E \) in \( D^b(X) \). Note that \( d\psi(\xi') = \xi \), we are therefore reduced to check (7.2) holds for every \( E \).

Note that \( v(K_E) = -v_K \) and \( \pi_{vK} = \pi_{K_E} \). We can choose the stability condition \( \sigma_1 \in L(\pi_{vK}, o') \) sufficiently close to \( o' \) and \( \sigma_2 \in L(\pi_{K_E}, o) \) sufficiently close to \( o \) so that
\[
\text{P}_{\sigma_2\sigma_1o'} \setminus \{o, o'\} \subseteq \text{P}_{\sigma vK} \cap \Gamma \subseteq \mathbf{V}(X),
\]
see Figure 7. As in the proof of Theorem 4.1, we have \( O_X \) and \( E \) are \( \sigma_1 \)-semistable of the same phase. Then as the quotient of \( E \) by \( O_X^{\mathcal{O}^0_{X}(X,E)} \), \( K_E \) is also \( \sigma_1 \)-semistable of the same \( \sigma_1 \)-phase. Note that Lemma 4.2 still holds if we exchange \( r \) and \( s \) in Mukai vector \( v \). Then we get
\[
\Omega^+_{vK}(\text{P}_{\sigma vK} \cap \Gamma) \cap H^*_{\text{alg}}(X) = \emptyset.
\]
Since \( v_K \) is primitive, we have \( \Omega^+_{vK}(\text{P}_{\sigma vK} \cap \Gamma) \cap H^*_{\text{alg}}(X) = \emptyset \). By Proposition 3.4, \( v_K \) admits no strictly semistable stability conditions in \( \text{P}_{\sigma_2\sigma_1o'} \setminus \{o, o'\} \). Therefore, \( K_E \) is stable for any \( \tau \in \text{P}_{\sigma_2\sigma_1o'} \setminus \{o, o'\} \). This implies that \( K_E \) is \( \sigma_2, 0 \)-stable for \( \alpha > \left( \frac{1}{r} \right)^2 \). By [14, Lemma 6.18], we have \( H^{-1}(K_E) \) is a \( \mu_H \)-semistable torsion free sheaf and \( H^0(K_E) \) is a torsion sheaf supported in dimension zero. So we can set \( v(H^0(K_E)) = (0, 0, a) \) and \( v(H^{-1}(K_E)) = (s, -c, r + a) \) for some \( a \geq 0 \). By [11, Lemma 3.1], we have
\[
-2c^2 \leq v(H^{-1}(K_E))^2 = v^2 - 2sa.
\]
When \( \gcd(c, s) = 1 \), we have \( H^{-1}(K_E) \) is slope stable and \( v(H^{-1}(K_E))^2 \geq -2 \). Then by condition (iv), we have \( a = 0 \) and \( H^0(K_E) = 0 \). So we obtain \( K_E = M[1] \), where \( M = H^{-1}(K_E) \) is a \( \mu_H \)-semistable torsion free sheaf.

Since \( \Omega^*_\nu(X) \cap H^*_{\text{alg}}(X) = \emptyset \), \( v(M) \) admits no strictly semistable condition in \( L_{(o, \sigma)} \). It follows that \( M \) is \( \sigma \)-stable as it is \( \sigma_2 \)-stable. Similarly, we have \( E(-C)[1] \) is also \( \sigma \)-stable. Since \( M \) and \( E(-C)[1] \) are \( \sigma \)-stable of the same phase, one must have \( \text{Hom}_X(M, E(-C)[1]) = 0 \). This proves the assertion.

\[ \blacksquare \]

**Figure 7**

As a first application, we obtain a numerical criterion for Mukai’s program.

**Theorem 7.2.** Assume \( g > 2 \). Let \( v = (r, c, ck) \in H^*_{\text{alg}}(X) \) be a primitive Mukai vector with \( v^2 = 0 \) and \( \gcd(r, c) = 1 \). Suppose that

\[ r | g - 1, \quad k \leq 9 \quad \text{and} \quad m > 1 + \frac{ck}{r(k - 1)}. \]

The restriction map \( \psi : M(v) \to BN_C(v) \) is an isomorphism if it is a surjective morphism.

