Abstract

Under the assumption of a CSW generalization to loop amplitudes in $\mathcal{N} = 4$ SYM,
1. We prove that, formally the S-matrix is superconformal invariant to any loop order, and
2. We argue that superconformal symmetry survives regularization. More precisely, IR safe
quantities constructed from the S-matrix are superconformal covariant. The IR divergences
are regularized in a new holomorphic anomaly friendly regularization.

The CSW prescription is known to be valid for all tree level amplitudes and for one loop MHV
amplitudes. In these cases, our formal results do not rely on any assumptions.

1 Introduction and Discussion

Symmetry has proved to be of utmost importance in unveiling the remarkable beauty hidden in $\mathcal{N} = 4$ super Yang-Mills. Two examples illustrate this rather nicely:

1. The study of the planar spectrum of this gauge theory is mapped to the study of an integrable model [1]. Particle excitations in this model transform under an extended $SU(2|2)$ symmetry algebra which completely constrains the 2-body S-matrix [2], the main ingredient in the computation of the exact spectrum of the theory.1

2. A second example, closely related to the subject of this paper, concerns planar scattering amplitudes in $\mathcal{N} = 4$ SYM. Both at weak and strong coupling, these amplitudes possess an anomalous *dual conformal symmetry* [6, 7, 8, 9, 17]. For 4 and 5 particles, this anomalous symmetry fixes the form of the Maximally Helicity Violating (MHV) amplitudes at any value of the t’ Hooft coupling in terms of the cusp anomalous dimension [7] which can be computed from Integrability [4]. For more than 5 particles, this symmetry is still very constraining. It fixes the form of the MHV planar amplitudes to be given by the BDS ansatz [10] times a reminder function that depend only on the dual conformal cross-ratios and become trivial in collinear limits. Surprisingly, it is the mysterious dual superconformal symmetry that is under control at loop level whereas the usual superconformal symmetry is understood at tree level only [11, 12, 13, 15].

There seems to be two deep connections between these two points. First, the usual conformal symmetry as well as the dual conformal symmetry of $\mathcal{N} = 4$ SYM form a Yangian [16, 17, 18, 12] – the structure of higher charges arising in integrable models. Second, as emphasized in [13], the superconformal generators which act on the generating function of scattering amplitudes, are expected to share many features with the length changing higher charges that acts on a single trace operators. These appear in the context of computing the planar spectrum of the theory. The possibility of making such nice connections precise in the future, as well as the remarkable success observed so far, entitles us to big expectations.

At tree level, partial scattering amplitudes were shown to be invariant under superconformal transformations [19, 12]. However, due to the so called holomorphic anomaly [20], superconformal transformations fail to annihilate the tree level amplitudes whenever two adjacent momenta become collinear. As was shown in [13], that failure can be corrected by adding a term to the superconformal generators that split one massless particle into two collinear ones. As we will show in this paper, already at tree level, there are additional points in phase space where superconformal transformations fail to annihilate a tree level amplitude. E.g., the points where the amplitude factorize on a multi-particle pole and, in addition, the on-shell internal momenta become collinear to one of the external momenta. At these points, the failure can be corrected by adding a term to the superconformal generators that at tree level, join two disconnected amplitude with a shared collinear momenta into a single connected amplitude. The resulting symmetry is therefore not a symmetry of an individual amplitude but instead, a symmetry of the tree level S-matrix. That correction of the tree level generators might seem like a picky detail – after all, for generic momenta, the tree level amplitudes are indeed symmetric. However, at loop level this detail becomes of major

---

1In an integrable theory, finding the S-matrix is the main step towards the computation of the exact spectrum which follows a (not completely) standard recipe [3], carried out in the AdS/CFT context in [1, 2, 4, 5] and references therein.
importance. The reason is that internal loop momenta scan over all phase space and in particular on the points were they become collinear to an external momenta. As a result, the superconformal generators fails to annihilate any loop amplitude. That is clearly not a picky detail!

Further complication of loop amplitudes over tree level ones is the presence of IR divergences and the resulting need for regularization. These IR divergences arise from the region of integration where an internal momenta become collinear to an external one. Therefore, the IR divergences and the failure of superconformal invariance are closely related.

The goal of this paper is to promote the superconformal symmetry to loop level. We will assume that the MHV diagrammatic expansion \([20]\) holds at any loop order, which although very plausible was only checked in the literature to one loop \([21]\). Under that assumption, we will find a correction to the generators that annihilate the full S-matrix.

The analysis will first be done without a regulator. Such analysis is only formal because \(\mathcal{N} = 4\) YM is conformal and therefore don’t have asymptotic particles. As a result, the probability for scattering some fixed number of massless particles into another fixed number of massless particles is zero. Technically, the corresponding perturbative analysis is plagued with IR divergences. The S-matrix is however non-trivial by means that there are physical observables constructed from the would have been S-matrix. These are IR safe quantities such as inclusive cross sections\(^2\). In perturbation theory, the only known way to construct these observables is from the S-matrix elements which, for massless particles, are not good observables.\(^3\) To overcome that problem, one first introduces an IR regulator. The resulting IR regulated theory has an S-matrix from which the desired observables are computed. A good IR regulator is a regulator that drops out of IR safe physical quantities leaving a consistent answer behind. We will argue that these physical observables are superconformal covariant. That is, we will show that no violation of superconformal invariance emerges from their (regulated) S-matrix elements building blocks.

A similar issue arises in the study of dual conformal invariance of planar amplitudes. In analogy to conformal symmetry, there, loop amplitudes are formally dual conformal covariant. However, any regularization result in a dual conformal anomaly \([7, 24]\). The anomaly however, can be recast as a correction to the dual conformal generators such that they act on the regulator.\(^4\) In other words, the corrected generators are anomaly free. Planar IR safe quantities are therefore dual superconformal covariant as no violation of dual conformal invariance arises from their S-matrix elements building blocks.

The situation with conformal transformations is more involved. The reason is that the terms in the superconformal generators that, at tree level, join two disconnected amplitudes can also act on a connected part of an amplitude. When they do, a new loop is formed within the connected amplitude. It is therefore not enough for regulate the amplitudes but we must also regulate the superconformal generators.

\(^2\)These usually involve an external probe. See \([23]\) for a recent study of these in \(\mathcal{N} = 4\) SYM.

\(^3\)Ideally, one would like to have an alternative formulation of physical IR safe observables that do not pass through the IR unsafe S-matrix. Identifying these observables in the T-dual variables \([9]\) may help in finding such formulation.

\(^4\)As far as we know, that point was not illustrated in the literature. We have checked that explicitly in two different regularizations. One, is the regularization in which the external particles are given a small mass. The other, is the Alday-Maldacena regularization \([9]\) where scattered particles are charged under a small gauge group on the Coulomb branch of the large \(N\) one. Note added to this footnote: As this paper was being completed the work \([25]\) appeared where this scenario was checked at one loop in the Coulomb Branch regularization, see \([26]\) for a related discussion at strong coupling.
In the last section, we will regulate the amplitudes and repeat the calculation, now identifying a regularized form of the generators. The calculation will be done in a new regularization in which the external particles are given a small mass. The regulated amplitude is then computed using the CSW prescription, now treating the external particle in the same way as the internal ones. We expect that planar dual-conformal invariance can be proved to all orders in perturbation theory using the same techniques.

The paper is organized as follows: In section 2 we review the superconformal invariance of tree level amplitudes [12, 13]. In section 3 we find the unregularized form of the generators by demanding that they annihilate finite unitarity cuts of the MHV one loop generating function. In section 4 we show that the generators found in section 3 formally annihilate the unregularized one loop MHV generating function. In section 5 we use the tree level results and a conjectured loop level CSW generalization to formally derive the superconformal invariance of the full S-matrix at any loop order. In section 6 we will propose a new "holomorphic anomaly friendly" regularization named sub MHV regularization. It will allow us to keep the symmetry, found in the previous sections, under control and read of a regularized form of the generators. Appendix A contains some technical details relevant to section 4.

2 Superconformal Invariance of Tree Level Amplitudes

This section is a quick review of partial tree level partial scattering amplitudes in $\mathcal{N} = 4$ SYM, their generating function and superconformal invariance. We assume the reader is familiar with the spinor helicity formalism and only set notation and highlight a few essential points.

On-shell states in $\mathcal{N} = 4$ are most conveniently represented in spinor helicity superspace. The light-like momenta is decomposed into a product of a positive chirality spinor $\lambda^a$ and a negative chirality spinor $\bar{\lambda}^\dot{a}$ through $k^{a\dot{a}} = \lambda^a \bar{\lambda}^{\dot{a}} = s \lambda^0 \bar{\lambda}^0$. Here $\bar{\lambda} = (\lambda)^* = s \lambda$ and $s$ is the energy sign of $k$. We will work in $(+, -, -, -)$ signature so that $s = \text{sign}(k^0) = \text{sign}(k_0)$. In superspace, the scattering amplitude of $n$ particles is a function $A_n(\lambda_1, \bar{\lambda}_{\dot{1}}, \eta_1, \ldots, \lambda_n, \bar{\lambda}_{\dot{n}}, \eta_n)$, where in our convention all particles are out-going and $\eta^A, A = 1, \ldots, 4$ is a superspace coordinate transforming in the fundamental representation of the $SU(4)$ R-symmetry. Amplitudes can be classified by their helicity charge

$$h(n, k) = 2n - 4k.$$  

Here the number $k$ counts the number of $\eta$'s. It ranges between 8 for MHV amplitudes and $4n - 8$ for MHV amplitudes. The MHV partial amplitudes take the simple form [14]

$$A_n^{(0)} \text{MHV}(1, 2, \ldots, n) = \delta^4(P_n) A_n^{(0)} \text{MHV}(1, 2, \ldots, n) = i \frac{\delta^8(Q_n) \delta^4(P_n)}{(12)(23)\ldots(n1)},$$

where $P_n = \sum_{j=1}^n k_j$ and $Q_n = \sum_{j=1}^n \lambda_j^0 \bar{\eta}_j^\dot{0}$. Here, for keep notations simple, we omitted a factor of $g^{n-2}(2\pi)^4$. The dependence on the YM coupling $g$ will be restored below when defining the generating functional whereas, the $(2\pi)^4$ factor is systematically removed from vertices and propagators in our conventions. The superconformal generators that will be most relevant for us are the special
conformal generator and its fermionic counterparts, the special conformal supercharges\(^5\)

\[ S_{aA} = \sum_{i=1}^{n} \frac{\partial}{\partial \lambda^i} \eta^i \, \partial, \quad \bar{S}^A = \sum_{i=1}^{n} \eta^i \frac{\partial}{\partial \lambda^i} \, \partial, \quad K_{\dot{a}A} = \sum_{i=1}^{n} \frac{\partial}{\partial \lambda^i} \frac{\partial}{\partial \bar{\lambda}^i} \, \partial. \]  

(3)

They satisfy the commutation relation

\[ \{ S_{aA}, \bar{S}^B \dot{a} \} = \delta^B_A K_{\dot{a}A}. \]  

(4)

Furthermore, the \( S \) generator can be obtained from \( \bar{S} \) by conjugation. For this reason, in the next sections, we will mostly focus on the special conformal supercharge \( \bar{S} \).

