Radiative seesaw corrections and charged-lepton decays in a model with soft flavour violation

E.H. Aeikens, P.M. Ferreira, W. Grimus, D. Jurčiukonis and L. Lavoura

Abstract: We consider the one-loop radiative corrections to the light-neutrino mass matrix and their consequences for the predicted branching ratios of the five lepton-flavour-violating decays $\ell_1^- \rightarrow \ell_2^- \ell_3^+ \ell_4^-$ in a two-Higgs-doublet model furnished with the type-I seesaw mechanism and soft lepton-flavour violation. We find that the radiative corrections are very significant; they may alter the predicted branching ratios by several orders of magnitude and, in particular, they may help explain why BR $(\mu^- \rightarrow e^- e^+ e^-)$ is strongly suppressed relative to the branching ratios of the decays of the $\tau^-$. We conclude that, in any serious numerical assessment of the predictions of this model, it is absolutely necessary to take into account the one-loop radiative corrections to the light-neutrino mass matrix.

Keywords: Phenomenological Models

ArXiv ePrint: 2009.13479
1 Introduction

The existence of neutrino oscillations is now firmly established — see [1–4] and references therein. Therefore, the violation of the family lepton numbers $L_\ell$ ($\ell = e, \mu, \tau$) is firmly established as well. However, no violation of the $L_\ell$ but for neutrino oscillations has been hitherto detected. In this context, the flavour-violating charged-lepton decays are of particular importance, because it is expected that in the near future the experimental bounds on the branching ratios (BRs) of those decays will be improved substantially [5–9] (see also section 2 of [10]). It is thus important to address those decays in specific models for the neutrino masses and lepton mixings — and the more so since, when one incorporates neutrino masses and lepton mixings in the Standard Model (SM), those BRs are so small that the decays are in practice invisible [11–14].
In this letter we discuss the model put forward in [15, 16]. This is in general a multi-Higgs-doublet extension of the SM (for reviews see [17, 18]), but we confine ourselves to just two Higgs doublets. The model has three right-handed neutrino singlets $\nu R$ that enable the seesaw mechanism [19–23]. The lepton Yukawa couplings are

$$\mathcal{L}_{\text{Yukawa}} = - \sum_{\ell_1, \ell_2 = e, \mu, \tau} \left[ \left( \varphi_1^0, \varphi_1^0 * \right) \bar{\ell}_1 R \left( Y_1 \right) \ell_1 \ell_2 + \left( \varphi_0^0, -\varphi_1^+ \right) \bar{\nu}_1 R \left( Z_1 \right) \ell_1 \ell_2 \right]$$

$$+ \left( \varphi_2^0, \varphi_2^0 * \right) \bar{\ell}_1 R \left( Y_2 \right) \ell_1 \ell_2 + \left( \varphi_2^0, -\varphi_2^+ \right) \bar{\nu}_1 R \left( Z_2 \right) \ell_1 \ell_2 \right] \left( \nu_{\ell L} \ell_{\ell L} \right) + \text{H.c.}, \quad (1.1)$$

where $Y_{1,2}$ and $Z_{1,2}$ are Yukawa-coupling matrices. A crucial feature of the model is the imposition of three global $U(1)_\ell$ symmetries associated with the family lepton numbers $L_\ell$; those symmetries force $Y_{1,2}$ and $Z_{1,2}$ to be diagonal. (The lepton numbers of the two Higgs doublets are zero.) Without loss of generality, in this letter we use the ‘Higgs basis’, wherein only the first doublet has a nonzero vacuum expectation value $v / \sqrt{2}$, where $v \simeq 246$ GeV is real and positive, in its neutral component $\varphi_0^0$. This allows us to rewrite (1.1) as

$$\mathcal{L}_{\text{Yukawa}} = - \sum_{\ell = e, \mu, \tau} \left[ \left( \varphi_1^0, \varphi_1^0 * \right) \bar{\ell}_R \frac{\sqrt{2} m_\ell}{v} + \left( \varphi_0^0, -\varphi_1^+ \right) \bar{\nu}_R d_\ell \right]$$

$$+ \left( \varphi_2^0, \varphi_2^0 * \right) \bar{\ell}_R \gamma_\ell + \left( \varphi_2^0, -\varphi_2^+ \right) \bar{\nu}_R \delta_\ell \right] \left( \nu_{\ell L} \ell_{\ell L} \right) + \text{H.c.}, \quad (1.2)$$

where the $m_\ell$ are the (real and positive) charged-lepton masses and $d_\ell$, $\gamma_\ell$, and $\delta_\ell$ are dimensionless and, in general, complex Yukawa coupling constants.

In our model the source of lepton-flavour violation lies exclusively in the Majorana mass matrix $M_R$ of the right-handed neutrinos. In other words, the only lepton-flavour-violating (LFV) terms in the Lagrangian are in

$$\mathcal{L}_{\nu R \text{ mass}} = - \frac{1}{2} \sum_{\ell_1, \ell_2 = e, \mu, \tau} \left( M_R \right)_{\ell_1 \ell_2} \bar{\nu}_{\ell_1 R} C \bar{\nu}_{\ell_2 R} + \text{H.c.}, \quad (1.3)$$

where $(M_R)_{\ell_1 \ell_2} = (M_R)_{\ell_2 \ell_1}$ are coefficients with mass dimension and $C$ is the charge-conjugation matrix in Dirac space. The salient feature of this model is the soft nature of the breaking of the $L_\ell$ [15, 24] by $\mathcal{L}_{\nu R \text{ mass}}$. Soft-breaking of a symmetry means that the symmetry is preserved by dimension-four terms in the Lagrangian, viz. the Yukawa couplings (1.2), but it is broken by terms with mass dimension smaller than four, viz. the Majorana masses (1.3). In our model, the softness of the breaking ensures that the one-loop amplitudes of LFV charged-lepton decays are finite, as was explicitly demonstrated by two of us in [15].

---

1This mechanism for suppressing undesirable flavour-changing neutral currents has no counterpart in the quark sector. Since we do not want to set to zero any of the Yukawa couplings in (1.2), the two Higgs doublets cannot transform non-trivially under any global symmetry. Therefore, at this stage, we can only resort to finetuning in the quark sector. In the present letter we shall not address this issue any further.
Let \( S^\pm_a \) (\( a = 1, 2 \)) and \( S^0_b \) (\( b = 1, 2, 3, 4 \)) denote, respectively, the charged-scalar and the (real) neutral-scalar mass eigenfields of our two-Higgs-doublet model (2HDM). By definition, \( S^+_1 \equiv G^+ \) and \( S^0_1 \equiv G^0 \) are, respectively, the charged and the neutral Goldstone bosons. Again by definition, \( S^0_2 \equiv H \) is the physical scalar with mass \( m_H \approx 125 \) GeV that has been observed at the LHC. Let \( M_3 \) and \( M_4 \) denote the masses of \( S^0_3 \) and \( S^0_4 \), respectively.

It is an outstanding feature of our model that the amplitudes for the radiative decays \( \ell^+_1 \to \ell^+_2 \gamma \) and \( Z^0 \to \ell^+_1 \ell^-_2 \) (\( \ell_1 \neq \ell_2 \)) are suppressed by \( m_R^{-2} \), where \( m_R \) is the seesaw scale [15]; one can estimate that for \( m_R \gtrsim 10^3 \) TeV these decays are invisible, in the foreseeable future, in the context of our model [16] (another model with this feature is discussed in [25]). The same suppression occurs when the gauge bosons are off-mass shell, \( \nu \). In the one-loop diagrams for the LFV decays \( \mu^- \to e^- e^+ e^- \) and \( \tau^- \to \ell^-_2 \ell^-_3 \ell^-_3 \) (\( \ell_2, \ell_3 = e, \mu \)) [15] where those decays are mediated by either a virtual \( \gamma \) or a virtual \( Z^0 \). On the other hand, those five decays also have one-loop amplitudes mediated by neutral-scalar exchange, and these amplitudes are unsuppressed when \( m_R \to \infty \) [15]. It is the purpose of this letter to present a theoretical and numerical study of these three-body decays while taking into account the radiative corrections to the seesaw mass matrix of the light neutrinos [26]. The latter point is new when compared to [16], and it is important because of two reasons:

- For \( M_3 \) or \( M_4 \) larger than \( 4\pi v \approx 3 \) TeV, and provided the Yukawa couplings \( d_i \) and \( \delta\nu \) are of similar order of magnitude, the radiative corrections to the neutrino mass matrix are dominant;\(^3\) they are non-negligible even for values of \( M_{3,4} \) much lower than that.