**Proof.** Let us check that the conditions (ii)-(iv) in Theorem 7.1 are satisfied. By our assumption, we know that \( \gcd(r - s, c) = 1 \). According to [12, Lemma 3.1], one has

\[ h^0(X, E) \leq r + s, \]

which forces \( h^0(X, E) = r + s \) by (4.2). This verifies the condition (ii).

For the condition (iv), note that we have \( s = \frac{c^2(g - 1)}{r} \geq c^2 \) where the equality holds when \( r = g - 1 \).

If \( r = g - 1 \), the inequality in (7.3) will be equality. By [11, lemma 3.1], we have \( c | (g - 1) \) which is a contradiction. Thus we only need to verify the condition (iii). By Remark 3.5, it suffices to show

\[ P_{o \sigma v \pi v(-m)} \backslash \{ \text{vertices} \} \subseteq V(X). \]

To make the computation easier, we may consider the action of tensoring the invertible sheaf \( \mathcal{O}_X(H) \) which sends the triangle \( P_{o \sigma v \pi v(-m)} \) to the triangle \( P_{o p_1 p_2} \), where \( p_1 = \pi_{v(1)} \) and \( p_2 = \pi_{v(1-m)}. \)

Then it is equivalent to show there are no projection of roots in \( P_{o p_1 p_2} - \{ \text{vertices} \} \).

Firstly, we show that there is no projection of root on the two edges joining \( o \). By definition, we have

\[ p_1 = \left( \frac{k^r}{(k-1)r}, \frac{c^r}{(k-1)r} \right) \quad \text{and} \quad p_2 = \left( \frac{c^r}{k((m-1)r-c)}, \frac{c^r}{k(c-(m-1)r)} \right). \]

Then two open edges \( L_{(o, p_1)} \) and \( L_{(o, p_2)} \) do not contain any projection of roots by Observation (B).

Next, since \( (m-1)r > \frac{ck}{(k-1)} > c \), we know that \( p_1 \) is lying in the first quadrant while projection \( p_2 \) is lying in the second quadrant. So the region

\[ P_{o p_1 p_2} \backslash (L_{(o, p_1)} \cup L_{(o, p_2)}) \]
Moreover, if there is a root $\delta = (r', c', s') \in R(X)$ with $r' > 0$ whose projection $\pi_\delta$ is lying in $P^o_{op2,\infty}$, one can follow the computation in Lemma 4.2 to get inequalities

$$kc' < (k-1)r' < kc' + \frac{k}{(g-1)c'}$$

(7.4)

However, one can directly check that there are no such integers $(r', c', s')$ satisfying (7.4) under the assumption $k \leq g - 1$ or $3 < k \leq 3g - 3$.

It remains to show that $P_{op1,2} \cap y$-axis $\subseteq V(X)$. Note that

$$L_{[p,1, p, 2]} \cap x$-axis $= (\frac{c/(k-1)}{(m-1)r-c}, 0)$$

which is below $\alpha'$. It follows that $P_{op1,2} \cap y$-axis $\subseteq L_{(\alpha, \alpha')} \subseteq V(X)$.

Moreover, we can reconstruct hyperkähler varieties as Brill–Noether locus for Mukai vectors given in Corollary 5.7.

**Theorem 7.3.** Under the assumptions in Corollary 5.7, the restriction map $\psi : M(v) \to BN_C(v)$ is an isomorphism.

**Proof.** As above, we only need to verify the conditions (ii)-(iv) in Theorem 7.1. We will check them one by one.

(1) Let us first verify that $h^0(X, E) = r + s$ for any $E \in M(v)$. By [12, Proposition 3.1], it suffices to show that

$$\sqrt{(r-s)^2 + (2g+2)c^2} < \frac{r+s}{2} + 1$$

(7.5)

After simplification, one can find that (7.5) is equivalent to

$$\frac{(g+1)c^2 - 1}{2r+2} - 1 < s.$$

This holds when $(g-1)c^2 - rs < r$ and $g > 4r^2 + 1$.