The superconformal generators annihilate all tree level amplitudes provided the external momenta are generic \([19, 12]\). However, due to the presence of the so-called holomorphic anomaly \([20]\)

\[ \frac{\partial}{\partial \lambda^a} \frac{1}{\langle \lambda, \mu \rangle} = \pi \bar{\mu}_a \delta^2(\langle \lambda, \mu \rangle) \]  

(5)

the action of the generators (3) on the tree level amplitude results in extra terms supported at the points in phase space where two adjacent momenta are collinear. At these points, the generators (3) fail to annihilate an individual tree level amplitude. Physically, the reason is that two on-shell collinear massless particles and a single particle carrying their momenta and quantum numbers are undistinguishable and are mixed by the generators (3). Therefore, a more suitable object to act on is the generating function of all connected amplitudes whose ordered momenta forms the same polygon shape in momentum space.\(^6\) For simplicity, one may consider instead the generating function of all connected tree level amplitudes \([13]\)

\[ A_c^{(0)}[J] = \sum_{n=4}^{\infty} \frac{g^{n-2}}{n} \int d^{4|4} \Lambda_1 \ldots d^{4|4} \Lambda_n \sum_{s_j = \pm} \text{Tr} \left( J(\Lambda_1^{s_1}) \ldots J(\Lambda_n^{s_n}) \right) A_c^{(0)}(\Lambda_1^{s_1}, \ldots, \Lambda_n^{s_n}), \]  

(6)

where \( \Lambda^\pm = (\lambda, \pm \bar{\lambda}, \eta) \) parametrizes the null momenta and polarizations and the \((0)\) superscript stands for tree level. The sum over \( s_j = \pm \) accounts for positive and negative energy particles. The \( n \)-particle partial amplitude is then given by

\[ A_n^{(0)}(\Lambda_1, \ldots, \Lambda_n) = \frac{1}{N_n^c} \text{Tr} \left( \frac{\delta}{\delta J(\Lambda_n)} \ldots \frac{\delta}{\delta J(\Lambda_1)} \right) A_c^{(0)}[J] \bigg|_{J=0}. \]

When acting on the generating function, the special conformal supercharges take the form

\[ (S_{1\rightarrow 1})_{aA} = \sum_{s= \pm} \int d^{4|4} \Lambda \text{Tr} \left[ \partial_a \partial_A J(\Lambda^s) \bar{J}(\Lambda^s) \right], \]  

(7)

\[ (\bar{S}^{1\rightarrow 1})_\dot{a}^A = - \sum_{s= \pm} \int d^{4|4} \Lambda \eta^A \text{Tr} \left[ \bar{\partial}_\dot{a} J(\Lambda^s) \bar{J}(\Lambda^s) \right], \]

where

\[ \bar{J}(\Lambda) = \frac{\delta}{\delta J(\Lambda)}, \quad s\bar{\partial}_\dot{a} = s \frac{\partial}{\partial \lambda^a} = \frac{\partial}{\partial \bar{\lambda}^a}. \]

\(^5\)We use Latin letters to denote the superconformal generators. Vive la résistance.

\(^6\)That is, the same polygon Wilson loop dual in the sense of \([9]\).
\[ \partial A = \partial / \partial \eta^A \] and the \((1 \to 1)\) subscript indicate that they preserve the number of external particles. In [13] it was shown that a corrected version of the generators do annihilate the generating function. That is

\[ (\tilde{S}_{1\to-1} + g\tilde{S}_{1\to-2}) A_c^{(0)}[J] = 0 , \]  

where \( \tilde{S}_{1\to-2} \) splits a particle into two collinear ones. For the special conformal supercharges, these are given by \(^7\)

\[ (S_{1\to-2})_\tilde{a}^A = +2\pi^2 \sum_{s,s_1,s_2=\pm} s \int d^4\!d^4\eta d^4\eta' d\alpha \lambda_i A_i^{(4)} \text{Tr} \left[ J(\Lambda^s) J(\Lambda_{1}^{s_1}) J(\Lambda_{2}^{s_2}) \right] , \]

\[ (S_{1\to-2})_a^A = -2\pi^2 \sum_{s,s_1,s_2=\pm} s \int d^4\!d^4\eta d^4\eta' d\alpha \delta^{(4)}(\eta') \lambda_i A_i^{(4)} \text{Tr} \left[ J(\Lambda^s) J(\Lambda_{1}^{s_1}) J(\Lambda_{2}^{s_2}) \right] , \]

where

\[ \hat{J}(\Lambda) = \frac{1}{2\pi} \int_0^{2\pi} d\varphi e^{2\varphi i} J(e^{i\varphi} \Lambda) \]

and

\[ \sum_{s,s_1,s_2=\pm} = \sum_{s,s_1,s_2=\pm} \delta_{0,(s,s_1),(s,s_2)} \]

is a sum over the energy signs \( s, s_1 \) and \( s_2 \) such that \( s \in \{ s_1, s_2 \} \). For \( s_1 = s_2 \)

\[ \lambda_1 = \lambda \sin \alpha \quad \eta_1 = \eta \sin \alpha - \eta' \cos \alpha \]

\[ \lambda_2 = \lambda \cos \alpha \quad \eta_2 = \eta \cos \alpha + \eta' \sin \alpha \quad \alpha \in \left[ 0, \frac{\pi}{2} \right] . \]

The other two cases where \( s = s_1 = -s_2 \) and \( s = s_2 = -s_1 \) are related to (11) by replacing \( \sin(\alpha) \to \sinh(\alpha) \) and \( \sin(\alpha) \to \cosh(\alpha) \) correspondently. Moreover, the corrected generators were shown to close the same superconformal algebra (see [13] for details).

At tree level, (8) was claimed to hold at any point in phase space [13]. As we will see in section 5, there are extra points in phase space where the holomorphic anomaly contributes. These are the points where the tree level amplitude factorizes on a multi-particle pole and an internal momentum is collinear to one of the neighboring momenta. Similarly to \( \tilde{S}_{1\to-2} \) correcting \( \tilde{S}_{1\to-1} \), these are accounted for by the inclusion of two new corrections \( \tilde{S}_{2\to-1} \) and \( \tilde{S}_{3\to-0} \). These however (at tree level) act on two or three disconnected tree level partial amplitudes, joining them into a single connected amplitude. Therefore, the object that is superconformal invariant is not the generating function of all connected partial amplitudes (6), but instead the generating function of all partial amplitudes

\[ S_{\text{tree}}[J] = \exp A_c^{(0)}[J] , \]

connected and disconnected. That is the interacting part of the tree level S-matrix (see section 5 for more details). For example, the generator \( \tilde{S}_{2\to-1} \) reads

\[ \tilde{S}_{2\to-1} = 2\pi^2 \sum_{s=\pm} s \int d^4\!d^4\eta d^4\eta' d\alpha \bar{\lambda} \eta' \text{Tr} \left[ J(\Lambda^s) \hat{J}(\Lambda_1^s) \hat{J}(\Lambda_2^s) \right] , \]

where \( \Lambda_1 \) and \( \Lambda_2 \) are given in (11). The corrected tree level symmetry is therefore

\[ (\tilde{S}_{1\to-1} + g\tilde{S}_{1\to-2} + g\tilde{S}_{2\to-1} + g\tilde{S}_{3\to-0}) S_{\text{tree}}[J] = 0 . \]

\(^7\)Here written in a slightly different way than in [13], using for example \( \bar{\lambda} \eta' = \bar{\lambda}_1 \eta_2 - \bar{\lambda}_2 \eta_1 \). Moreover, the overall sign \( s \) in \( \tilde{S} \) seems to have been overlooked in [13].
This structure generalizes to loop level
\[(\bar{S}_{1\rightarrow 1} + g\bar{S}_{1\rightarrow 2} + g\bar{S}_{2\rightarrow 1} + g\bar{S}_{3\rightarrow 0}) S[J] = 0 , \tag{13}\]
where \(S = \exp A_c[J]\) and
\[A_c[J] = \sum_{n=4}^{\infty} \sum_{l=0}^{\infty} g^{2l} A_n^{(l)}[J] \tag{14}\]
is the connected generating function of scattering amplitudes. Here, \((l)\) stands for the number of loops and \(A_n^{(l)}[J]\) is defined as in (6).

Note in particular that the generators do not receive higher loop corrections. The full \(\mathcal{N} = 4\) S-matrix” is obtained from \(S\) by adding the forward amplitudes where some of the particles do not interact. The quotation marks are to remind the reader that, before regularization, \(\mathcal{N} = 4\) SYM is conformal and therefore has no S-matrix. The correction of the formal relation (13) due to the IR regularization will be discussed in the last section.

The aim of this paper is to show that indeed the tree level symmetry (12) generalizes to the loop level (13).

3 Superconformal Invariance of One Loop Unitarity Cuts

Unitarity cuts of an amplitude are physical observable that compute the total cross section in the corresponding channels [27, 28]. These are always less divergent than the full loop amplitude and therefore can provide finite, regularization independent, information. In this section we will compute the finite cuts of \(\bar{S}_{1\rightarrow 1}A\) at one loop and for \(n\) final particles. By doing so, we will obtain an unregularized version of the generators and postpone the issue of regularization to latter sections.

We start by acting with the generator \(\bar{S}_{1\rightarrow 1}\) on a finite cut of the one loop amplitude. To isolate the cut in a specific momentum channel \(t^i_1 = (k_i + \cdots + k_{i+m-1})^2\), we consider the amplitude in the (unphysical) kinematical regime where \(t^i_1 > 0\) and all other momentum invariants are negative. Without loss of generality, we assume that \(i = 1\) and the energy of \(k_1 + \cdots + k_m\) is positive. In that kinematical regime, the discontinuity of the amplitude is computed by
\[\Delta^{[m]}_1 A \equiv A(t^{[m]}_1 + i0^+) - A(t^{[m]}_1 - i0^+) = 2i \text{Im} A(t^{[m]}_1 + i0^+) . \tag{15}\]
For the one loop amplitude, the result is given by (see figure 1)
\[\Delta^{[m]}_1 A_n^{(1)} = (2\pi)^2 \int d^4l_1 d^4l_2 \delta^{(+)}(l^2_1) \delta^{(+)}(l^2_2) \int d^4\eta_{l_1} d^4\eta_{l_2} A_L A_R \tag{16}\]
where
\[A_L = A^{(0)}_{m+2}(l_1, l_2, \ldots, m) , \quad A_R = A^{(0)}_{n-m+2}(-l_2, -l_1, \ldots, n) , \quad \eta_{-l_{1,2}} = -\eta_{l_{1,2}} .\]
The finite cuts are the ones in multi-particle channels \(2 < m < n - 2\) and in that section, we restrict our discussion to that range.
The last term, outside the parentheses, also vanishes since picking the contribution from the holomorphic anomaly, we find indices from \( \bar{S} \) since it is a total derivative.