- The branching ratios \( \text{BR} \left( \ell^-_1 \to \ell^-_2 \ell^-_3 \ell^-_3 \right) \) depend on the mass matrix \( M_R \) [15, 16] — see section 2. Information on \( M_R \) is not directly available but has to be extracted from the mass matrix of the light neutrinos. The latter matrix may be assembled from the light-neutrino masses and from the lepton mixing obtained from fits to the neutrino oscillation data. Therefore, the radiative corrections to the mass matrix of the light neutrinos will influence the extraction of \( M_R \). Indeed, they may alter the branching ratios drastically, as we shall see later.

Henceforth, for the sake of brevity, the acronym ‘BR’ will always refer to the branching ratios of the five decays \( \ell^-_1 \to \ell^-_2 \ell^-_3 \ell^-_3 \); the same will apply to the phrase ‘decay rate’.

Although in this letter we consider just a 2HDM, we nevertheless have a large number of parameters. In order to facilitate the numerical analysis it is useful to reduce that number. We adopt the strategy of [16] and assume the following:

A. There is no mixing between the two scalar doublets.

B. All parameters are real.

\(^2\)The box diagrams for \( \mu^- \to e^- e^+ e^- \) and \( \tau^- \to \ell^-_2 \ell^-_3 \ell^-_3 \) are also suppressed by \( 1/m_R^2 \) [15].

\(^3\)It was already stressed in [27] (see also [28, 29]) that the radiative corrections to the seesaw mechanism, in the presence of two or more Higgs doublets and heavy neutral scalars, may be quite large. Moreover, it has been demonstrated in [30] that, even with only one Higgs doublet, those corrections may be substantial for fine-tuned tree-level neutrino mass matrices.
Through assumption A, the mixing of the scalars is simplified to [16]

\[ \phi_1^+ = G^+, \quad \phi_2^+ = H^+, \quad \phi_1^0 = \frac{v + H + iG^0}{\sqrt{2}}, \quad \phi_2^0 = e^{-i\alpha} \frac{S_0^0}{\sqrt{2}} + \frac{iS_4^0}{\sqrt{2}}, \quad (1.4) \]

where \( H^+ \) is a physical charged scalar which, however, plays no role in this letter. The advantage of assumption A is threefold:

- There are in general three parameters in the mixing of the neutral scalars [16, 31]. With assumption A they are reduced to only one — the phase \( \alpha \), which is, however, unphysical because one may freely rephase \( \phi_2^+ \) and \( \phi_2^0 \).
- The formulas for the BRs simplify considerably (see section 3).
- The couplings of \( H \) are identical to the ones in the SM, hence the experimental restrictions on the couplings of \( H \) are automatically fulfilled.

We thus consider that we are in the exact alignment limit of the 2HDM. This is in accordance with the measurements of the properties of the scalar discovered at LHC (see for instance [32, 33]), which have found that that scalar behaves in a manner very similar to the SM Higgs boson; its couplings are experimentally constrained to be very close to their respective SM values [34]. Assumption A ensures that this indeed happens in our 2HDM. In the ensuing discussions we will initially keep complex parameters, but we take into account assumption A right from the beginning.

This letter is organized as follows. In section 2 we discuss the light-neutrino mass matrix, including the radiative corrections. The formulas for the decay rates are displayed in section 3, where we also derive a prediction of our model when assumption A holds. In section 4 we discuss the procedure of our numerical investigation and in section 5 some results thereof are presented. We draw our conclusions in section 6. An appendix makes a digression through the scalar potential of the 2HDM in order to demonstrate that the two new scalars \( S_0^3 \) and \( S_4^0 \) may have sufficiently different masses.

2 The light-neutrino mass matrix

The Majorana mass matrix \( M_{\nu} \) of the light neutrinos is diagonalized as

\[ U_L^T M_{\nu} U_L = \tilde{m} \equiv \text{diag} (m_1, m_2, m_3), \quad (2.1) \]

where \( U_L \) is \( 3 \times 3 \) unitary and the \( m_j \) (\( j = 1, 2, 3 \)) are real and non-negative. Since the charged-lepton mass matrix is diagonal from the start, cf. \( (1.2) \), \( U_L \) is just the lepton mixing matrix. The matrix \( M_R \), defined in \( (1.3) \), is diagonalized as

\[ U_R^T M_R U_R^* = \tilde{m} \equiv \text{diag} (m_4, m_5, m_6), \quad (2.2) \]

\[ ^{4}\text{Due to assumption B, later on we will set } e^{-i\alpha} = 1 \text{ in (1.4).} \]
where the $m_{3+j}$ are real and positive and the matrix $U_R$ is $3 \times 3$ unitary. For the decay rates — see (3.1) in the next section — we need the quantities \cite{15, 16} 

$$X_{\ell_1\ell_2} = \frac{1}{10\sqrt{2}\pi} \sum_{j=1}^{3} (U_R)_{\ell_1 j} (U_R^*)_{\ell_2 j} \ln \frac{m_{3+j}}{\mu^2}$$  \hfill (2.3)

for $\ell_1 \neq \ell_2$.\footnote{The renormalization scale $\mu$ that renders the argument of the logarithm dimensionless is arbitrary, since $U_R$ is unitary and only the case $l_1 \neq l_2$ is considered in this work.} This requires us to know both $U_R$ and the heavy-neutrino masses $m_{4,5,6}$. Note that, since $U_R$ is a $3 \times 3$ unitary matrix, $X_{\ell_1\ell_2}$ cannot be large; one has $|X_{\ell_1\ell_2}| \lesssim 0.1$ if $10^9 \text{GeV} \leq m_{4,5,6} \leq 10^{19} \text{GeV}$.

We parameterize $U_L$ as

$$U_L = e^{i\hat{\alpha}} U_{\text{PMNS}} e^{i\hat{\beta}},$$  \hfill (2.4a)

$$U_{\text{PMNS}} = \begin{pmatrix}
    c_{12} c_{13} & s_{12} c_{13} & \epsilon^* \\
    -s_{12} c_{23} - c_{12} s_{23} \epsilon & c_{12} c_{23} - s_{12} s_{23} \epsilon & s_{23} c_{13} \\
    s_{12} s_{23} - c_{12} c_{23} \epsilon & -c_{12} s_{23} - s_{12} c_{23} \epsilon & c_{23} c_{13}
\end{pmatrix},$$  \hfill (2.4b)

$$\epsilon \equiv s_{13} \exp (i\delta).$$  \hfill (2.4c)

In (2.4a), $e^{i\hat{\alpha}}$ and $e^{i\hat{\beta}}$ are diagonal matrices of phase factors while $U_{\text{PMNS}}$ is the Pontecorvo-Maki-Nakagawa-Sakata matrix \cite{4}. Out of the three phases in $e^{i\hat{\beta}}$, one may be absorbed into $\hat{\alpha}$ and the remaining two are the so-called Majorana phases, which are physically meaningful quantities. In (2.4b) and (2.4c), $c_{ij} = \cos \theta_{ij}$ and $s_{ij} = \sin \theta_{ij}$ for $ij = 12, 13, 23$, and $\delta$ is a CP-violating phase. The matrix $U_R$ may be parameterized in the same way as $U_L$.