(2) For condition (ii), we claim that

$$L_{(\pi_{v(-m)}, \pi_{vK})} \cap \Gamma \neq \emptyset,$$

and hence $L_{(\pi_{v(-m)}, \pi_{vK})} \cap V(X) \neq \emptyset$. Let us write $v(-m) = (r, \tilde{c}, \tilde{s})$ and $v_K = (s, -c, r)$ with $\tilde{c} = c - mr$ and $\tilde{s} = \lfloor (g-1)c^2 + 1 \rfloor$. Then we only need to show that the quadratic equation

$$g((1-t)t\tilde{c} + t(-c))^2 = ((1-t)r + ts)((1-t)\tilde{s} + tr)$$

(7.6)

has roots for $0 < t < 1$. By calculating the discriminant of (7.6), we know it has a solution $t_0$ satisfying

$$0 < t_0 < \frac{\tilde{c}^2g - r\tilde{s}}{s\tilde{s} + r^2 + 2\tilde{c}cg + 2(c^2g - r\tilde{s})} < 1.$$  

(7.7)

(3) Choose $\sigma \in L_{(\pi_{v(-m)}, \pi_{vK})} \cap \Gamma$, we first verify that

$$\Omega^+_{v(-m)}(L_{(\sigma, \sigma)}) \cap H_{alg}^*(X) = \emptyset.$$  

Suppose there is an integer point $p_0 = (x_0, y_0, z_0) \in \Omega^+_{v(-m)}(L_{(\sigma, \sigma)})$. By Lemma 7.1, we have

$$\tilde{c} - 1 < y_0 < 0.$$  

Moreover, one may observe that $p_0$ is lying in a (closed) planar region enclosed by the conic

$$Q = \{ y = y_0, (g - 1)y^2 + 1 = xz \}$$
Lemma 7.4. For any integer point \( (x_0, y_0, z_0) \in \Omega^+_{v(-m)}(L_{(o,a)}) \) in Theorem 7.3, we have
\[
\tilde{c} - 1 < y_0 < 0
\]

Proof. Set \( u_t = (1 - t)v(-m) + tv_K \). Let \( 0 < t_0 < t_1 < 1 \) be the roots of equation (7.6). We set
\[
w = (x', y', z') = L_{O,v_0} \cap L_{v(-m),v(-m)+v_1}.
\]

Then \( \Omega^+_{v(-m)}(L_{(o,a)}) \) is contained in the tetrahedron \( T_{Ov(-m)\omega w} \) with 4 vertices \( O, v(-m), w \) and \( \omega = (r, \tilde{c}, \frac{ge_2}{r}) \). This gives \( y' < y_0 < 0 \). Hence we only need to estimate the lower bound of \( y' \).

Set \( v_{t_0} = (r_{t_0}, c_{t_0}, s_{t_0}) \), then we have \( w = \frac{1}{c_{t_0}}v_{t_0} \in L_{o,v_0} \). Note that \( w - v(-m) \in L_{O,v_1} \) is lying on the hyperboloid
\[
\left\{ (x, y, z) \in \mathbb{R}^3 \mid gy^2 - xz = 0 \right\}.
\]

Then one can see that \( y' < \tilde{c} - 1 \) if
\[
\frac{\tilde{c} - 1}{c_{t_0}}v_{t_0} - v(-m) \in \left\{ (x, y, z) \in \mathbb{R}^3 \mid gy^2 - xz < 0 \right\},
\]
i.e.
\[
\left( \frac{\tilde{c} - 1}{c_{t_0}}r_{t_0} - r \right) \left( \frac{\tilde{c} - 1}{c_{t_0}}s_{t_0} - \tilde{s} \right) > g.
\]
Plugging the coordinates of \( v_0 \) into (7.11) and simplify all the terms, one can obtain a quadratic inequality of \( t_0 \) and one can easily see that (7.11) holds if

\[
t_0 < \frac{(2 - \tilde{c})(\tilde{c}^2 g - r\tilde{s})}{\tilde{c}[r\tilde{s} - r^2 - s\tilde{s} + (2 - \tilde{c})g(c + \tilde{c})] + r^2 + s\tilde{s} - (c + 2)r\tilde{s}}.
\]