We conclude that \( \bar{S} \) fails to annihilate the discontinuity only due to the holomorphic anomaly. To see that we first define

\[
\begin{align*}
S_L &= \sum_{i=1}^{m} s_i \eta_i \partial \lambda_i, \\
S_R &= \sum_{i=m+1}^{n} s_i \eta_i \partial \lambda_i, \\
S_{l_1,l_2} &= \sum_{i=1}^{2} \eta_i \partial l_i = -2 \eta_{-l} \partial l_i. 
\end{align*}
\]

Then

\[
S_{1-1} \Delta_1^{[m]} A_n^{(1)} = (2\pi)^2 \int dLIPS(l_1,l_2) \int d^4 \eta_i d^4 \eta_2 \left[ \left( S_L + S_R + S_{l_1,l_2} - S_{l_1,l_2} \right) A_L A_R \right].
\]

If we ignore the anomaly, the term in parentheses does not contribute because \( (S_L + S_{l_1,l_2}) A_L = \bar{S} A_L = 0 \) with similar expressions for \( A_R \). The last term, outside the parentheses, also vanishes since it is a total derivative

\[
\int d^4 t \delta^{(+)1} \bar{A} f(l^b) = \int_0^\infty dt \int_{\lambda=\tilde{\lambda}} \lambda L \partial \lambda f((t\lambda^b)(\tilde{\lambda}^b)) = 0.
\]

We conclude that \( \bar{S} \Delta_1^{[m]} A_n^{(1)} \) is non-zero only due to the holomorphic anomaly. Moreover, for non-collinear external momenta, it is supported on the region of integration where one of the internal momenta is collinear to one of the external momenta adjacent to the cut. For simplicity, we will only consider the case where the \( n \) particle amplitude is MHV. In that case, both tree level sub-amplitudes in (16) are MHV. Using the tree level MHV generating function (2), acting with \( \bar{S} \) and picking the contribution from the holomorphic anomaly, we find [29, 15]

\[
\begin{align*}
\bar{S}_{1-1} \Delta_1^{[m]} A_n^{(1)} &= -i4\pi^3 \left[ \eta_1 P_L^2 - \sum_{i=1}^{m} \eta_i \langle i | P_L [1 \rangle \right] \bar{\lambda}_1 \langle m, m+1 | \theta(t_1^0) \theta(s_1 x_1) \rangle A_n^{(0)} \\
&+ i4\pi^3 \left[ \eta_1 P_L^2 - \sum_{i=1}^{m} \eta_i \langle i | P_L [n \rangle \right] \bar{\lambda}_n \langle m, m+1 | \theta(t_0^n) \theta(s_n x_n) \rangle A_n^{(0)} \\
&+ i4\pi^3 \left[ \eta_m P_L^2 - \sum_{i=1}^{m} \eta_i \langle i | P_L [m \rangle \right] \bar{\lambda}_m \langle n | \theta(t_0^m) \theta(s_m x_m) \rangle A_n^{(0)} \\
&- i4\pi^3 \left[ \eta_{m+1} P_L^2 - \sum_{i=1}^{m} \eta_i \langle i | P_L [m+1 \rangle \right] \bar{\lambda}_{m+1} \langle n | \theta(t_0^m) \theta(s_{m+1} x_{m+1}) \rangle A_n^{(0)} ,
\end{align*}
\]

\(^8\)Note that the internal momenta entering \( A_R \) are \( -l_1 \) and \( -l_2 \). These have negative energy. However, since \( \eta_{-l_1,l_2} = -\eta_{l_1,l_2} \), \( A_R \) is annihilated by the sum \( S_R + S_{l_1,l_2} \) and not by the difference \( S_R - S_{l_1,l_2} \).
Figure 2: The action of the superconformal generator $\bar{S}^{(0)}_{1-1}$ on a one loop unitarity cut. The holomorphic anomalies set an internal momenta to be collinear to an external one, giving rise to a $n + 1$ tree level amplitude with two collinear particles. We deduce that the correction to that generator must be of the form $\bar{S}^{(0)}_{2-1}$.

where $|i|$ stands for $\tilde{\lambda}_i = s_i \tilde{\lambda}_i$ and

$$P_L = \sum_{i=1}^{m} k_i , \quad x_i = \frac{P_L^2}{2 k_i \cdot P_L} , \quad l_i = P_L - x_i k_i . \quad (20)$$

Notice that each line in (19) has a clear origin, represented in figure 2. Namely, the first line comes from the holomorphic anomaly that sets $l_2$ and $\lambda_1$ to be collinear, i.e. it steams from the action of the superconformal generator on $1/(l_2 \lambda_1)$. The other three lines, from top to bottom, come from the action on $1/(l_2 n)$, $1/(m l_1)$ and $1/(l_1 m + 1)$. The relative signs originate from the sign difference between $1/(\lambda_i \lambda_{\alpha})$ and $1/(\lambda_{\alpha} \lambda_i)$, where $l = l_1, l_2$ and $\alpha = 1, m, m + 1, n$.

The two step functions in each term restrict the energy of the two internal on-shell momenta to flow from the left to the right. In the kinematical regime we consider here, these step functions are automatically satisfied. That is because $l_1 + l_2 = P_L$ is a positive energy time-like momenta. We chose to write these step functions explicitly because latter they will be used for understanding the recipe for cutting $\bar{S}^{(0)}_{2-1} A^{(0)}$ in a general kinematical regime.

The calculation above is valid only for $2 < m < n - 2$. The cases $m = 2, n - 2$ deserves a more delicate treatment and will not be considered in this section. Next, we will show that the same expression (19) is obtained from the $(n + 1)$ tree level amplitude, by the action of

$$\bar{S}_{2-1} = 2 \pi^2 \sum_{s=\pm} s \int d^{44} \Delta d^4 \eta' d \alpha \bar{\lambda} \bar{\eta}' \text{Tr} [ J(\Lambda^s) \bar{J}(\Lambda^s_i) J(\Lambda^s_2) ] , \quad (21)$$

where

$$\lambda_1 = \lambda \sin \alpha \quad \eta_1 = \eta \sin \alpha - \eta' \cos \alpha$$
$$\lambda_2 = \lambda \cos \alpha \quad \eta_2 = \eta \cos \alpha + \eta' \sin \alpha \quad (22)$$

Notice that this is indeed the structure indicated by figure 2: we act on a $n + 1$ tree level amplitude rendering two of its legs collinear. Since in the previous section we restrict the one-loop $n$ amplitude

---

9 The holomorphic anomaly that set $l_1$ collinear to $l_2$ do not contribute after preforming the Grassman integration over $\eta_{l_1}$ and $\eta_{l_2}$.
to be MHV, we have to show that
\[ \Delta_1^{[m]} \left[ \bar{S}_{1\rightarrow 1} A_{n+1}^{(1)MHV} + \bar{S}_{2\rightarrow 1} A_{n+1}^{(0)NMHV} \right] = 0, \] (23)
where the number of ±’s stands for the change in the helicity charge (1) with multiplicity of two\(^{10}\). There are three other terms that in principle could have appeared: \( \bar{S}_{1\rightarrow 1} A_{n+1}^{(1)MHV} \), \( \bar{S}_{2\rightarrow 1} A_{n+1}^{(0)MHV} \), and \( \bar{S}_{n+1} A_{n+1}^{(0)N^2MHV} \), where \( \bar{S}_{1\rightarrow 1} \) is a one loop correction of \( \bar{S}_{1\rightarrow 1} \). The first one does not have a cut and the validity of (23) means that \( \bar{S}_{1\rightarrow 1} = \bar{S}_{2\rightarrow 1} = 0 \).

We would like to compare (19) with the cut of \( \bar{S}_{2\rightarrow 1} A_{n+1}^{(0)} \). The collinear \((n+1)\) amplitude is divergent. However, the cut of the generator is finite. That is because the divergent pieces of the collinear amplitude do not have a discontinuity and therefore drop out. The action of \( \bar{S}_{2\rightarrow 1} \) on \( A_{n+1}^{(0)} \) produces a sum of terms in which one of the \( n \)-particles is replaced by two collinear adjacent particles. Only four of these terms have a discontinuity in the \( t_1^{[m]} \) channel. These are the terms in which the particles adjacent to the cut are \(-\{1, m, m+1, n\}\) – see figure 2. Notice that these contributions are indeed finite. For simplicity, we isolate from the action of \( \bar{S}_{2\rightarrow 1} \) on \( A_{n+1}^{(0)} \) the term in which the two collinear momenta are collinear to \( k_1 \). The other terms are related to that by relabeling of the legs. We label the two collinear legs \( 1' \) and \((n+1)'\) to distinguish them from their sum \( 1 = 1' + (n+1)' \) which becomes leg 1 of the \( n \)-particle amplitude. Using (21) we find that the cut in the \( t_1^{[m]} \) channel of that term is

\[ \Delta_1^{[m]} \left[ \bar{S}_{2\rightarrow 1} A_{n+1}^{(0)NMHV} \right] = 2\pi^2 \Delta_1^{[m]} \int d^4 \eta' \eta' \lambda_1 \int_0^1 \frac{dx}{\sqrt{x(1-x)}} A_{n+1}^{(0)NMHV} (1', \ldots, (n+1)'), \]

where \( x = \cos(\alpha) \). It is clear that we can move \( \Delta_1^{[m]} \) freely into the integral and equally write

\[ \left[ \bar{S}_{2\rightarrow 1} \Delta_1^{[m]} A_{n+1}^{(0)NMHV} \right] = 2\pi^2 \int d^4 \eta' \eta' \lambda_1 \int_0^1 \frac{dx}{\sqrt{x(1-x)}} \Delta_1^{[m]} A_{n+1}^{(0)NMHV} (1', \ldots, (n+1)'), \]

Next, we express the tree level amplitude on the right hand side as a CSW sum\(^{11}\) [20], i.e. as a sum over MHV vertices connected by off-shell propagators. As the \((n+1)\)-amplitude at hand is NMHV, any term in the CSW sum consist of two MHV vertices connected by a single propagator. In the kinematical regime we are working, only one term has a discontinuity in the \( t_1^{[m]} \) channel. That is the term (see figure 3)

\[ \Delta_1^{[m]} A^{(0)} ((1-x)1, 2, \ldots, n, x1) = \Delta_1^{[m]} \delta(P_n) \int d^4 \eta \frac{A^{(0)} ((1-x)1, 2, \ldots, m, -l) A^{(0)} (l, m+1, \ldots, n, x1)}{P_L^2 - 2xk_1 \cdot P_L + i0}, \]

where

\[ (\lambda_l)_\alpha = (P_L - xk_1)_{\alpha\dot{a}} \chi^{\dot{a}} \]

and \( \chi \) is an arbitrary fixed null vector. We have removed the subscripts \( n+1, m+1 \) and \( n-m+2 \) since they can be easily read off by counting the number of arguments of the corresponding amplitude. Using (15) and the relation

\[ \frac{i}{y + i0} - \frac{i}{y - i0} = 2\pi \delta(y). \]

---

\(^{10}\)In (1), \( n \) is the number of particles and \( 4k \) is the number of \( \eta' \)'s. Hence removing a leg reduce the helicity by 2 and integrating over \( \eta' \) increase the helicity by 4.

\(^{11}\)The same result can be obtained using BCFW [30] instead. Here, we chose to use CSW because it has a straightforward generalization to loop level which we will use in the next section.
Figure 3: The term in the CSW sum of $A_{n+1}^{(0)}$ that has a cut in $t_1^{[m]} = (k_1 + k_2 + \cdots + k_m)^2$, when integrated over the collinearity portion of leg $1'$ and leg $(n+1)'$.

we simplify $\Delta_1^{[m]} A^{(0)}((1-x)1, 2, \ldots, n, x1)$ in (25) to

$$2\pi i\delta(P_n) \text{sign}(P_L \cdot k_1) \delta(x - x_1) \int d^4\eta d^4\eta' A^{(0)}((1-x)1, 2, \ldots, m, -l_1) \frac{x}{P_L^2} A^{(0)}(l_1, m+1, \ldots, n, x1) ,$$

where $x_1$ and $l_1$ are given in (20)\footnote{Note that the dependence on $\chi$ has dropped out.}. In the kinematical regime we are working in, $P_L^2 > 0$. For $x_1 \in [0, 1]$ it means that sign($P_L \cdot k_1$) = 1. Next, we plug (27) back into (24)

$$\left[ \bar{S}_{2\rightarrow 1} \Delta_1^{[m]} A_{n+1}^{(0)N\text{MHV}} \right]_1$$

$$= i4\pi^3 \bar{\lambda}_1 \int_0^1 dx \delta(x - x_1) \sqrt{\frac{x}{1-x}} \int d^4\eta d^4\eta' A^{(0)}((1-x)1, 2, \ldots, m, -l) A^{(0)}(l, m+1, \ldots, n, x1)$$

$$= i4\pi^3 A^{(0)} \left[ \eta_l P_{L}^2 - \sum_{i=1}^{m} \eta_i |\bar{i}P_{L}|1 \right] \frac{\langle m, m+1 \rangle}{\langle m | P_{L} | 1 \rangle \langle m+1 | P_{L} | 1 \rangle},$$

where in the last step we performed the Grassmanian integration using (22). Note that in the kinematical regime we are working $x_1 = t_1^{[m]}/(t_1^{[m]} - t_2^{[m-1]}) \in [0, 1]$ is always inside the region of integration. The final result in (28) is exactly minus the first line of (19)! A summation over the three other term corresponding to particles $m$, $m + 1$ and $n$ reproduces (19) and confirms (23).