The matrix $M_\nu$ is the sum of two parts:

$$M_\nu = M_\nu^{\text{tree}} + \delta M_L,$$  \hfill (2.5)

where the tree-level part $M_\nu^{\text{tree}}$ is given by the seesaw mechanism and the one-loop-level part $\delta M_L$ is generated by the radiative corrections. As is well known,

$$M_\nu^{\text{tree}} = -M_D M_R^{-1} M_D,$$  \hfill (2.6)

where $M_D$ is the neutrino Dirac mass matrix. Referring to (1.2), let us define the diagonal matrices

$$\Delta_1 = \text{diag} (d_e, d_\mu, d_\tau) \quad \text{and} \quad \Delta_2 = \text{diag} (\delta_e, \delta_\mu, \delta_\tau).$$  \hfill (2.7)

Because we use the Higgs basis, $M_D$ is given by

$$M_D = \frac{v}{\sqrt{2}} \Delta_1,$$  \hfill (2.8)

hence it is diagonal. Thus,

$$M_\nu^{\text{tree}} = -\frac{v^2}{2} \Delta_1 U_R^* \frac{1}{m} U_R^\dagger \Delta_1.$$  \hfill (2.9)
The radiative part of $\mathcal{M}_\nu$ is given by [26]

$$
\delta M_L = \frac{3 m_3^2}{12 \pi^2} \Delta_1 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{m_Z} \right) U_R^\dagger \Delta_1 
$$

$$
+ \frac{m_3^2}{32 \pi^2} \Delta_1 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{m_H} \right) U_R^\dagger \Delta_1 
$$

$$
+ \frac{M_3^2}{32 \pi^2} e^{-2i \alpha} \Delta_2 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{M_3^2} \right) U_R^\dagger \Delta_2 
$$

$$
- \frac{M_4^2}{32 \pi^2} e^{-2i \alpha} \Delta_2 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{M_4^2} \right) U_R^\dagger \Delta_2, 
$$

where the four lines correspond successively to the contribution of the $Z^0$ gauge boson with mass $m_Z$, of the SM scalar $H$, and of the new scalars $S_0^0$ and $S_1^0$. In (2.10) we have already taken into account assumption A of section 1. We have also used $m_{4,5,6} \gg m_Z, m_H, M_{3,4}$. It is clear that for $M_{3,4} \geq 4\pi v$ and provided $\Delta_1$ and $\Delta_2$ are of identical orders of magnitude, the contributions (2.10c) and (2.10d) dominate over the contribution (2.9) provided $M_3 \neq M_4$. Lines (2.10c) and (2.10d) coincide with the well-known scotogenic mechanism; however, in the scotogenic model proper [35] the Yukawa couplings $d_\ell$ and $\gamma_\ell$ are zero (because of an additional symmetry), while in this letter they are nonzero.

We reformulate (2.1) to

$$
e^{-i \alpha} U_{\text{PMNS}}^\dagger (\tilde{m} e^{-2i \beta}) U_{\text{PMNS}}^\dagger e^{-i \alpha} = -\frac{v^2}{2} \Delta_1 U_R^\dagger \frac{1}{m} U_R^\dagger \Delta_1 
$$

$$
+ \frac{3 m_3^2}{32 \pi^2} \Delta_1 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{m_Z} \right) U_R^\dagger \Delta_1 
$$

$$
+ \frac{m_3^2}{32 \pi^2} \Delta_1 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{m_H} \right) U_R^\dagger \Delta_1 
$$

$$
+ \frac{M_3^2}{32 \pi^2} e^{-2i \alpha} \Delta_2 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{M_3^2} \right) U_R^\dagger \Delta_2 
$$

$$
- \frac{M_4^2}{32 \pi^2} e^{-2i \alpha} \Delta_2 U_R^\dagger \left( \frac{1}{m} \ln \frac{\tilde{m}_2}{M_4^2} \right) U_R^\dagger \Delta_2. 
$$

Equation (2.11) is the basis for our numerical computations.

The diagonal matrix $e^{i \alpha}$ in the left-hand side of (2.11) is irrelevant; indeed, it can be absorbed into $U_R$ in the right-hand side, since $\Delta_1$ and $\Delta_2$ are diagonal matrices. In principle we use as input the Majorana phases, $U_{\text{PMNS}}, \tilde{m}, \Delta_1, \Delta_2, \alpha$, $M_3$, and $M_4$ (and additionally the fixed values $v = 246$ GeV, $m_Z = 91$ GeV, and $m_H = 125$ GeV) and we solve (2.11) to find the three $m_{3+j}$ and the nine parameters of the $3 \times 3$ unitary matrix $U_R$. All the matrices in (2.11) are $3 \times 3$ symmetric and complex; therefore, equation (2.11) is in effect a system of 12 real equations for the 12 unknowns — $m_{4,5,6}$ and the nine parameters of $U_R$ — that we need for the computation of the $X_{\ell_1 \ell_2}$. We stress that this parameter counting only serves to demonstrate the theoretical possibility of obtaining the $X_{\ell_1 \ell_2}$ from equation (2.11); when one attempts to do it numerically, equation (2.11) may sometimes prove difficult or impossible to solve.

---

The large logarithms of $m_{3+j}/M_{3,4}$ further enhance the contributions (2.10c) and (2.10d).

---

The large logarithms of $m_{3+j}/M_{3,4}$ further enhance the contributions (2.10c) and (2.10d).
In practice, we reduce the number of parameters by applying assumption B, i.e. the reality assumption. Concretely, we set
\[ e^{-i\alpha} = e^{-2i\beta} = 1, \quad (2.12a) \]
\[ e^{i\delta} = -1 \text{ in } U_{PMNS}, \quad (2.12b) \]
\[ e^{-2i\alpha} = 1, \quad (2.12c) \]
\[ d_\ell \text{ real (} \ell = e, \mu, \tau), \quad (2.12d) \]
\[ \delta_\ell \text{ real (} \ell = e, \mu, \tau). \quad (2.12e) \]

In (2.12b) we have opted for \( \delta = \pi \), which is phenomenologically preferred over \( \delta = 0 [36–39] \). Using the assumptions (2.12), the symmetric matrix in the left-hand side of (2.11) is real, hence it has just six degrees of freedom. Then, the matrix \( U_R \) may be written
\[ U_R = U'_R \times \text{diag} (\epsilon_4, \epsilon_5, \epsilon_6), \quad (2.13) \]
where \( U'_R \in SO(3) \) is a real matrix parameterized by three angles and the \( \epsilon_{3+j} \) may be either 1 or \( i \). Equation (2.11) is then used to determine the three angles of \( U'_R \) and the three \( \epsilon^2_{3+j} m_{3+j} \); the latter are either positive, if \( \epsilon_{3+j} = 1 \), or negative, if \( \epsilon_{3+j} = i \).

Let us take stock of the (real) parameters in the game, after having performed the simplification stated in the previous paragraph. From the neutrino oscillation data, both the two mass-squared differences among the three light-neutrino masses and the three mixing angles in \( U_{PMNS} \) are known and they are used as input. There are then 15 unknown parameters in (2.11): the lightest neutrino mass, \textit{viz.} \( m_1 \) for normal ordering and \( m_3 \) for inverted ordering of the neutrino masses, \( M_{3,4}, d_\ell, \delta_\ell, \epsilon^2_{3+j} m_{3+j} \) for \( j = 1, 2, 3 \), and the three angles in \( U_R \). As we shall see in the next section, there are in addition the three parameters \( \gamma_\ell \), which do not appear in (2.11) but occur in the BRs.

### 3 Decay rates

Repeating the result of [16], the decay rates are given by
\[ \Gamma (\mu^- \rightarrow e^- e^+ e^-) = \frac{m_\mu}{6144\pi^3} \left[ \frac{3}{4} \left( \frac{1}{M_3^2} + \frac{1}{M_4^2} \right) + \frac{1}{2M_3^2 M_4^2} \right] \times |X_{\mu e}|^2 |\gamma_\ell|^2 \left( |A_{\mu e}|^2 + |A_{e\mu}|^2 \right), \quad (3.1a) \]
\[ \Gamma (\tau^- \rightarrow e^- e^+ e^-) = \frac{m_\tau}{6144\pi^3} \left[ \frac{3}{4} \left( \frac{1}{M_3^2} + \frac{1}{M_4^2} \right) + \frac{1}{2M_3^2 M_4^2} \right] \times |X_{\tau e}|^2 |\gamma_\ell|^2 \left( |A_{\tau e}|^2 + |A_{e\tau}|^2 \right), \quad (3.1b) \]
\[ \Gamma (\tau^- \rightarrow \mu^- \mu^+ \mu^-) = \frac{m_\tau}{6144\pi^3} \left[ \frac{3}{4} \left( \frac{1}{M_3^2} + \frac{1}{M_4^2} \right) + \frac{1}{2M_3^2 M_4^2} \right] \times |X_{\tau \mu}|^2 |\gamma_\ell|^2 \left( |A_{\tau \mu}|^2 + |A_{\mu \tau}|^2 \right), \quad (3.1c) \]
\[ \Gamma (\tau^- \rightarrow \mu^- \mu^+ \mu^-) = \frac{m_\tau}{6144\pi^3} \left[ \frac{3}{4} \left( \frac{1}{M_3^2} + \frac{1}{M_4^2} \right) + \frac{1}{2M_3^2 M_4^2} \right] \times |X_{\tau \mu}|^2 |\gamma_\ell|^2 \left( |A_{\tau \mu}|^2 + |A_{\mu \tau}|^2 \right), \quad (3.1d) \]
\[ \Gamma (\tau^- \rightarrow \mu^- e^+ e^-) = \frac{m_\tau}{6144\pi^3} \left( \frac{1}{M_3^2} + \frac{1}{M_4^2} \right) |X_{\tau \mu}|^2 |\gamma_\ell|^2 \left( |A_{\tau \mu}|^2 + |A_{\mu \tau}|^2 \right), \quad (3.1e) \]
where we have used the approximation that the final-state charged leptons are massless, and