Using the upper bound of \( t_0 \) given in (7.7), we are reduced to check

\[
\tilde{c}(r\tilde{s} - r^2 - s\tilde{s} + (2 - \tilde{c})g(c + \tilde{c})) + r^2 + s\tilde{s} - (c + 2)r\tilde{s} < (2 - \tilde{c})(s\tilde{s} + r^2 - 2r\tilde{s} + 2\tilde{c}g(\tilde{c} + c)).
\]

After further simplification and reduction, the inequality above becomes

\[
0 < s\tilde{s} + r^2 + 2\tilde{c}g + c - (\tilde{c} + c - 2)(\tilde{c}^2 g - r\tilde{s}) \tag{7.12}
\]

The right hand side can be estimated as below

\[
\text{RHS} > r^2 + s\tilde{s} + 2\tilde{c}g - (\tilde{c} + c - 2)(\tilde{c}^2 g - r\tilde{s})
\]

\[
= r^2 + s\tilde{s} + 2\tilde{c}g + (mr + 2 - 2c)\left(\tilde{c}^2 + \frac{v^2}{2}\right)
\]

\[
> r^2 + s\tilde{s} + 2\tilde{c}g - r(\tilde{c}^2 + r) \tag{7.13}
\]

\[
\geq \left(\frac{(g - 1)c^2}{r} - 1\right)\left(\frac{(g - 1)c^2}{r} - 1\right) + 2\tilde{c}g - r\tilde{c}^2
\]

\[
> 0.
\]

\[\blacklozenge\]

8. Proof of the main theorems

Let us first prove Theorem 1.1. As the case of \( m = 1 \) is already known, we may always assume \( m > 1 \). There will be two cases:

(i) If \( (g, m) \neq (7, 2) \), we can choose the Mukai vector \( v = (g - 1, k, k^2) \) with \( k \) given in the Table below:

| Values of \( g \) | Values of \( k \) | Range of \( m \) |
|------------------|-----------------|----------------|
| 3                | \( k = 5 \)     | \( m \geq 5 \) |
| 4                | \( k = 5 \)     | \( m \geq 4 \) |
| 5                | \( k = 3 \)     | \( m \geq 3 \) |
| 6                | \( k = 4 \)     | \( m \geq 3 \) |
| 7                | \( k = 5 \)     | \( m \geq 3 \) |
| \( \geq 8 \)     | \( k = \min\{k_0 \mid k_0 > \frac{g}{2}, \gcd(g - 1, k_0) = 1\} \) | \( m \geq 2 \) |

Table 1. Choices of Mukai vectors

Note that when \( g \geq 8 \), we have

\[
\min\left\{k_0 \mid k_0 > \frac{g}{2}, \gcd(g - 1, k_0) = 1\right\} < g - 2.
\]

By a direct computation, one can easily see that the values of \( k \) and \( m \) in Table 1 satisfy the conditions in Theorem 6.3 and Theorem 7.2.

(ii) If \( (g, m) = (7, 2) \), Theorem 6.3 fails for all primitive Mukai vectors of the form \( (6, k, k^2) \). However, we can choose \( v = (2, 1, 3) \) and the assertion can be concluded by the following result.

Proposition 8.1. Suppose \( g = 7 \). The restriction map \( \psi : M(2, 1, 3) \rightarrow BN_C(2, 1, 3) \) is an isomorphism for any irreducible curve \( C \in |2H| \).
Proof. Note that $v$ satisfies the hypothesis in Corollary 4.3, we know that $ψ$ is an injective morphism with stable image. Due to Theorem 7.2, it suffices to show that $ψ$ is surjective. Suppose $P_v \neq P_{i,F}$ for some $F \in \text{BN}_C(v)$. A direct computation shows $P_v$ is at least 2-sharp. Then either $P_{i,F}$ lies inside the polygon $P_{0z_1^{-1}z_2^{-1}z_3^{-2}}$, or it has $z_1^{-1}$ as a vertex. For the first case, one has

\[
\begin{align*}
&h - \|i_sF\| > \|z_1 - z_1'\| - \|z_1' - z_1^{-2}\| + \|z_1 - z_2'\| - \|z_2' - z_1^{-2}\| \\
&= \frac{\sqrt{277}}{3} - \frac{\sqrt{613}}{3} \\
&> \sqrt{29} + \sqrt{277} - 34 = h + \chi - 10
\end{align*}
\]