For (23) to hold in a general kinematical regime, we must reproduce the step functions in (19). Physically, these step function restrict the energy flow in the cut lines of figure 1 to flow from the left to the right. The $\theta(l_1^0)$ is reproduced by cutting the tree level propagator between the two MHV vertices

$$\frac{1}{L^2} \rightarrow \delta^{(+)}(L^2).$$

The second step function $\theta(s_1 x_1)$, has to be associated with the procedure of cutting a leg connecting $J_{2\rightarrow 1}$ to the amplitude. It restrict the energy component of the corresponding collinear particle to be positive (see Fig 3). We suggest it to be the general procedure for taking unitarity cuts of $J_{n-m} A$. 

\footnote{Note that the dependence on $\chi$ has dropped out.}
4 Formal Superconformal Invariance of One Loop MHV Amplitudes

In the previous section we demonstrated the superconformal invariance of unitarity cuts. In this section we will show that a formal invariance continues to hold for the full one loop MHV amplitude. The invariance will only be formal because some of the integrals we will consider are divergent. That is however not the first time where non-trivial information is obtained from formal manipulations of divergent integrals. For example, in [31] Bern, Dixon, Dunbar and Kosower computed the one loop MHV amplitudes of $\mathcal{N} = 4$ SYM by formal manipulations of its unitarity cuts. What allowed them to do so was the independent knowledge that these amplitudes are given by a sum of box integrals. In our case the logic is different. That is, we will use these formal manipulations to define the superconformal generators. Then, in section 6, we will show that up to a conformal anomaly, the structure survives regularization.

We start by repeating the computation of $\bar{S}_{2\to1}A_{n+1}^{(0)}$ above but without taking its unitarity cut. That is, we formally remove the cut from (24)

$$\left[\bar{S}_{2\to1}A_{n+1}^{(0)\text{NMHV}}\right]_1 = 2\pi^2 \int d^4\eta' \int_0^1 dx \frac{dx}{x(1-x)} A_{n+1}^{(0)\text{NMHV}}(1', \ldots, (n+1)')$$

and represent the tree amplitude as a CSW sum [20]

$$A_{n+1}^{(0)\text{NMHV}}(1', \ldots, n+1) = -i \sum_{i=1}^{n+1} \sum_{m=2}^{n-1} \int d^4\eta_l \int d^4\eta_r \bar{A}_L^{(0)\text{MHV}} A_R^{(0)\text{MHV}}$$

where

$$\bar{A}_L^{(0)\text{MHV}} = \delta^4(P_L + L) A_{m+1}^{(0)\text{MHV}} (l, i, \ldots, i+m-1),$$

$$\bar{A}_R^{(0)\text{MHV}} = \delta^4(P_R - L) A_{n-m+1}^{(0)\text{MHV}} (-l, i+m, \ldots, i-1),$$

and

$$P_L = \sum_{r=i}^{i+m-1} k_r, \quad P_R = \sum_{r=i+m}^{i-1} k_r, \quad l = L - y\chi, \quad y = \frac{P_L^2}{2P_L \cdot \chi},$$

where $\chi$ is an arbitrary null vector. The only difference between the $\bar{A}_{n}^{(0)\text{MHV}}$ and tree level MHV amplitudes $A_{n}^{(0)\text{MHV}}$ is in the momentum conservation delta function where the off-shell momentum $L$ enters and not the on-shell momenta $l$. The superconformal generator in (29) sets two of the momenta in (30) to be collinear; these two momenta can belong to different sub-amplitudes (one in $A_L$, the other in $A_R$) or they can be on the same side (both in $A_L$ or both in $A_R$). Terms where the two collinear momenta are on the same side vanish when plugged into (29). That is because these terms are proportional to $\langle 1'(n+1)' \rangle^{3}$ whereas the Grassman integral over $\eta'$ produces a factor of $\langle 1'(n+1) \rangle^{2}$ (resulting in a total factor of $\langle 1'(n+1)' \rangle^{3}$).

13Not only the off-shell amplitudes $\bar{A}_{n}^{(0)\text{MHV}}$ are still annihilated by $\bar{S}_{1\to1}$ for generic external momenta but also the correction $\bar{S}_{1\to2}$ required to account for collinear external momenta comes from the same holomorphic anomaly and is therefore trivially generalized to act on these amplitudes. The generators $\bar{S}_{1\to1}$ and $\bar{S}_{1\to2}$ generalized to act on these amplitudes will be given latter in (51) and (52).
Of course (30) can be simplified using
\[
\int \frac{d^4L}{L^2} \delta^4(P_L + L) \delta^4(P_R - L) = \frac{\delta^4(P_L + P_R)}{P_L^2}.
\]
We will not do so here but instead express it as \[21\]
\[
\int \frac{d^4L}{L^2} \delta^4(P_L + L) = \int \frac{dy}{y} \int d^4 l \delta(l^2) \delta^4(P_L + y \chi + l) \text{sign}(\chi \cdot l) .
\] (33)
Preforming the Grassman integrations over \(\eta_l\) and \(\eta'_l\), we get
\[
\left[ \tilde{S}_{2-1} A^{(0)NMHV}_{n+1} \right]_1 = i 2 \pi^2 \tilde{\lambda}_1 A_n^{(0)} \sum_{m=2}^{n-1} \int_0^1 dx \int \frac{dy}{y} \int d^4 l \delta(l^2) \delta^4(P_{L,y} - x k_1 - l) \text{sign}(\chi \cdot l)
\]
\[
\times \frac{1}{P_{L,y}^2} \left[ \eta_l P_{L,y}^2 - \sum_{j=1}^m \eta_j \langle j | P_{L,y} | 1 \rangle \right] \langle l \rangle^2 \langle m, m+1 \rangle \langle m | P_{L,y} | 1 \rangle \langle m+1 | P_{L,y} | 1 \rangle .
\]
where\[14\]
\[P_{L,y} = k_1 + \cdots + k_m - y \chi .\] (34)
We can now integrate over \(y\) and \(l\) to obtain
\[
\left[ \tilde{S}_{2-1} A^{(0)NMHV}_{n+1} \right]_1 = i 2 \pi^2 \tilde{\lambda}_1 A_n^{(0)} \sum_{m=2}^{n-1} \int_0^1 dx \frac{P_{L,y}^2}{P_{L,x}^2} \left[ x P_{L,y}^2 - \sum_{j=1}^m \eta_j \langle j | P_{L,y} | 1 \rangle \right] \frac{\langle m, m+1 \rangle}{\langle m | P_{L,y} | 1 \rangle \langle m+1 | P_{L,y} | 1 \rangle} ,
\]
where\[15\]
\[
y = \frac{P_{L,x}^2}{2 P_{L,x} \cdot \chi} , \quad P_{L,x} = k_1 + \cdots + k_m - x k_1 .
\]
Before we move on and consider the action of the superconformal generators on the one loop amplitude, a few comments are in order:

- Taking the cut of (35) in the \(t_1^{[m]}\) channel localizes the \(y\)-integral at \(y = 0\), yielding (28).
- Any term in the sum depends on the arbitrary chosen null vector \(\chi\). The sum is however \(\chi\) independent.
- For compactness of the expressions above, we have dropped the explicit \(i \epsilon\) prescription of the Feynman propagator. It is trivial to add it back as will be done below.
- For \(m = 1, 2, n-2, n-1\) the integrals in (35) are divergent. In section 6 we will deal with their regularization.

\[14\] When acting with the superconformal generator, the momenta \(k_1 \in P_L\) becomes \(k_1' = (1-x)k_1\) hence justifying the extra term \(-x k_1\) inside the delta function.

\[15\] Note that \(\int \frac{dx}{x} \frac{P_{L,y}^2}{P_{L,x}^2} = \int \frac{dy}{y} .\]
Next, we would like to compare (35) with the action of $\bar{S}_{1-1}$ on the $n$-particle MHV amplitude $A_{n}^{(1)\text{MHV}}$. In [21], a generalization of the CSW formula to one-loop MHV amplitudes was given as

$$A_{n}^{(1)\text{MHV}} = -2\pi i \sum_{i=1}^{n} \sum_{m=1}^{n-1} \int \frac{dy}{y+i0} \int d^4 l_1 d^4 l_2 \delta^{(+)}(l_1^2) \delta^{(+)}(l_2^2) \int d^4 \eta_1 d^4 \eta_2 \bar{A}_{L}^{(0)\text{MHV}} \bar{A}_{R}^{(0)\text{MHV}},$$  

(36)

where

$$\bar{A}_{L}^{(0)\text{MHV}} = \delta^{4}(P_{L} - l_1 - l_2 - y \chi) A_{m+1}^{(0)\text{MHV}} (-l_1, -l_2, i, \ldots, i + m - 1),$$

$$\bar{A}_{R}^{(0)\text{MHV}} = \delta^{4}(P_{R} + l_1 + l_2 + y \chi) A_{n-m+1}^{(0)\text{MHV}} (l_2, l_1, i + m, \ldots, i - 1),$$

the left and right momenta $P_{L}, P_{R}$ are given in (32) and we have chosen $\chi$ to have positive energy ($\chi^0 > 0$).\footnote{The step functions $\theta(l_1^0) \theta(l_2^0)$ imply that $P_{L} - y \chi$ is the sum of two positive energy null momenta and must therefore be a (positive energy) time-like vector. Thus, the integrand in each of the summands in (36) is nonzero for $y \geq -\frac{P_{L}^2}{2\chi P_{L}}$ (for $m = 1$ this yields $y \geq 0$).}

For any fixed value of $y$, the dLIPS integral in (36) computes the discontinuity of a one loop amplitude in the $P_{L,y}$ channel (where the tree level amplitude has been factored out). It depends on $y \chi$ only through the momentum conservation delta functions in (37). We can therefore apply the result of section 3 directly to the loop amplitude. As before, $\bar{S}_{1-1}$ fails to annihilate the one loop amplitude only due to the holomorphic anomaly and we isolate the term in which an internal on-shell momenta is collinear to $k_1$

$$[\bar{S}_{1-1} A_{n}^{(1)\text{MHV}}]_1 = -i2\pi i A_{n}^{(0)\text{MHV}} \sum_{m=2}^{n} \int_{0}^{1} \frac{dx}{x} \frac{P_{L,y}^2}{P_{L,x}} \left[ \eta_1 P_{L,y}^2 - \sum_{j=1}^{m} \eta_j \langle j | P_{L,y} | 1 \rangle \right] \frac{\langle m, m+1 \rangle}{\langle m | P_{L,y} | 1 \rangle \langle m+1 | P_{L,y} | 1 \rangle},$$