\[
A_{\ell_1,\ell_2} = \frac{\sqrt{2}}{\nu} \left( m_{\ell_1}^2 - m_{\ell_2}^2 \right) m_{\ell_1} \delta_{\ell_1}^* d_{\ell_2} + m_{\ell_2} \gamma_{\ell_1} (\delta_{\ell_1}^* \delta_{\ell_2} - d_{\ell_1}^* d_{\ell_2}) + \frac{m_{\ell_1} m_{\ell_2}}{2} \gamma_{\ell_2} \left( 3 d_{\ell_1}^* d_{\ell_2} - \delta_{\ell_1}^* \delta_{\ell_2} \right) - \frac{m_{\ell_2}^2}{2} \gamma_{\ell_1} (\delta_{\ell_1}^* \delta_{\ell_2} + d_{\ell_1}^* d_{\ell_2}) + \frac{\nu}{\sqrt{2}} m_{\ell_1} \left( \delta_{\ell_1}^* |\gamma_{\ell_2}|^2 d_{\ell_2} - \gamma_{\ell_2}^2 \delta_{\ell_1}^* \delta_{\ell_2} \right). \quad (3.2)
\]

We stress that assumption A is responsible for the relatively simple form of the decay rates.

### 3.1 A prediction

Taking ratios of decay rates of the $\tau$, we obtain ratios of BRs. Defining

\[
x \equiv \left( \frac{M_1}{M_4} \right)^2 \quad \text{and} \quad y \equiv \left| \frac{\gamma_{\mu}}{\gamma_{e}} \right|^2,
\]

we obtain

\[
\frac{\text{BR}(\tau^- \to e^- \mu^+ \mu^-)}{\text{BR}(\tau^- \to e^- e^+ e^-)} = y \cdot \frac{4x^2 + 4}{3x^2 + 3 + 2x}, \quad (3.4a)
\]

\[
\frac{\text{BR}(\tau^- \to \mu^- \mu^+ \mu^-)}{\text{BR}(\tau^- \to e^- e^+ e^-)} = \frac{3x^2 + 3 + 2x}{4x^2 + 4}. \quad (3.4b)
\]

This implies

\[
\frac{\text{BR}(\tau^- \to e^- e^+ e^-) \cdot \text{BR}(\tau^- \to \mu^- \mu^+ \mu^-)}{\text{BR}(\tau^- \to e^- \mu^+ \mu^-) \cdot \text{BR}(\tau^- \to \mu^- e^+ e^-)} = \frac{3x^2 + 3 + 2x}{4x^2 + 4}. \quad (3.5)
\]

The maximum of the function in the right-hand side of (3.5) is 1 at $x = 1$; its minimum is $3/4$ at $x = 0$ and $x = \infty$. Therefore, we have the following prediction:

The ratio \( \frac{\text{BR}(\tau^- \to e^- e^+ e^-) \cdot \text{BR}(\tau^- \to \mu^- \mu^+ \mu^-)}{\text{BR}(\tau^- \to e^- e^+ e^-) \cdot \text{BR}(\tau^- \to \mu^- e^+ e^-)} \) should lie between \( \frac{9}{16} \) and 1.

This is a non-trivial result of our model, provided assumption A holds.

### 3.2 Suppressing $\mu^- \to e^- e^+ e^-$

With the mean lives $\tau_\mu$ and $\tau_\tau$ of muon and tau, respectively, it follows from (3.1) that

\[
R_{\text{BR}} \equiv \frac{\text{BR}(\mu^- \to e^- e^+ e^-)}{\text{BR}(\tau^- \to e^- e^+ e^-)} = \frac{\tau_\mu m_\mu}{\tau_\tau m_\tau} \quad R_X R_A = 0.45 \times 10^6 \quad (R_X R_A), \quad (3.6)
\]

where

\[
R_X \equiv \frac{X_{\mu e}}{X_{\tau e}} \quad \text{and} \quad R_A \equiv \frac{|A_{\mu e}|^2 + |A_{e \mu}|^2}{|A_{\tau e}|^2 + |A_{e \tau}|^2}. \quad (3.7)
\]

The extant experimental upper bounds on the BRs are given in table 1. In the future, it is expected that the experimental sensitivity on $\text{BR}(\mu^- \to e^- e^+ e^-)$ will reach $\sim 10^{-16}$ [5], while the sensitivity on the BRs of the four LFV $\tau$ decays may be increased by one order of
that all the Yukawa couplings are real, we read off from (3.2) the dominant terms

\[
\begin{align*}
\text{BR}(\mu^- \rightarrow e^- e^+ e^-) &< 1.0 \times 10^{-12} \\
\text{BR}(\tau^- \rightarrow e^- e^+ e^-) &< 2.7 \times 10^{-8} \\
\text{BR}(\tau^- \rightarrow e^- \mu^+ \mu^-) &< 2.7 \times 10^{-8} \\
\text{BR}(\tau^- \rightarrow \mu^- \mu^+ \mu^-) &< 2.1 \times 10^{-8} \\
\text{BR}(\tau^- \rightarrow \mu^- e^+ e^-) &< 1.8 \times 10^{-8}
\end{align*}
\]

Table 1. The experimental upper bounds on the branching ratios. The bounds are 90% CL and have been taken from [4].

magnitude to $\sim 10^{-9}$ either at a Super $B$ factory [6] or at the High Luminosity LHC [7, 8], and even reach $\sim 10^{-10}$ at Belle II [9].

We will be interested in obtaining parameter-space points for which all the BRs are below the extant experimental bounds but above the expected future sensitivities. Using the present experimental upper bound $10^{-12}$ on BR $(\mu^- \rightarrow e^- e^+ e^-)$ and taking, for definiteness, the future sensitivity on the BRs of the $\tau^-$ decays to be $10^{-9}$, we obtain from (3.6) that

\[
R_X R_A \lesssim 2 \times 10^{-9}
\]

(3.8)

for such points. This may happen either because $R_X$ is very small, or $R_A$ is very small, or both. Focussing specifically on $R_A$, by using $m_{\ell_2} \ll m_{\ell_3} \ll v$ together with the assumption that all the Yukawa couplings are real, we read off from (3.2) the dominant terms

\[
A_{\mu e} \approx \frac{v m_\mu}{\sqrt{2}} \left( \gamma_\mu^2 d_\mu \delta_\mu - \gamma_\mu^2 d_\mu \delta_\mu \right),
\]

(3.9a)

\[
A_{e\mu} \approx \frac{v m_\mu}{\sqrt{2}} \gamma_e \gamma_\mu (d_\mu \delta_\mu - d_\mu \delta_\mu).
\]

(3.9b)

Therefore, in order to obtain a small $R_A$ both $d_\mu \delta_\mu - d_\mu \delta_\mu$ and $\gamma_e^2 - \gamma_\mu^2$ should be small.