which contradicts to (5.18). For the second case, it forces $\mathbb{Z}(\tilde{E}_1) = z_1^{-1}$ and hence

\[
5 \leq h^0(C,F) = h^0(X,i_sF) \leq \left\lfloor \frac{\ell(z_1^{-1})}{2} \right\rfloor + \frac{\|z_1^{-1} - z_2'\| + \|z_2' - z_2\| + \chi}{2} \leq \frac{h + \chi}{2}.
\]

However, we have

\[
\begin{align*}
\frac{h - (\|z_1^{-1} - z_2'\| + \|z_2' - z_2\|)}{2} - \frac{\ell(z_1^{-1})}{2} &= \frac{1}{6} \left( \sqrt{277} - 4 \sqrt{46} \right) - 1 \\
&\geq \frac{1}{2} \left( \sqrt{29} + \sqrt{277} - 34 \right) \\
&= \frac{h + \chi}{2} - 5
\end{align*}
\]

which is impossible. It follows from Theorem 5.3 that $ψ$ is surjective. ♣

Now we prove Theorem 1.2. As in the proof of Theorem 1.1, for each $n > 0$, we need to find Mukai vectors $v$ with $v^2 = 2n$ satisfying the assumptions in Corollary 5.7. A key tool is

**Lemma 8.2.** For each $n$, there is an integer $N = N(n)$ such that for $g > N$, one can find a prime number $p$ satisfying that

(i) $n + 1 < p < \sqrt{\frac{g-1}{2}}$

(ii) the equation $x^2 \equiv (g-1)n \mod p$ has a solution.

**Proof.** The idea is to use the bound for prime character nonresidues. In [18, Theorem 1.4], it has been proved that there exists an integer $m_0$ with the property: if $j > j_0$ and $\chi$ is a quadratic character modulo $j$, there are at least $\log(j)$ primes $\ell \leq \sqrt{j}$ with $\chi(\ell) = 1$. Choose $N$ to be the minimal integer satisfying

- $8(N-1)n \geq j_0$,
- the $|\log(8(N-1)n)|$-th prime number $> n + 1$,
- $\sqrt[8]{8(N-1)n} \leq \frac{\sqrt[8]{g-1}}{2}$.

Clearly, it only depends on $n$. For $g > N$, we write

\[
g(n-1) = a^2 \prod_{i=1}^{k} q_i,
\]

where $q_i$ are distinct primes. Let $\chi_i$ be the character defined by

\[
\chi_i(d) = \left( \frac{d}{q_i} \right) (-1)^{\frac{(d-1)(q_i-1)}{4}}
\]

if $q_i$ is odd and $\chi_i(d) = (-1)^{\frac{d^2 - 1}{4}}$ if $q_i = 2$. Consider the quadratic character

\[
\chi(d) = \prod_{i=1}^{k} \chi_i(d)
\]

modulo $8(g-1)n$. As $8(g-1)n > N \geq j_0$, there exists a prime $p$ such that $\chi(p) = 1$ and

\[
n + 1 < p < \sqrt[8]{8(g-1)n} \leq \frac{\sqrt[8]{g-1}}{2}.
\]
Then we have its Jacobi symbol is
\[
\left( \frac{g(n-1)}{p} \right) = \prod_{i=1}^{k} \left( \frac{q_i}{p} \right) = \prod_{i=1}^{k} \chi_i(p) = \chi(p) = 1
\]
by the law of reciprocity. It follows that \(x^2 = g(n-1) \mod p\) has a solution.

Due to Lemma 8.2, when \(g > N(n)\), we can find an odd prime \(p\) and an integer \(0 < c < p\) satisfying
\[
n + 1 < p < \sqrt{2g - 1} \quad \text{and} \quad p \mid c^2(g-1) - n.
\]
Choose the Mukai vector \(v = (p,c,\frac{c^2(g-1)-n}{p})\), it automatically satisfies all assumptions in Corollary 5.7. The assertion then follows immediately.