(38)

where

$$x = \frac{P_{L,y}^2}{2P_{L,y} \cdot k_1}.$$

Comparing with (35) we see that, at the level of formal integrals, we obtain a match between the two expression, i.e.,

$$\bar{S}_{1-1} A_{n}^{(1)\text{NMHV}} + \bar{S}_{2-1} A_{n+1}^{(0)\text{NMHV}} = 0.$$

(39)

In obtaining (38) there were two point that deserve explanation.

\begin{itemize}
  \item It is quite nontrivial that we obtain precisely the same region of integration $0 < x < 1$ in (38) and in (35). Each $m$ summand in (38) originates from four terms in the action of $\bar{S}_{1-1}$ on (36). These are the terms in which $(i, m)$ in (36) are equal to \{$(1, m)$, $(m + 1, n - m)$, $(2, m - 1)$, $(m + 1, n - m + 1)$\}, where the first two are drawn in figure 4.a and the last two in figure 4.b. Each of these four terms is the same as (38) with the integrand multiplied by the following step functions (see (19))

$$\begin{align*}
  (1, m) : & \quad +s_1 \theta((P_{L,y}^0 - x k_1^0)) \theta(x k_1^0) \\
  (m + 1, n - m) : & \quad -s_1 \theta(-(P_{L,y}^0 - x k_1^0)) \theta(-x k_1^0) \\
  (2, m - 1) : & \quad -s_1 \theta((P_{L,y}^0 - x k_1^0)) \theta(-(1 - x) k_1^0) \\
  (m + 1, n - m + 1) : & \quad +s_1 \theta(-(P_{L,y}^0 - x k_1^0)) \theta((1 - x) k_1^0).
\end{align*}$$

(40)
\end{itemize}
Figure 4: a and b are terms that appear in the action of $\hat{S}^{(0)}_{1\rightarrow 1}$ on the one loop MHV $n$-particle amplitude $A^{(1)}_n$, see figure 2. They correspond to two different terms in the CSW sum of the loop amplitude where an internal on-shell momenta become collinear to $k_1$. Their sum is equal to a term in $\hat{S}^{(0)}_{2\rightarrow 1}A^{(0)}_{n+1}$ where the two collinear particles are collinear to $k_1$. That term is drawn on the left.

When summing these four terms the dependence on $P_L$ and $s_1$ drops out leaving just

$$\theta(x)\theta(1-x),$$

as in (38). The cancelation of the $P_L$ dependence in the region of the $x$ integration is essential for the locality of the correction $\hat{S}^{(0)}_{2\rightarrow 1}$. Notice that for (39) to hold, it was crucial that in the definition of $\hat{S}^{(0)}_{2\rightarrow 1}$ the portion of collinearity $x$ was integrated only between 0 and 1. Physically this means that the two collinear particles have the same energy sign.

- Note that the sum in (38) starts at $m = 2$. On the other hand, the CSW one loop sum (30) contains a term where $(m, i) = (1, 1)$. That is the term where one of the MHV vertices is a three vertex connecting particle 1 to the two internal propagators. It already contributes to (38) from the regions of integration where $l_1$ become collinear to $k_2$ or $l_2$ becomes collinear to $k_n$. One may expect that it will also contribute to (38) from the region of integration where an internal momentum becomes collinear to $k_1$. In that term, the momentum conservation delta function of the MHV three vertex is $\delta^4(k_1 - y \chi - l_2 - l_1)$. Suppose $l_1 = tk_1$. The only way to have momentum conservation is if $y = 0$ or $t = 1$.\(^{17}\) The point $t = 1$ is however a point of measure zero in the dLIPS integration. The corresponding holomorphic anomaly is therefore supported at the point where $y = 0$. That is the point where the original $y$-integrand is divergent. A formal manipulation of that contribution is therefore invalid. In other words, to make any sense out of that contribution, we must first introduce a regulator. After regularization, that contribution vanish. As the details are technical and involve a regularization not yet introduced, we present them in Appendix A.

\(^{17}\)That is, generically the holomorphic anomaly is supported outside the region of integration.
5 Generalizations to All Loops and Helicities

In [21, 22] a generalization of the CSW formula to one-loop MHV amplitudes was given as\(^{18}\)

\[
A^{(1)\text{MHV}}_n = -\sum_{i=1}^n \sum_{m=1}^{n-1} \int \frac{d^4L_1}{L_1^2 + i0} \int \frac{d^4L_2}{L_2^2 + i0} \int d^4\eta_1 d^4\eta_2 \tilde{A}_L \tilde{A}_R ,
\]

(42)

where

\[
\begin{align*}
\tilde{A}_L &= \delta^4(P_L + L_1 + L_2)A^{(0)\text{MHV}}_{m+1}(l_2, l_1, i, \ldots, i + m - 1) \\
\tilde{A}_R &= \delta^4(P_R - L_1 - L_2)A^{(0)\text{MHV}}_{n-m+1}(-l_1, -l_2, i + m, \ldots, i - 1)
\end{align*}
\]

(43)

and

\[
L_i = l_i + y_i \chi .
\]

(44)

Here \(\chi\) is an arbitrary chosen null vector. For every fixed values of \(i\) and for every \(m\) in the sum we can express the \(L_1\) integral as

\[
\int \frac{d^4L_1}{L_1^2 + i0} \delta^4(P_{L_m} + L_1) = \int d^4l_1 \delta(l_1^2) \text{sign}(l_1^0) \int \frac{dy}{y + i0 \text{ sign}(l_1^0)} \delta^4(P_{L_m} + l_1 + y\chi) ,
\]

where

\[
P_{L,m} = L_2 + \sum_{j=i}^{i+m-1} k_j
\]

and the energy sign of \(\chi\) was chosen to be positive. Now, for every fixed value of \(i, y\) and \(l_1\), the sum over \(m\) reproduce the CSW formula for an \((n + 2)\) tree level (off-shell continued) NMHV amplitude \(\tilde{A}_{n+2}^{(0)\text{NMHV}}\) with two adjacent legs been \(l_1\) and \(-l_1\) with momentum insertions \(l_1 + y\chi\) and \(-l_1 - y\chi\) correspondently\(^{19}\) (when expressing \(\tilde{A}_{n+2}^{(0)\text{NMHV}}\) as a CSW sum, the null momenta used to go off-shell must be \(\chi\) and cannot be chosen independently). We have then

\[
A^{(1)\text{MHV}}_n = -i \sum_{i=1}^n \int d^4l \delta(l^2) \text{sign}(l^0) \int \frac{dy}{y + i0 \text{ sign}(l^0)} \int d^4\eta \tilde{A}_{n+2}^{(0)\text{NMHV}}[(l, y\chi), (-l, -y\chi), i, \ldots, i + n - 1]
\]

(45)

where \(\tilde{A}^{(0)}\) is the off-shell continuation of tree-level amplitudes by means of momentum conservation at MHV vertices. That is, the external momenta entering \(\tilde{A}\) can be off-shell and are treated in the same way as internal off-shell momenta via the CSW prescription [20].

We can replace the \(\text{sign}(l_0)\) in this expression by explicitly summing over positive and negative energy momenta \(l\) thus obtaining

\[
A^{(1)\text{MHV}}_n = -i \sum_{i=1}^n \sum_{s = \pm} \int \frac{dy}{y + i0} \int \frac{d^4L}{2\pi} \tilde{A}_{n+2}^{(0)\text{NMHV}}[(sl, sy\chi), (-sl, -sy\chi), i, \ldots, i + n - 1] ,
\]

(45)

---

\(^{18}\)The relation between (42) and (36) will be reviewed in detail in the next section.

\(^{19}\)To be more precise, the CSW tree level sum also includes terms where the legs \(l_1\) and \(-l_1\) are attached to the same MHV vertex. These terms are proportional to the tree level splitting function that diverge as \(1/(l_1^2 - l_1^2)\). However, the Grassmanian integration over \(\eta_l\) produces a factor of \((||l_1^2 - l_1^2||)^4\), killing these terms [22]. Note that even if we multiply first by \(\eta_l^4\), these terms will not contribute.
where \( d^4 \Lambda = d^4 \delta^{(+)}(P^2) d^4 \eta d \phi \).

We will now use the above observation to conjecture a generalization of CSW [20] to any loop order and any helicity configuration (not necessarily MHV). For that aim, we first introduce a couple of definitions

- We define the generating function of all generalized MHV vertices
  \[
  \bar{A}_c^{(0)}_{\text{MHV}}[J] = \sum_{n=3}^{\infty} \frac{1}{n^2} \int \prod_{i=1}^{n} d^4 \Lambda_i dy_i \, \text{Tr}[J(\bar{\Lambda}_{1,y_1}) \cdots J(\bar{\Lambda}_{n,y_n})] \bar{A}_c^{(0)}_{\text{MHV}}(\Lambda_{1,y_1}, \ldots, \Lambda_{n,y_n}) ,
  \]
  where \( \bar{\Lambda}_y^\pm = (\Lambda^\pm, y) \) and
  \[
  \bar{A}_c^{(0)}_{\text{MHV}}(\Lambda_{1,y_1}, \ldots, \Lambda_{n,y_n}) = \delta^4 \left( \sum_{i=1}^{n} (k_i + y_i \chi) \right) A_c^{(0)}_{\text{MHV}}(\Lambda_1, \ldots, \Lambda_n) .
  \]

- Next, we define the “propagator inserting operator”
  \[
  L = i \int \frac{dy}{y + i0} \int \frac{d^4 \Lambda}{2\pi} \text{Tr}[\tilde{J}(\bar{\Lambda}_y) \tilde{J}(-\bar{\Lambda}_y)] ,
  \]
  where \( \tilde{J}(\bar{\Lambda}_y) = \frac{\delta}{\delta J(\bar{\Lambda}_y)} \) and \( (-\bar{\Lambda}_y) = (\lambda, -\bar{\lambda}, -\eta, -y) \).

- Finally, we express the full \( \mathcal{N} = 4 \) S-matrix \( S_{\text{matrix}} \) (generating all connected, disconnected, planar and non-planar amplitudes) as
  \[
  S_{\text{matrix}}[J] = e^{F[J]} S[J] ,
  \]
  where \( F[J] = \int d^4 \Lambda \text{Tr}[J(\Lambda^+) \tilde{J}(\Lambda^-)] \) is introduced to take into account from sub-processes where some of the particles fly by unscattered and \( S \) is the interacting part of the S-matrix. It is equal to the exponent of all connected amplitudes with three or more external particles.\(^{20}\)

Using these definitions, the conjectured CSW generalization reads

\[
S[J] = e^L e^{\bar{A}_c^{(0)}_{\text{MHV}}[J]} .
\]

Note that at tree level and for one loop MHV amplitudes this is not a conjecture, see respectively [30, 32] and [21].\(^{21}\) We will now study the symmetry transformations of this object; the transformation properties of the full S-matrix \( S_{\text{matrix}} \) will then be read off from these. We start by writing a

\(^{20}\)Note that \( S \) is not the transfer matrix (the latter only excludes the process where all particles fly by unscattered).