4 Numerical procedure

Solving (2.11) means finding $m_4$, $m_5$, $m_6$ and the matrix $U_R$. The latter is parameterized just as $U_L$ in (2.4), i.e. its elements are given by

\[
(U_R)_{11} = C_{12} C_{13} \exp \left[ i \left( \alpha_1^R + \beta_1^R \right) \right],
\]

(4.1a)

\[
(U_R)_{12} = S_{12} C_{13} \exp \left[ i \left( \alpha_1^R + \beta_2^R \right) \right],
\]

(4.1b)

\[
(U_R)_{13} = S_{13} \exp \left[ i \left( \alpha_1^R + \beta_3^R - \delta^R \right) \right],
\]

(4.1c)

\[
(U_R)_{21} = -S_{12} C_{23} - C_{12} S_{23} S_{13} \exp \left( i \delta^R \right) \exp \left[ i \left( \alpha_2^R + \beta_1^R \right) \right],
\]

(4.1d)

\[
(U_R)_{22} = C_{12} C_{23} - S_{12} S_{23} S_{13} \exp \left( i \delta^R \right) \exp \left[ i \left( \alpha_2^R + \beta_2^R \right) \right],
\]

(4.1e)

\[
(U_R)_{23} = S_{23} C_{13} \exp \left[ i \left( \alpha_2^R + \beta_3^R \right) \right],
\]

(4.1f)

\[
(U_R)_{31} = S_{12} S_{23} - C_{12} C_{23} S_{13} \exp \left( i \delta^R \right) \exp \left[ i \left( \alpha_3^R + \beta_1^R \right) \right],
\]

(4.1g)

\[
(U_R)_{32} = -C_{12} S_{23} - S_{12} C_{23} S_{13} \exp \left( i \delta^R \right) \exp \left[ i \left( \alpha_3^R + \beta_2^R \right) \right],
\]

(4.1h)

\[
(U_R)_{33} = C_{23} C_{13} \exp \left[ i \left( \alpha_3^R + \beta_3^R \right) \right].
\]

(4.1i)
where $S_{ij} = \sin \theta_{ij}^{R}$ and $C_{ij} = \cos \theta_{ij}^{R}$. However, following the reality assumption (2.12), the matrix in the left-hand side of (2.11) is real, hence $U_{R}$ is real as well, apart from possible imaginary factors $\epsilon_{3+j}$ in (2.13). In order to avoid finding the same solutions of (2.11) several times in different conventions, we fix the phases in $U_{R}$ as $\delta_{R}^{1}=\alpha_{R}^{1}=\alpha_{R}^{2}=\pi$ and $\alpha_{R}^{3}=\beta_{R}^{1}=\beta_{R}^{2}=\beta_{R}^{3}=0$, while simultaneously we allow the $\epsilon_{3+j}m_{3+j}$ to be either positive or negative and the angles $\theta_{ij}^{R}$ to be in any quadrant.

The left-hand side of (2.11) is determined in the following way: choosing normal mass ordering of the light neutrinos, the mass $m_{1}$ is an input and

$$m_{2} = \sqrt{m_{1}^{2} + \Delta m_{21}^{2}} \quad \text{and} \quad m_{3} = \sqrt{m_{1}^{2} + \Delta m_{31}^{2}}, \quad (4.2)$$

For the mass-squared differences and the mixing angles in $U_{\text{PMNS}}$ we take the best-fit values of [36]:

$$\Delta m_{21}^{2} = 7.39 \times 10^{-5} \text{eV}^{2}, \quad \Delta m_{31}^{2} = 2.525 \times 10^{-3} \text{eV}^{2}, \quad (4.3)$$

$$\sin^{2} \theta_{12} = 0.310, \quad \sin^{2} \theta_{13} = 0.02241, \quad \sin^{2} \theta_{23} = 0.580. \quad (4.3)$$

Our fitting program consists of two parts. In the first part, the matrix equation (2.11) is solved by using a minimization procedure wherein the function $\chi_{\text{eq}}^{2}$, given in (4.4) below, is adjusted to zero with high precision. In this part of the program all the parameters that occur in the branching ratios, except the Yukawa couplings $\gamma_{\ell}$, are determined. In the second part of the program, we use the parameters obtained in the first part and we search for $\gamma_{\ell}$ such that either several or all five branching ratios are within the future experimental reach; this is done with the help of the function $\chi_{\text{br}}^{2}$ given in (4.6) below.

The function $\chi_{\text{eq}}^{2}$ is constructed in the following way. Let $(M_{\nu}^{\text{exp}})_{ij}$ and $(M_{\nu}^{\text{theor}})_{ij}$ be the matrix elements of the matrices in the left-hand and right-hand sides, respectively, of (2.11). Then, the function that we minimize is

$$\chi_{\text{eq}}^{2} = \sum_{1 \leq i \leq j \leq 3} \left[ (f_{\text{mod}}^{ij})^{2} + (f_{\text{arg}}^{ij})^{2} \right], \quad (4.4)$$

with

$$f_{\text{mod}}^{ij} = \frac{|(M_{\nu}^{\text{exp}})_{ij}| - |(M_{\nu}^{\text{theor}})_{ij}|}{|(M_{\nu}^{\text{exp}})_{ij}| + |(M_{\nu}^{\text{theor}})_{ij}|}, \quad (4.5a)$$

$$f_{\text{arg}}^{ij} = \begin{cases} \arg (M_{\nu}^{\text{exp}})_{ij} - \arg (M_{\nu}^{\text{theor}})_{ij} & \iff \arg (M_{\nu}^{\text{exp}})_{ij} \neq 0, \\ \arg (M_{\nu}^{\text{theor}})_{ij} & \iff \arg (M_{\nu}^{\text{exp}})_{ij} = 0. \end{cases} \quad (4.5b)$$

7: This choice is arbitrary; in principle, many other phase fixings would be just as good.
8: We have not considered the case of inverted mass ordering, which is disfavoured by the phenomenological fits. We note, however, that in a recent analysis [39] the preference for normal ordering has decreased.
9: This function is appropriate for both cases of a complex or real $M_{\nu}$; in our actual practice, we only use it in the real case.
In the first part of our fitting program we proceed in the following way. The mass-squared differences $\Delta m^2_{21}$ and $\Delta m^2_{31}$ and the lepton mixing angles $\theta_{12}$, $\theta_{13}$, and $\theta_{23}$ are fixed to their best-fit values [36]. In section 2 we have already stated the values of $v$, $m_Z$, and $m_H$ used in our code. Nine parameters — the masses $M_3$ and $M_4$ of the new scalars, the mass $m_1$ of the lightest neutrino, and the real Yukawa couplings $d_\ell$ and $\delta_\ell$ for $\ell = e, \mu, \tau$ — are inputted into (2.11); that matrix equation is solved by minimizing $\chi^2_{eq}$ with respect to the six parameters $\theta_{Rij}$ and $\epsilon_{23+j}^2$, which form the output of (2.11). We consider (2.11) to be solved when $\chi^2_{eq} < 10^{-16}$; the resulting set of 15 parameters is then saved for usage in the second part of the fitting program.

Note that, since we use a minimization procedure, we may as well explore the full parameter space and minimize $\chi^2_{eq}$ with respect to all 15 parameters simultaneously. It is also possible to choose any subspace in the 15-dimensional parameter space and to perform the minimization of $\chi^2_{eq}$ in that subspace; indeed, in the following we shall do precisely this, by either fixing or imposing restrictions on the ranges of some of the input parameters prior to minimization of $\chi^2_{eq}$.

The function $\chi^2_{br}$ is constructed in the following way:

$$
\chi^2_{br} = \sum_{i=1}^{5} \left[ \Theta \left( BR_i^{\text{bound}} - BR_i^{\text{theor}} \right) \left( \frac{BR_i^{\text{bound}}}{BR_i^{\text{theor}}} \right)^2 + \Theta \left( BR_i^{\text{theor}} - BR_i^{\text{bound}} \right) \left( \frac{BR_i^{\text{theor}} - BR_i^{\text{bound}}}{k} \right)^2 \right],
$$

where the index $i$ runs over the five BRs, $\Theta$ is the Heaviside step function, $BR_i^{\text{bound}}$ denotes the experimental upper bound on each BR (these are the bounds given in table 1), $BR_i^{\text{theor}}$ is the calculated value of the BR, and $k$ is a small number that is meant to give a kick to the minimization algorithm whenever the calculated value is larger than the experimental upper bound. Note that the minimum possible value of $\chi^2_{br}$ is five, which materializes in the limit where all five calculated BRs are just a little smaller than the experimental bound on the corresponding BR.\(^{10}\) The minimization function (4.6) can handle even situations when the calculated BRs and the upper experimental bounds differ by many orders of magnitude. The function $\chi^2_{br}$ is minimized only with respect to the Yukawa couplings $\gamma_\ell$, because the other parameters have been fixed already in the first part of the fitting program. We stress that, in contrast to $\chi^2_{eq}$, it is not necessary to minimize $\chi^2_{br}$ with high precision, since our objective is to obtain BRs that are below but not necessarily close to their respective experimental bounds. We use $10^{-16}$ and $10^{-9}$ as the future experimental sensitivities on $BR(\mu^- \rightarrow e^- e^+ e^-)$ and the BRs of the $\tau^-$ decays, respectively.