\(^{21}\)The CSW construction was argued to hold for any helicity configuration in [22]. Furthermore, the existence of an MHV Lagrangian which is obtained from the usual one by a field redefinition after light-cone gauge fixing [35] provides additional strong evidence towards the exactness of this expansion, see [33] where the (non-local) field redefinitions were argued to be mild enough not to raise any issues at both tree level and one loop.
Figure 5: Result of the action of $\bar{S}_{1\rightarrow 1}$ on $S^{(1)}$. The operator $\bar{S}_{1\rightarrow 1}$ goes through $\mathcal{L}$ thus acting on the MHV tree level generating function $S^{(0)}$. From [13] this gives rise to the action of $\bar{S}_{1\rightarrow 2}$ on $S^{(0)}$. The two legs created by $\bar{S}_{1\rightarrow 2}$ can (a) be unrelated to the legs on which $\mathcal{L}$ acts, thus yielding terms which vanish for generic external momenta, (b) be acted upon by $\mathcal{L}$, giving a vanishing contribution due to the Grassmanian integration or (c,d) one of them can become an external leg while the other is acted upon by $\mathcal{L}$. The latter two contributions are identified with $\bar{S}_{2\rightarrow 1}$, (see figure 6).

recursive relation for the number of propagators between CSW MHV vertices. To do so, we first introduce a parameter $x$ counting the number of such propagators

$$S[x, J] = e^{x\mathcal{L}} e^{\bar{\mathcal{A}}^{(0)\text{MHV}}[J]} = \sum_{m=0}^{\infty} x^m S^{(m)}[J].$$

To obtain the S-matrix, we set $x = 1$

$$S[J] = S[1, J].$$

We can now write a recursive relation these coefficients\(^{22}\)

$$S^{(m)}[J] = \frac{\mathcal{L}}{m} S^{(m-1)}[J].$$

(49)

Let us now explain how we can recover and generalize our previous results assuming (48). First, we note that for $\bar{S}$, the results of [13] applies as well for generalized tree level MHV amplitudes (these are the CSW vertices)\(^{23}\)

$$(\bar{S}_{1\rightarrow 1} + g\bar{S}_{1\rightarrow 2}) S^{(0)}[J] = 0,$$

(50)

where for generalized off-shell legs

$$\bar{S}_{1\rightarrow 1} = -\sum_{s=\pm} s \int d^{4/4} \Lambda dy \eta \text{Tr} \left[ \tilde{\partial} J(\tilde{\Lambda}_y^s) \tilde{J}(\tilde{\Lambda}_y^s) \right],$$

(51)

$$\bar{S}_{1\rightarrow 2} = 2\pi^2 \sum_{s_1, s_2, s_0 = \pm} s_0 \int dy_1 dy_2 \int d^{4/4} \Lambda d^4 \eta d^4 \bar{\Lambda} d^4 \eta' \text{Tr} \left[ J(\tilde{\Lambda}_{y_1}^{s_1} + y_2) \tilde{J}(\tilde{\Lambda}_{y_1}^{s_1}) J(\tilde{\Lambda}_{y_2}^{s_2}) \right].$$

(52)

\(^{22}\)Here and everywhere the tilde stands for generalized off-shell amplitudes in the CSW sense.

\(^{23}\)Note that MHV amplitudes don’t have multi-particle poles.
Figure 6: The combined action of the propagator inserting operator \( \mathcal{L} \) and the leg splitting operator \( S_{1\rightarrow 2} \) gives rise to the leg joining operator \( \bar{S}_{2\rightarrow 1} \).

Now we recursively act with the bare generator \( \bar{S}_{1\rightarrow 1} \) on \( S^{(1)}[J] \) using (49)
\[
\bar{S}_{1\rightarrow 1} S^{(1)}[J] = \bar{S}_{1\rightarrow 1} \mathcal{L} S^{(0)}[J] = \mathcal{L} \bar{S}_{1\rightarrow 1} S^{(0)}[J] = -g \mathcal{L} \bar{S}_{1\rightarrow 2} S^{(0)}[J]
\]
\[
= -g \bar{S}_{1\rightarrow 2} S^{(1)}[J] - g \mathcal{L} \bar{S}_{1\rightarrow 2} S^{(0)}[J],
\]
where when commuting \( \mathcal{L} \) through \( \bar{S}_{1\rightarrow 1} \), we used the fact that \( l \) is not an external leg and that
\[
\bar{S}_{l} = \eta \frac{\partial}{\partial \lambda_{l}} = \eta_{-l} \frac{\partial}{\partial \lambda_{-l}} = \bar{S}_{-l}
\]
is a total derivative. Now, (see figure 6)
\[
[\mathcal{L}, \bar{S}_{1\rightarrow 2}] = i \pi \int \frac{dy}{y + i0} \sum' s \int d^4 \Lambda d^4 \eta' d\alpha d\lambda \text{Tr} \left[ J(\bar{\Lambda}_{s1y}) J(-\bar{\Lambda}_{s1y}) J(\Lambda_{s2}) \right] + i \pi \int \frac{dy}{y + i0} \sum' s \int d^4 \Lambda d^4 \eta' d\alpha d\lambda \text{Tr} \left[ \bar{J}(\bar{\Lambda}_{s2y}) \bar{J}(\Lambda_{s2}) J(\Lambda_{s1}) \right],
\]
The two terms in (54) comes from contracting the right (1) and the left (2) legs of \( \bar{S}_{1\rightarrow 2} \) with a neighboring leg using \( \mathcal{L} \). These are drawn in figures 6.a and 6.b respectively. By the following change of variables in the last line
\[
(s, s_1, s_2, y) \rightarrow (-s_1, s_2, -s, s s_1 y),
\]
the sum of the two terms can be rewritten as
\[
[\mathcal{L}, \bar{S}_{1\rightarrow 2}] = \pi \sum' s \int dy \left[ \frac{i}{y + i0} - \frac{i}{y + i s s_1 y} \right] \int d^4 \Lambda d^4 \eta' d\alpha d\lambda \text{Tr} \left[ \bar{J}(\bar{\Lambda}_{s1y}) \bar{J}(\Lambda_{s1}) J(\Lambda_{s2}) \right].
\]
For \( s = s_1 \) the two terms cancel. That is the same cancelation obtained in (41). For \( s = -s_1 \) (and therefore \( s = s_2 \)), the two terms gives a delta function (26). We conclude that
\[
(\bar{S}_{1\rightarrow 1} + g \bar{S}_{1\rightarrow 2}) S^{(1)}[J] + g \bar{S}_{2\rightarrow 1} S^{(0)}[J] = 0,
\]
where
\[
\bar{S}_{2\rightarrow 1} = 2 \pi^2 \sum_{s = \pm} s \int d^4 \Lambda d^4 \eta' d\alpha d\lambda \text{Tr} \left[ J(\Lambda_{s}) J(\Lambda_{s}) J(\Lambda_{s}) \right],
\]
\[
\bar{S}_{1\rightarrow 1} S^{(1)}[J] = \bar{S}_{1\rightarrow 1} \mathcal{L} S^{(0)}[J] = \mathcal{L} \bar{S}_{1\rightarrow 1} S^{(0)}[J] = -g \mathcal{L} \bar{S}_{1\rightarrow 2} S^{(0)}[J],
\]
\[
= -g \bar{S}_{1\rightarrow 2} S^{(1)}[J] - g \mathcal{L} \bar{S}_{1\rightarrow 2} S^{(0)}[J],
\]
Figure 7: The generator $\tilde{S}_{3-0}$ obtained by composing twice the propagator inserting operator $L$ with the splitting generator $\tilde{S}_{1-2}$.

is independent of $\chi$ and

$$
\begin{align*}
\lambda_1 &= \lambda \sin \alpha & \eta_1 &= \eta \sin \alpha - \eta' \cos \alpha \\
\lambda_2 &= \lambda \cos \alpha & \eta_2 &= \eta \cos \alpha + \eta' \sin \alpha
\end{align*}
$$

This is precisely the form of the generator (21) derived in the previous sections from the direct action on one loop MHV amplitudes. Next, we use (49) and (55) to act with $\tilde{S}_{1-1}$ on $S^{(2)}[J]$

$$
\tilde{S}_{1-1}S^{(2)}[J] = -gL \left( \tilde{S}_{1-2}\tilde{S}^{(1)}[J] + \tilde{S}_{2-1}\tilde{S}^{(0)}[J] \right)
$$

$$
= -g\tilde{S}_{1-2}\tilde{S}^{(2)}[J] - g\tilde{S}_{2-1}\tilde{S}^{(1)}[J] - g\tilde{S}_{3-0}\tilde{S}^{(0)}[J].
$$

The new term appearing in (58) is (see figure 7)

$$
\tilde{S}_{3-0} = \frac{1}{2} [L, \tilde{S}_{2-1}] = \frac{1}{2} [L, [L, \tilde{S}_{1-2}]]
$$

$$
= \frac{1}{2} \sum_{s,s_1,s_2 = \pm} s s_1 s_2 \int dy_1 dy_2 G_{12} \int d^4\Lambda d^4\Lambda' d\alpha d\lambda d\lambda' Tr \left[ \tilde{J}(\Lambda_{y_1+y_2})\tilde{J}(\Lambda_{2,y_2})\tilde{J}(\Lambda_{1,y_1}) \right],
$$

where

$$
G_{12} = -\frac{1}{3} \left[ \frac{1}{y_1 + is_1y_2} - \frac{1}{y_1 + is_1y_2} - \frac{1}{y_1 + is_0y_2 + is_2} - \frac{1}{y_1 + y_2 + is_0y_2 + is_2} \right].
$$

represents the propagators in the three possible combinations represented in figure 7. Similarly to (26) we now have $G_{12} = \pi^2 \delta(y_1)\delta(y_2)(1 + s_1 s_2)(1 - s s_1)/3$. Plugging it back into (59), we conclude that

$$
\tilde{S}_{3-0} = \frac{2\pi^2}{3} \sum_{s = \pm} s \int d^4\Lambda d^4\Lambda' d\alpha d\lambda d\lambda' Tr \left[ \tilde{J}(\Lambda_s)\tilde{J}(\Lambda_s)\tilde{J}(\Lambda_s) \right].
$$

Since $\tilde{S}_{3-0}$ does not have external legs (to be contracted with $L$), it commutes with the propagator inserting operator

$$
[L, \tilde{S}_{3-0}] = 0.
$$

Thus, if we now go to higher orders in our recursive argument, no new corrections to the special superconformal generator $\tilde{S}$ are produced. Collecting the terms in the $x$ expansion of $\tilde{S}_{1-1}S[J]$ we conclude that

$$
(\tilde{S}_{1-1} + g\tilde{S}_{1-2} + gx\tilde{S}_{2-1} + gx^2\tilde{S}_{3-0})S[x,J] = 0.
$$
By setting $x = 1$, we obtain

$$\left( \bar{S}_{1\rightarrow 1} + g\bar{S}_{1\rightarrow 2} + g\bar{S}_{2\rightarrow 1} + g\bar{S}_{3\rightarrow 0} \right) S[J] = 0.$$  \hspace{1cm} (61)

A few comments are in order:

- Note that even though in our derivation we used a generalization of CSW (48) that technically involved a choice of a reference null vector $\chi$, it dropped out of all our final results.

- Naively, the action of $\mathcal{L}\bar{S}_{1\rightarrow 1}$ on a connected amplitude also produces an holomorphic anomaly proportional to $\delta^2(\langle l, -l \rangle)$. Due to the Grassmanian integration, there is no such contribution (see Fig 6.b).

- The operator $\bar{S}_{2\rightarrow 1}$ contributes only when the two collinear particles have the same energy sign. The reason for that is a cancelation between the two terms in $[\mathcal{L}, \bar{S}_{1\rightarrow 2}]$ (see figure 7). In that sense, $\bar{S}_{2\rightarrow 1}$ is different from the tree level corrections $\bar{S}_{3\rightarrow 0}$, where the two collinear particles can have opposite energy sign [13]. Generalizing these two generators with $\bar{S}_{3\rightarrow 0}$, we see that all corrections to the generators are made from the same three vertex connected to the amplitude by cut propagators.