\(^{10}\)One might object that by minimizing the function (4.6) one would almost always end up with points having all the computed $BR_i^{\text{theor}}$ very close to their respective present experimental upper bounds $BR_i^{\text{bound}}$. This does not happen, though, because it is quite difficult to reach the minimum value 5 of $\chi^2_{br}$ by just varying the three parameters $\gamma_{e,\mu,\tau}$. Actually, as one can check for instance by looking at figure 4 below, even after minimizing $\chi^2_{br}$ we obtain lots of points with $BR_i^{\text{theor}} \ll BR_i^{\text{bound}}$ for some of the five decays.
Often, we want to compare the results of equation (2.11) with the ones of its tree-level counterpart

\[ e^{-i\hat{a}} U_{\text{PMNS}}^* \left( \hat{m} e^{-2i\hat{b}} \right) U_{\text{PMNS}}^{\dagger} e^{-i\hat{a}} = -\frac{e^2}{2} \Delta_1 U_R^* \frac{1}{\hat{m}} U_R \Delta_1. \tag{4.7} \]

Whenever we perform such a comparison, we use the superscript "(loop)" on quantities that arise from the solution of (2.11) and the superscript "(tree)" on quantities that arise from the solution of (4.7). It is one objective of this letter to show that the quantities with superscript "(loop)" may be substantially different from the corresponding quantities with superscript "(tree)".

5 Results

5.1 Evolution of the $X_{\ell_1 \ell_2}$

In this subsection we give two examples of the way the quantities $X_{\ell_1 \ell_2}$ may change when the input parameters are varied.

In our first example we fix eight inputs as follows: $m_1 = 30 \text{ meV}$, $M_3 = 1.5 \text{ TeV}$, $M_4 = 1.6 \text{ TeV}$, $d_e = 0.01$, $d_{\mu} = 0.1$, $d_\tau = 0.001$, $\delta_e = 1$, and $\delta_\mu = 0.001$. We vary $d_\tau$ from 0.005 to 0.5 and compute $X_{\mu e}$, $X_{\tau e}$, and $X_{\tau \mu}$ for each value of $d_\tau$. In this case $\Delta_1$ is kept fixed, hence the solution of (4.7) is always the same and produces $X_{\mu e}^{(\text{tree})} = 0.000232$, $X_{\tau e}^{(\text{tree})} = 0.000328$, $X_{\tau \mu}^{(\text{tree})} = -0.000260$, and heavy-neutrino masses $m_4^{(\text{tree})} = 7.18 \times 10^8 \text{ GeV}$, $m_5^{(\text{tree})} = 9.83 \times 10^{10} \text{ GeV}$, and $m_6^{(\text{tree})} = 7.16 \times 10^{12} \text{ GeV}$. In figure 1 we display the corresponding quantities with "(loop)" superscript. In particular, one observes in the top-left panel of that figure that $X_{\mu e}^{(\text{loop})}$ is zero for $d_\tau \simeq 0.1$. In the top-right panel of figure 1 one sees that both $X_{\mu e}^{(\text{loop})}$ and $X_{\tau \mu}^{(\text{loop})}$ are one order of magnitude larger than the corresponding tree-level quantities when $d_\tau \lesssim 0.01$, and the same happens for $X_{\tau e}$ when $d_\tau \gtrsim 0.2$. In the bottom panel of figure 1 one sees that all three heavy neutrinos are heavier when their masses are computed by taking into account the loop corrections; for instance, $m_6^{(\text{loop})} \sim 10^{15} \text{ GeV}$ while $m_6^{(\text{tree})} < 10^{13} \text{ GeV}$.

In our second example we fix eight input parameters as follows: $m_1 = 30 \text{ meV}$, $M_3 = 1.5 \text{ TeV}$, $M_4 = 1.6 \text{ TeV}$, $d_e = 0.01$, $d_{\mu} = 0.1$, $\delta_e = 1$, $\delta_\mu = 0.001$, and $d_\tau = 0.1$. We vary $d_e$ from 0.005 to 0.5 and we solve both (2.11) and (4.7) for each value of $d_e$. The results obtained for the heavy-neutrino masses $m_{3+j}$ are depicted in figure 2, at the loop level in the left panel and at tree level in the right one. One sees that, in the tree-level solution, the heavy-neutrino masses exhibit a very simple behaviour: for low $d_\tau$, $m_4^{(\text{tree})}$ increases with $d_\tau$ while $m_5^{(\text{tree})}$ and $m_6^{(\text{tree})}$ remain almost constant (in reality, they also increase but very slowly); then, for intermediate $d_\tau$, it is $m_5^{(\text{tree})}$ that increases at a regular pace while $m_4^{(\text{tree})}$ and $m_6^{(\text{tree})}$ remain constant; finally, for high $d_\tau$, $m_6^{(\text{tree})}$ increases but $m_4^{(\text{tree})}$ and $m_5^{(\text{tree})}$ are stable. Including the radiative corrections (left panel of figure 2) the whole picture changes; all three heavy-neutrino masses become one or two orders of magnitude larger, and moreover $m_5^{(\text{loop})}$ and $m_6^{(\text{loop})}$ exhibit a peculiar behaviour, interchanging positions at

\(^{11}\) $M_3$ and $M_4$ must be rather close to each other, because their difference comes from a coupling in the scalar potential that is bounded by unitarity. See appendix A for details.
Figure 1. $X_{\ell_1\ell_2}^{(\text{loop})}$ (top-left panel), $X_{\ell_1\ell_2}^{(\text{loop})}/X_{\ell_1\ell_2}^{(\text{tree})}$ (top-right panel), and $m_{4,5,6}^{(\text{loop})}$ (bottom panel) against $\delta \tau$ in a case where all other input parameters are kept fixed at values given in the main text. The definition of the quantities $X_{\ell_1\ell_2}$ is given in (2.3); the definition of the right-handed neutrino masses $m_{4,5,6}$ is in (2.2); the Yukawa coupling $\delta \tau$ is defined in (2.7).

Figure 2. $m_{4,5,6}^{(\text{loop})}$ (left panel) and $m_{4,5,6}^{(\text{tree})}$ (right panel) against $d \tau$ in a case where all other input parameters are kept fixed at values given in the main text. The Yukawa coupling $d \tau$ is defined in (2.7).
$d_\tau \approx 0.04$ and then again at $d_\tau \approx 0.45$. This peculiar behaviour of $m_{5,6}^{(\text{loop})}$ has a counterpart in the behaviour of the $X_{\ell_1 \ell_2}^{(\text{loop})}$ depicted in the top-left panel of figure 3. One sees that both $X_{\mu e}^{(\text{loop})}$ and $X_{\tau e}^{(\text{loop})}$ experience sudden changes close to the point where $m_{5}^{(\text{loop})}$ and $m_{6}^{(\text{loop})}$ first interchange positions. One moreover sees that $X_{\tau e}^{(\text{loop})}$ is zero for two different values of $d_\tau$, while $X_{\mu e}^{(\text{loop})}$ is zero only once. In the bottom panel of figure 3 one sees that the $X_{\ell_1 \ell_2}^{(\text{loop})}/X_{\ell_1 \ell_2}^{(\text{tree})}$ are typically of order 10, but both $X_{\tau e}^{(\text{loop})}/X_{\tau e}^{(\text{tree})}$ and $X_{\mu e}^{(\text{loop})}/X_{\mu e}^{(\text{tree})}$ have zeros. It is amusing to note that all three $X_{\ell_1 \ell_2}^{(\text{loop})}/X_{\ell_1 \ell_2}^{(\text{tree})}$ have approximately the same value at the first point where $m_{5}^{(\text{loop})}$ and $m_{6}^{(\text{loop})}$ cross.