The corrections to the conjugate special superconformal generator $S$ are obtained in an identical way using anti-MHV CSW rules

$$S_{2\rightarrow 1} = -\frac{2\pi^2}{3} \sum_{s=\pm} \int d^4 \eta d^4 \eta' d\alpha \delta(\eta') \partial / \partial \eta' Tr \left[ J(\Lambda^s) J(\Lambda^s_1) J(\Lambda^s_2) \right]$$

$$S_{3\rightarrow 0} = -\frac{2\pi^2}{3} \sum_{s=\pm} \int d^4 \eta d^4 \eta' d\alpha \delta(\eta') \partial / \partial \eta' Tr \left[ J(-\Lambda^s) J(\Lambda^s_2) J(\Lambda^s_1) \right]$$

where $\Lambda_1$ and $\Lambda_2$ are given in (57). The special conformal generator can be obtained by commuting the superconformal generators as in (4). This is one of the advantages of the approach of this section. Namely, since we obtain the corrected generators at one loop by acting on the tree level generators with the propagator inserting operator $\mathcal{L}$, we automatically get the good commutation relations for free: it suffices to conjugate (a straightforward off-shell generalization of) the commutation relations of [13] by the propagator inserting operator $\mathcal{L}$.

We can now read the transformation of the full $S$-matrix $S_{\text{matrix}}$ (46) by multiplying (61) by $e^F$ (47) and commuting this through the generators. In this way we obtain

$$\left( \bar{S}_{1\rightarrow 1} + g\bar{S}_{1\rightarrow 2} + g\bar{S}_{0\rightarrow 3} \right) S_{\text{matrix}}[J] = 0.$$  \hspace{1cm} (63)

where

$$\bar{S}_{0\rightarrow 3} = -\frac{2\pi^2}{3} \sum_{s=\pm} s \int d^4 \Lambda d^4 \eta d\alpha \partial / \partial \eta \partial / \partial \eta' Tr \left[ J(\Lambda^s) J(\Lambda^s_2) J(\Lambda^s_1) \right].$$

The correction $\bar{S}_{0\rightarrow 3}$ do not contain functional derivatives $\bar{J}$ and with this respect it is distinct from $\bar{S}_{1\rightarrow 1}$ and $\bar{S}_{3\rightarrow 0}$. Note also that $\bar{S}_{2\rightarrow 1}$ and $\bar{S}_{1\rightarrow 2}$ are automatically reproduced from commuting $\bar{S}_{3\rightarrow 0}$ through $e^F$ and need not be included in (63).

22
Figure 8: The action of the bare superconformal generator $\bar{S}_{1\rightarrow 1}$ on an amplitude at the point where it factorizes on a multi particle pole result in a new anomaly. The anomaly is identified with correction $\bar{S}_{2\rightarrow 1}$ to $\bar{S}_{1\rightarrow 1}$, acting on two disconnected amplitudes. In the T-dual polygon Wilson loop picture of $[9]$, the collinear multi particle factorization points correspond to configurations where a cusp collides with an edge. The superconformal generator mixes that configuration with two disjoint polygons touching at a point.

5.1 Superconformal Invariance of the Tree Level S-matrix

Our derivation of the main result (61) is valid at any loop order. In this section we will consider the implication of this relation for tree level amplitudes.

The first term is the only one which survives for generic configurations of external momenta and was considered for MHV amplitudes in $[19]$ and for all tree level amplitudes in $[11, 8]$. The second term arises when two of the external momenta become collinear and was proposed in $[13]$ as the correction to the bare superconformal generator. The last two terms in (61) contribute already at tree level and were overlooked in the literature. In this subsection we shall explain for which configuration of external momenta they become relevant.

We shall start by $\bar{S}_{2\rightarrow 1}$. Whenever a subset of adjacent momenta becomes on-shell

$$(k_i + \cdots + k_{i+m-1})^2 = P^2 = 0,$$

the amplitude factorize as

$$A_n(k_1, \ldots, k_n) \to -i \int d^4L \int d^4\eta \mathcal{A}(L, k_i, \ldots, k_{i+m-1}) \frac{1}{L^2 + i0} \mathcal{A}(-L, m + i, \ldots, i - 1). \quad (64)$$

That property of scattering amplitude follows directly from the unitarity of the S-matrix and is called multi particle factorization. The right hand side of (64) is nothing but two disconnected amplitudes joined by our propagator inserting operator $\mathcal{L}$. When acting with $\bar{S}_{1\rightarrow 1}$, we can follow exactly the same steps as in the previous subsection (see figure 8). The result is therefore equal to $\bar{S}_{2\rightarrow 1}$ acting on two disconnected amplitudes. It is non-zero whenever $P$ become collinear to one of the neighboring momenta $k_i, k_{i-1}, k_{i+m}$ or $k_{i+m+1}$. The only difference from acting on a connected piece of the amplitude is the absence of additional propagators connecting the two sub-amplitudes. These however, played no role in our previous derivation.

---

24Similarly to $[\mathcal{L}, \bar{S}_{1\rightarrow 1}] = 0$, we have $[F, \bar{S}_{1\rightarrow 1}] = 0$ because (53) is a total derivative.
The action of the bare superconformal generator $\bar{S}_{1\rightarrow 1}$ on a tree level amplitude with a multi-particle pole. The result can be recast as $\bar{S}_{3\rightarrow 0}$ connecting three disconnected tree amplitudes. At one loop level the correction $\bar{S}_{3\rightarrow 0}$ plays a role at single multi-particle pole whereas starting from two loops this corrections becomes generically present (similarly to $\bar{S}_{2\rightarrow 1}$ at one loop).

The last contribution, $\bar{S}_{3\rightarrow 0}$, arises at a double multi particle pole

$$(k_i + \cdots + k_j)^2, (k_{j+1} + \cdots + k_l)^2 \rightarrow 0, \ i < j < l$$

where the two subset of null momenta also become collinear. The derivation of this correction follows precisely as before. When the bare generator acts on an amplitude with such kinematics the relevant CSW diagrams are those in figure 9. Two collinear legs are connected to one of the MHV vertices. The holomorphic anomaly associated with these two collinear legs generates a leg splitting operator $\bar{S}_{1\rightarrow 2}$ acting on an MHV vertex with one fewer leg. The two legs coming out of $\bar{S}_{1\rightarrow 2}$ are then connected to the other pieces of the graph. The sum over the three possible diagrams in figure 9 generates the correction $\bar{S}_{3\rightarrow 0}$ by exactly the same mechanism as explained in the main text.

6 Regularized Generators and Conformal Invariance of the Regularized S-matrix

In the previous section we have seen that formally, the S-matrix is superconformal invariant. That analysis was formal because $\mathcal{N}=4$ SYM is conformal and therefore doesn’t have asymptotic particles. However, the S-matrix observables we are interested in are IR safe quantities like an inclusive cross section. To compute these and argue for their superconformal covariance, one must first introduce an IR regulator. The IR regulated theory has an S-matrix from which the desired observables are computed. A good IR regulator is a regulator that drops out of IR safe physical quantities leaving a consistent answer behind.

---

25 At that point, due to momenta conservation, the remaining momenta $k_l + \cdots k_n$ will automatically become null and collinear with the two previous null subset of momenta.

26 This figure represents the relevant part of a bigger CSW graph, i.e. the dots could stand for extra propagators connecting to more MHV vertices.

27 The most commonly used regularization is dimensional regularization in which the external particles and helicities are kept four dimensional while the internal momenta are continued to $D = 4 - 2\epsilon$ dimensions.
In this section we will introduce an apparently new regularization scheme which we call sub-MHV regularization. The advantages of this regularization scheme are that it is “holomorphic anomaly friendly” and that the external momenta are treated in the same way as the internal ones.

It is important to keep in mind that IR safe quantities should exhibit the symmetries of the theory – in the case at hand superconformal symmetry – however we can have perfectly suitable regulators which break part of the symmetry when considering intermediate regulator dependent quantities. This is certainly the case for our proposal: we suggest a regulator which preserves the superconformal symmetry generated by $\bar{S}$; however the conjugate symmetry generated by $S$ (and therefore also special conformal transformations) will not be a symmetry of the regulated S-matrix. As for Lorentz invariance, the CSW procedure picks up a particular null momenta $\chi$ which can be thought of as a choice of light-cone gauge. The regularized S-matrix depends on $\chi$ and the Lorentz generators also rotate this vector. Similarly we could design a conjugate regularization which would preserve the symmetry spanned by $S$. Assuming our proposed regularization to be a good regulator, this implies that IR safe (regulator independent) quantities will be invariant under both $S$ and $\bar{S}$ (and therefore also $K$).

We saw before that in order to go from trees to loops it was quite useful to generalize scattering amplitudes to their tilded counterparts where external legs are put off-shell by means of the CSW prescription. These off-shell amplitudes appear quite naturally when we consider a sub-diagram inside a larger CSW expansion, (see figure 10). In this sub-diagram each “external” leg is

\[ (\text{where } \epsilon < 0). \]

It is a good regularization however, it smears the holomorphic anomaly which makes it hard to separate the correction to the generators from a conformal anomaly. Moreover, we have seen that the bare generators mixes internal momenta with external ones. Therefore, the regularized generator $\bar{S}_{2-1}$ for example, must act on an amplitude where the external momenta are treated in the same way as the internal ones (and therefore can carry momentum in the $-2\epsilon$ directions).

\[ \text{E.g. lattice regularization typically breaks most of the symmetries of the continuous theory and yet it is the regularization which (almost always) leads to the most reliable and rigorous results.} \]
characterized by a null momenta $l_i$ and an off-shell momenta $L_i = l_i + \delta y_i \chi$ such that

$$\sum_{j=1}^{n} \delta y_j = 0 ,$$

where $n$ is the number of “external” legs. For generic values of the of-shell shifts ($\delta y_j$) the sub-amplitudes obtained in this way are finite. This leads us to suggest a sub MHV regularization of scattering amplitudes: we replace any external (on-shell) momenta $l_i$ by an off-shell momenta of a small mass $m_i$ such that

$$l_i \rightarrow L_i = l_i + \delta y_i \chi , \quad \delta y_i = \frac{m_i^2}{2l_i \chi} ,$$

where $\chi$ is an arbitrary null momenta and (66) is imposed. The regulated amplitude is then given by the corresponding CSW sum where the external off-shell momenta are treated in the same footing as internal ones. Our proposal for the regulated S-matrix is just the same as considered before (48). The only difference is that now we use it to generate slightly off-shell (67) processes. That is, as internal $J$’s, all external $J$’s are functions of the on-shell momenta and superspace coordinate $\Lambda_i$ and the of-shellness parameter $y_i$. Notice that (66) automatically leaves the total momenta undeformed. Furthermore, it can be implemented at the level of the tree level functional \( \exp [\hat{A}_{c}^{(0)MHV} [J, \chi] \) because the propagator inserting operator $L$ always acts on legs with opposite $y$’s and thus does not spoil this condition.\(^{30}\)

It is instructive to understand what are the sources of divergence in one loop MHV amplitude (36) and why these are regulated by (67). For generic value of $y$, and after dressing out the tree level amplitude, the dLIPS integral in (36) computes the discontinuity of a one-loop amplitude in a multi-particle channel. The result is finite, unless $P_{L,y}$ is equal to a linear combination of two momenta adjacent to the cut (these are $k_i$, $k_{i+m-1}$, $k_{i+m}$ and $k_{i-1}$). Near such a point $y_*$, the dLIPS integral behaves as $\log (y - y_*)$. It will lead to a divergence of the $y$-integral only if $y_* = 0$, where the log singularity coincide with the simple pole in the measure. That is the case for $m = 1$ and $m = 2$ only.\(^{31}\) In both cases the divergences come from the region of the $y$-integration near $y = 0$ where the integrand behaves as $\log \frac{y-y_0}{y+y_0}$. For $m = 1$, the point $y = 0$ is also the limit of integration (this means that the divergences from both sides of the pole do not cancel each other and therefore the $m = 1$ term diverges more severely than the $m = 2$ contribution). For $m = 2$, the point $y = 0$ is not the limit of integration however the contour of integration is trapped between the log and the pole singularities. After regularization (67), the simple pole and the log singularity are separated by $\delta y_i$ for $m = 1$ and by $\delta y_i + \delta y_{i+1}$ for $m = 2$. Moreover, for $m = 1$ the location of the simple pole differ from the bottom limit of integration by $\delta y_i$. The resulting integrals (with i0 prescription) are therefore finite.

In what follows, we will assume MHV sub regularization to be a good regularization.\(^{32}\) We will now show that the superconformal generator $\hat{S}$ can be easily deformed in such a way that it is still a symmetry of the regularized S-matrix.

---

\(^{29}\)The mass $m_i$ is taken small with respect to the amplitude Lorentz invariants.

\(^{30}\)We expect that up to sub-leading terms in the regulator, this regularization is equivalent to the more conventional regularization in which the external particles are given a small mass $m_i$.

\(^{31}\)Other than that, the simple pole at $y = 0$ (with an i0 prescription) can lead to a divergence only if $y = 0$ is a limit of integration. That is the case for $m = 1$ only. We conclude that before regularization, the only divergent integrals in the sum (36) are the ones with $m = 1$ and $m = 2$.

\(^{32}\)We plan to consider this regularization in greater detail elsewhere.
The derivation of the regulated generators follows exactly the same steps as in the previous formal section. The only difference is that now the external momenta also carry an off-shell component parametrized by $\delta y_i$ (67). Again, since MHV mass regularization leaves the MHV vertices untouched, so are the holomorphic anomalies. The resulting regularized form of the generators $\bar{S}_{1\to 1}$ and $\bar{S}_{2\to 1}$ are almost identical to their on-shell counterparts and read

$$(\bar{S}_{1\to 1})_{Reg} = -\sum_{s=\pm} s \int d^4\Lambda dy \eta \text{Tr} \left[ \partial \tilde{J}(\Lambda^s_y) \tilde{J}(\Lambda^s_y) \right]$$

$$(\bar{S}_{2\to 1})_{Reg} = \pi \sum_{s,s_1,s_2=\pm} \int d^4\Lambda d^4\eta' d\alpha dy' \bar{\lambda} \eta' \times \int dy' \left[ \frac{i}{y' + y + i0} - \frac{i}{y' - s_1 s_2 i0} \right] \text{Tr} \left[ J(\Lambda^s_{1,y'}) \tilde{J}(\Lambda^{s_1}_{1,y+y}) \tilde{J}(\Lambda^{s_2}_{2,-y'}) \right].$$

When acting with $(\bar{S}_{2\to 1})_{Reg}$ on the regularized amplitude a new loop is formed. In that loop, $y$ is the off-shell regulator. For any non zero value of $y$, we don’t have the cancelation obtained in the formal discussion around (55). Instead, $(\bar{S}_{2\to 1})_{Reg}$ is connected to the amplitude by the difference between two off-shell propagators. As we try to remove the regulator, these propagators become more and more concentrated around the on-shell point. The generator $\bar{S}_{3\to 0}$ does not involve external legs and therefore stands as it is (60) after regularization; the off-shell generator $\bar{S}_{1\to 2}$ is given in (52). We conclude that the formal structure obtained in the previous section survives regularization.

It would be very interesting to repeat our analysis, both formal and regularized, for the dual conformal symmetry. We expect to be able to prove, under the same assumptions in this paper, dual conformal invariance of scattering amplitudes at any loop order. Furthermore, it would be very interesting to understand how these two symmetries combine into a Yangian at loop level. Finally, an obvious question is of course to which extent can we use all these symmetries for computational purposes. We plan to address these issues in a separate publication.

Acknowledgements

We would like to thank N.Beisert, N.Gromov, J.Henn, V.Kazakov, T.McLoughlin, J.Penedones, J.Plefka and D. Skinner for interesting discussions. We would specially like to thank F.Cachazo for many enlightening discussions, suggestions and for referring us to many relevant references. The research of AS has been supported in part by the Province of Ontario through ERA grant ER 06-02-293. PV thanks the Perimeter Institute for warm hospitality during the concluding part of this work.

A Appendix. The $m = 1$ case

The MHV one loop amplitude when written as a sum of dispersion integrals contains some peculiar terms – depicted in figure 11 – where a single external particle on the left is connected by a 3-MHV vertex to the remaining $n - 1$ external particles in a tree level amplitude $A_{n+1}$. When acting with $\bar{S}_{1\to 1}$ on these contributions we will again set the internal lines $l_1$ or $l_2$ to be collinear to one of the external legs: either the leg $i$ on the left or one of the legs $i - 1$ or $i + 1$ on the right. The latter
In this appendix we explain that these contributions might set one of the internal momenta to be collinear with some external leg. Cutting the internal leg in this way would generate bivalent MHV vertices. In appendix A we explain that these contributions actually vanish.

case poses no problem: e.g. when we cut the line $l_1$ making it collinear with $i + 1$ we obtain a three vertex on the left connected with a $A_n$ amplitude on the right; this case is covered in the main text. Much more problematic at first sight is the former contribution: if $l_1$ becomes collinear to $i$ then naively we will obtain a bivalent MHV vertex on the left connected to a $A_{n+1}$. Bivalent vertices are of course not present in the CSW rules and this could cause a problem.\footnote{See also section A subtle detail in \cite{20}} In this appendix we will consider these contributions and explain that they actually vanish.

Without loss of generality let us take $i = 1$. We need to collect from

$$A_n^{(0)} \int \frac{dy}{y + i0} \int d^4 l_1 d^4 l_2 \delta^{(+)}(l_1^2) \delta^{(+)}(l_2^2) \delta^4(k_1 - (y - y') \chi - l_1 - l_2) \int d^4 \eta_1 d^4 \eta_2 \delta^8(Q_R - Q_l)$$

$$\left(S_L + S_R + S_{l_1, l_2}\right) \frac{\langle n 1 | 12 \rangle}{(l_1) \langle l_1 | l_2 \rangle} \frac{\langle n 1 | 12 \rangle \langle l_1 l_2 \rangle^2}{(2 l_1) \langle n l_2 \rangle}$$

the terms where an internal momentum becomes collinear to $k_1$. Recall that in our regularization each leg has some $y_j$ which measures the particle off-shellness; $y_1 \equiv y'$. Preforming the Grassmanian integrations we find the following expression for those terms:

$$\frac{4\pi^2 \imath c(\epsilon)}{\sin(\pi \epsilon)} A_n^{(0)} \eta_1 \int \frac{dy}{y + i0} \int d^4 l_1 d^4 l_2 \delta^{(+)}(l_1^2) \delta^{(+)}(l_2^2) \delta^4(k_1 - (y - y') \chi - l_1 - l_2) \frac{\langle n 1 | 12 \rangle \langle l_1 l_2 \rangle^2}{(2 l_1) \langle n l_2 \rangle}$$

$$\times \left( \left( \frac{\langle l_1 l_2 \rangle}{\langle l_1 \rangle \langle l_2 \rangle} \frac{l_1}{(12)} - \frac{l_2}{\langle l_1 \rangle \langle l_2 \rangle} \frac{l_2}{\langle l_1 \rangle \langle l_2 \rangle} \right)^2 (\langle 1 l_1 \rangle) + \left( \frac{l_1 l_2}{\langle l_1 \rangle \langle l_2 \rangle} - \frac{l_1}{\langle l_1 \rangle \langle l_2 \rangle} \frac{l_2}{\langle l_1 \rangle \langle l_2 \rangle} \right)^2 (\langle 1 l_2 \rangle) + 2 \left( \frac{l_1 l_2}{\langle l_1 \rangle \langle l_2 \rangle} - \frac{l_1}{\langle l_1 \rangle \langle l_2 \rangle} \frac{l_2}{\langle l_1 \rangle \langle l_2 \rangle} \right)^2 (\langle 1 l_2 \rangle) \right) \quad (70)$$

We will now see that each of the three terms inside the parentheses leads to a vanishing expression by itself. We start by considering the first term. Preforming the integration over $l_2$ using the momentum conservation delta function we see that this term is proportional to

$$\int \frac{dy}{y + i0} \int d^4 l_1 \delta^{(+)}(l_1^2) \delta^{(+)}(l_2^2) \frac{l_1 l_2}{\langle 2 l_1 \rangle \langle n l_2 \rangle \langle l_2 \rangle} \frac{\langle l_1 l_2 \rangle}{\langle l_1 \rangle \langle l_2 \rangle} \left( \langle 1 l_2 \rangle \frac{l_1}{\langle l_1 \rangle \langle l_2 \rangle} - \langle 1 l_2 \rangle \frac{l_1}{\langle l_1 \rangle \langle l_2 \rangle} \right)^2 (\langle 1 l_1 \rangle) \quad (71)$$

where $l_2 = k_1 - (y - y') \chi - l_1$. Next we use the delta function $\delta^2(\langle 1 l_1 \rangle)$ to set $l_1 = t k_1$. The previous integral is then proportional to

$$\frac{dy}{y + i0} \int d t (1 - t) \frac{y \langle 1 \chi | \rho \rangle (1 - t) \langle n | k_1 \rho \rangle - y \langle n | \chi | \rho \rangle}{(1 - t) \langle n | k_1 \rho \rangle - y \langle n | \chi | \rho \rangle} \delta(y (1 - t)) = 0 \quad (72)$$

\footnote{See also section A subtle detail in \cite{20}}
Here $\rho$ is an arbitrary spinor used to simplify
\[
\frac{\langle 1l_2 \rangle}{\langle nl_2 \rangle} = \frac{\langle 1l_2 \rangle |l_2\rangle}{\langle nl_2 \rangle |l_2\rangle} = \frac{-y \langle 1|\chi|\rho \rangle}{(1 - t)\langle n|k_1|\rho \rangle - y \langle n|\chi|\rho \rangle}
\]
and changed variables from $y - y' \rightarrow y$. Notice that without the $y'$ regularization the integral (72) would be ill defined as mentioned in the main text. The second term in (70) is treated similarly.

This leaves us with the last term, proportional to $\delta^2(\langle l_1l_2 \rangle)$. We first use (twice) the Schouten identity to re-write the spinor ratio pre-factor as:
\[
C \equiv \frac{\langle 12 \rangle |1n\rangle |l_1l_2 \rangle^2}{\langle 1l_1 \rangle |2l_1\rangle |l_2n \rangle |l_2 \rangle} = \frac{-2 \langle l_2 \rangle |n\rangle |l_1 \rangle}{\langle 2l_1 \rangle |l_1 \rangle |l_2 \rangle |n \rangle} + \frac{-\langle 1l_2 \rangle |n\rangle |l_1 \rangle}{\langle 1l_1 \rangle |l_1 \rangle |l_2 \rangle |n \rangle} + \frac{\langle 1l_1 \rangle |2l_2 \rangle}{\langle 1l_1 \rangle |l_1 \rangle |l_2 \rangle |2l_1 \rangle} - 1
\]

Notice that for $l_1 \propto l_2$ each term is either 1 or $-1$ and the sum of all terms is zero. With the off-shell regularization the remaining terms do not lead to divergencies and therefore this contribution also vanishes.