5.2 Scatter plots of BRs

In figure 4 we present scatter plots of the branching ratios of $^{12}\mu^{-} \to e^{-} e^{+} e^{-}$, $\tau^{-} \to e^{-} e^{+} e^{-}$, and $\tau^{-} \to \mu^{-} \mu^{+} \mu^{-}$ as functions of $m_1$. Here as elsewhere in this section we always assume, for the sake of simplicity, the neutrino mass ordering to be normal. To produce the scatter plots, we chose $m_1$ at random in between $10^{-2}$ meV to $30$ meV, prior to the minimization of $\chi_{\text{eq}}^2$; larger values of $m_1$ would violate the Planck 2018 cosmological bound on the sum of the light-neutrino masses [40]. Then the BRs are computed, as described in section 4, by consecutive minimization of $\chi_{\text{eq}}^2$ and $\chi_{\text{ls}}^2$ with respect to the remaining parameters.

---

12 As seen in (3.4), in our model the branching ratio of $\tau^{-} \to e^{-} \mu^{+} \mu^{-}$ is closely related to the one of $\tau^{-} \to e^{-} e^{+} e^{-}$, and the branching ratio of $\tau^{-} \to \mu^{-} e^{+} e^{-}$ is related to the one of $\tau^{-} \to \mu^{-} \mu^{+} \mu^{-}$. For this reason and in order to save space, we omit figures for BR \((\tau^{-} \to e^{-} \mu^{+} \mu^{-})\) and for BR \((\tau^{-} \to \mu^{-} e^{+} e^{-})\).
restrict the parameter space by adopting the boundary conditions

\begin{align}
750 \text{ GeV} &< M_{3,4} < 2 \text{ TeV}, \\
M_3^2 - \frac{8\pi}{3} v^2 &< M_4^2 < M_3^2 + \frac{8\pi}{3} v^2, \\
0.05 &\leq |d_\ell|, |\delta_\ell|, |\gamma_\ell| \leq 0.5 \quad (\ell = e, \mu, \tau),
\end{align}

and

\begin{equation}
10^{11} \text{ GeV} \leq m_{4,5,6} \leq 10^{16} \text{ GeV},
\end{equation}

with the $c_{3+j}^2 m_{3+j}$ being either positive or negative. Notice that the range of Yukawa couplings that we have considered in (5.1c) is quite restricted compared to the Yukawa couplings of the charged fermions, that are known to vary from $\sim 10^{-6}$ to $\sim 1$.

It is worth making a number of comments concerning (5.1) and (5.2):

1. The lower bound on $M_3$ and $M_4$ that we have assumed in (5.1a) agrees roughly with the results of a recent analysis \cite{41} of 2HDMs furnished with an additional $\mathbb{Z}_2$ symmetry.
Figure 5. Scatter plots of $\text{BR}^{(\text{loop})}/\text{BR}^{(\text{tree})}$ for the decays $\mu^- \to e^- e^+ e^-$ (top-left panel), $\tau^- \to e^- e^+ e^-$ (top-right panel), and $\tau^- \to \mu^- \mu^+ \mu^-$ (bottom panel). The points are the ones used in figure 4, with the same colour coding as there.

2. In (5.1b) the bounds on $M_4$ have been chosen in such a way that all the relevant conditions on the 2HDM scalar potential are met. Namely, the difference between $M_3^2$ and $M_4^2$ originates in a coupling of the scalar potential that is bounded by unitarity, and therefore $|M_3^2 - M_4^2|$ cannot be too large. See appendix A for details.

3. Sometimes the solution of (2.11) requires one of the $m_{3+j}$ to be very large, even divergent. This is not surprising because, when e.g. $m_6 \to \infty$, the contribution of $m_6$ to (2.11) simply vanishes. Unfortunately, though, when $m_6 \to \infty$ the $X_{\ell_1 \ell_2}$ diverge. We avoid this problem by discarding, through the upper bound in (5.2), those points where the solution of (2.11) requires very large $m_{3+j}$.

4. We have obtained points with values of the heavy-neutrino masses as low as $10^9$ GeV. However, those points have very low BRs for the decays of the $\tau^-$, of order $10^{-12}$. In (5.2) we have discarded those points by enforcing a lower bound on the heavy-neutrino masses.

In figure 5 we display the ratios $\text{BR}^{(\text{loop})}/\text{BR}^{(\text{tree})}$ for the same points as in figure 4 and with the same colour notation. One sees that for the $\tau^-$ decays the BRs derived from (2.11) may easily be one or two orders of magnitude either above or below the corresponding BRs derived from (4.7). For the decay $\mu^- \to e^- e^+ e^-$ things may be much more dramatic, with differences of several orders of magnitude; this happens because either $X_{\mu e}^{(\text{loop})}$ or
Figure 6. Scatter plots of $R_A$ vs. $R_X$ (left panel) and of their product $R_X R_A$ vs. $R_{BR}$ (right panel) for the blue points of figure 4. The definitions of $R_A$, $R_X$, and $R_{BR}$ are given in (3.6) and (3.7).

$X_{\mu e}^{(\text{tree})}$ frequently become zero. It is worth mentioning that by allowing for wider ranges of the Yukawa couplings (for example, allowing $|d_\ell|$, $|\delta_\ell|$, and $|\gamma_\ell|$ to be between 0.001 and 1) would lead to the ratios $BR^{(\text{loop})}/BR^{(\text{tree})}$ being sometimes much larger; those ratios could be two orders of magnitude larger or smaller than is shown in figure 5.

5.3 The suppression of $\mu^- \rightarrow e^- e^+ e^-$

In figure 6 we reuse the blue points of the previous figures 4 and 5, viz. points for which all five BRs are in between the respective present upper bounds and future expected sensitivities. For those points, we display $R_{BR}$ defined in (3.6), and $R_X$ and $R_A$ defined in (3.7). In the right panel one sees that the inequality (3.8) holds and that $R_X$ is proportional to $R_{BR}$ as stated in (3.6). In the left panel one sees that the smallness of $R_X R_A$ most of the time occurs because both $R_A$ and $R_X$ are small, but there is a non-negligible fraction of points where one of them is extremely small and the other one is not small.

The discussion at the end of section 3.2 suggests that the smallness of $R_A$ is correlated with the smallness of the asymmetries

$$A_1 \equiv \frac{d_e \delta_\mu - d_\mu \delta_e}{d_e \delta_\mu + d_\mu \delta_e} \quad \text{and} \quad A_2 \equiv \frac{\gamma_\mu^2 - \gamma_e^2}{\gamma_\mu^2 + \gamma_e^2}. \quad (5.3)$$

Using the same points as in figure 6, these asymmetries are displayed in figure 7. One sees that $A_1$ and $A_2$ are indeed very small when $R_A \lesssim 10^{-7}$, but they may be largish for $R_A$ above that value; we remind the reader that, like we saw in figure 6, the smallness of $R_X R_A$ is often due to the smallness of $R_X$ and not to the smallness of $R_A$, or vice-versa.

5.4 Benchmark points

In table 2 we produce three benchmark points. The first nine lines of that table contain the input to (2.11), viz. the matrices $\Delta_1$ and $\Delta_2$, the lightest-neutrino mass $m_1$, and the new-scalar masses $M_3$ and $M_4$. In the next six lines of table 2 one sees the output of (2.11), viz. the heavy-neutrino masses $c_{3+}^2 m_{3+}$ and the angles $\theta_{ij}^R$ that parameterize the matrix $U_R$. In the next three lines of table 2 one finds the parameters $\gamma_\ell$ that we have fitted in order to obtain the desirable branching ratios which are in the ensuing five lines of the table.
Finally, in the last three lines of table 2 we compare the values of the quantities $X_{\ell_1\ell_2}^{(\text{loop})}$ that were obtained from the solution of the one-loop equation (2.11) to the quantities $X_{\ell_1\ell_2}^{(\text{tree})}$ that result from the solution to the tree-level equation (4.7).

All the points in table 2 have small $A_2$ asymmetries. The asymmetry $A_1$ is also small for point 1, but not for points 2 and 3; the latter points rely on very small $X_{\mu e}$ to suppress $\text{BR}(\mu^- \rightarrow e^- e^+ e^-)$.

6 Conclusions

The predictions for the lepton-flavour-violating charged-lepton decays may be used to discriminate among theoretical models. For instance, it has been found [43] that, in a model with a heavy charged gauge boson, the present bounds on $\mu^- \rightarrow e^- \gamma$ and $\mu^- \rightarrow e^- e^+ e^-$ restrict the parameters of the model in such a way that the decays $\tau^- \rightarrow \ell_2^+ \ell_3^- \ell_3^-$ ($\ell_2, \ell_3 = e, \mu$) will be invisible in the foreseeable future. In this letter we have considered a model with radically different predictions. In our model, LFV decays like $\mu^- \rightarrow e^- \gamma$ and $Z \rightarrow e^+ e^-$ are invisible, while $\mu^- \rightarrow e^- e^+ e^-$ and $\tau^- \rightarrow \ell_2^+ \ell_3^- \ell_3^-$ might be observed in future experiments.

Here we have investigated the one-loop radiative corrections to the light-neutrino mass matrix and their impact on the branching ratios $\text{BR}(\ell_1^- \rightarrow \ell_2^- \ell_3^- \ell_3^-)$. That impact occurs because the radiative corrections strongly influence the evaluation of the heavy-neutrino masses $m_{4,5,6}$ and of the mixing matrix $U_R$ of the heavy neutrinos. In our model $\text{BR}(\ell_1^- \rightarrow \ell_2^- \ell_3^- \ell_3^-)$ is proportional to $|X_{\ell_1\ell_2}|^2$, where the quantities $X_{\ell_1\ell_2}$ defined in (2.3) depend on $m_{4,5,6}$ and $U_R$.

We have shown that the one-loop radiative corrections to the light-neutrino mass matrix may modify that matrix so much that the model’s predictions for $\mu^- \rightarrow e^- e^+ e^-$ and $\tau^- \rightarrow \ell_2^+ \ell_3^- \ell_3^-$ change drastically. This is especially true for $\text{BR}(\mu^- \rightarrow e^- e^+ e^-)$, which may shift by several orders of magnitude when one (dis)considers the effect of the radiative corrections on the determination of the heavy-neutrino masses and mixings. This happens, in particular, because $X_{\mu e}$ may be zero for different values of the model’s parameters at the tree level and at the one-loop level. The predictions for the four decays $\tau^- \rightarrow \ell_2^+ \ell_3^- \ell_3^-$...

Table 2. Three benchmark points.

usually change by no more than two orders of magnitude when one takes into account the radiative corrections, but for values of the Yukawa couplings larger than the ones displayed in figure 4 and given in (5.1c), the effects on $\text{BR} \left( \tau^- \rightarrow \ell_2^+ \ell_3^- \ell_3^- \right)$ may be dramatic too.

Our work highlights the necessity of taking into account the one-loop radiative corrections to the light-neutrino mass matrix when making any numerical assessment or prediction of an effect that involves the masses $m_{4,5,6}$ and the mixing matrix $U_R$. Usage of the standard seesaw formula (2.6) is not adequate when one looks for detailed numerical predictions because the ‘scotogenic-type’ contributions to $\delta M_L$ in (2.10c) and (2.10d) may
be non-negligible or even dominant. This happens even when one takes into account the restrictions posed by unitarity of the scalar potential on the squared-mass differences among the neutral scalars; though those differences are rather small, the effects of the radiative corrections are nevertheless large in general.

A The maximum possible value of $|M_3^2 - M_4^2|$

In this appendix we study in detail the scalar potential of the 2HDM with alignment. Our purpose is to demonstrate that the difference between the squared masses of the two new neutral scalars of that model may reach $v^2 (8\pi/3) \approx 5.07 \times 10^5 \text{GeV}^2$. We do not claim this to be an absolute upper bound; simply, we were able to demonstrate analytically that it may be reached. On the other hand, numerical scans that two of us have performed [42] suggest that $8\pi/3$ is indeed the maximum possible value of the parameter $\lambda_5$ of the scalar potential, even in the general case without alignment.

A.1 The scalar potential of the 2HDM

Let the two doublets be $\Phi_1 = (\varphi_1^+ , \varphi_1^0)^T$ and $\Phi_2 = (\varphi_2^+ , \varphi_2^0)^T$. The scalar potential is [17]

$$V = \mu_1 \Phi_1^\dagger \Phi_1 + \mu_2 \Phi_2^\dagger \Phi_2 + (\mu_3 \Phi_1^\dagger \Phi_2 + H.c.)$$

$$+ \frac{\lambda_1}{2} (\Phi_1^\dagger \Phi_1)^2 + \frac{\lambda_2}{2} (\Phi_2^\dagger \Phi_2)^2 + \lambda_3 \Phi_1^\dagger \Phi_1 \Phi_2^\dagger \Phi_2 + \lambda_4 \Phi_1^\dagger \Phi_2 \Phi_2^\dagger \Phi_1$$

$$+ \left[ \frac{\lambda_5}{2} (\Phi_1^\dagger \Phi_2)^2 + (\lambda_6 \Phi_1^\dagger \Phi_1 + \lambda_7 \Phi_2^\dagger \Phi_2) \Phi_1^\dagger \Phi_2 + H.c. \right],$$

where $\mu_1,2$ and $\lambda_{1,\ldots,4}$ are real while $\mu_3$ and $\lambda_{5,\ldots,7}$ are in general complex. It is convenient to define

$$\lambda_{\pm} := \frac{\lambda_1 \pm \lambda_2}{2} \quad \text{and} \quad \bar{\lambda}_{\pm} := \lambda_6 \pm \lambda_7. \quad \text{(A.2)}$$

The coefficients $\lambda_{1,\ldots,7}$ are subject to two types of conditions: the unitarity conditions and the boundedness-from-below (BFB) conditions.
A.2 Unitarity conditions

We consider three matrices:

\[ M_1 = \begin{pmatrix}
\lambda_+ + \lambda_4 & \text{Re} \tilde{\lambda}_+ & -\text{Im} \tilde{\lambda}_+ & \lambda_-
\text{Re} \tilde{\lambda}_+ & \lambda_3 + \text{Re} \lambda_5 & -\text{Im} \lambda_5 & \text{Re} \tilde{\lambda}_-
n-\text{Im} \tilde{\lambda}_+ & -\text{Im} \lambda_5 & \lambda_3 - \text{Re} \lambda_5 & -\text{Im} \lambda_-
\lambda_- & \text{Re} \tilde{\lambda}_- & -\text{Im} \lambda_- & \lambda_+ - \lambda_4
\end{pmatrix}, \quad (A.3a) \]

\[ M_2 = \begin{pmatrix}
3\lambda_+ + 2\lambda_3 + \lambda_4 & 3\text{Re} \tilde{\lambda}_+ & -3\text{Im} \tilde{\lambda}_+ & 3\lambda_-
3\text{Re} \tilde{\lambda}_+ & \lambda_3 + 2\lambda_4 + 3\text{Re} \lambda_5 & -3\text{Im} \lambda_5 & 3\text{Re} \tilde{\lambda}_-
n-3\text{Im} \tilde{\lambda}_+ & -3\text{Im} \lambda_5 & \lambda_3 + 2\lambda_4 - 3\text{Re} \lambda_5 & -3\text{Im} \tilde{\lambda}_-
3\lambda_- & 3\text{Re} \tilde{\lambda}_- & -3\text{Im} \lambda_- & 3\lambda_+ - 2\lambda_3 - \lambda_4
\end{pmatrix}, \quad (A.3b) \]

\[ M_3 = \begin{pmatrix}
\lambda_1 & \lambda_5 & \sqrt{2} \lambda_6 \\
\lambda_5^* & \lambda_2 & \sqrt{2} \lambda_7^* \\
\sqrt{2} \lambda_6^* & \sqrt{2} \lambda_7^* & \lambda_3 + \lambda_4
\end{pmatrix}. \quad (A.3c) \]

The unitarity conditions are the following [44–46]: the moduli of the eigenvalues of \( M_1, M_2, \) and \( M_3, \) and also \(|\lambda_3 - \lambda_4|\), must be smaller than \( 8\pi \). 

A.3 BFB conditions

We consider the matrix

\[ \Lambda_E = \begin{pmatrix}
\lambda_+ + \lambda_3 & \text{Re} \tilde{\lambda}_+ & -\text{Im} \tilde{\lambda}_+ & \lambda_-
-\text{Re} \tilde{\lambda}_+ & -\lambda_4 - \text{Re} \lambda_5 & \text{Im} \lambda_5 & -\text{Re} \tilde{\lambda}_-
n\text{Im} \tilde{\lambda}_+ & \text{Im} \lambda_5 & -\lambda_4 + \text{Re} \lambda_5 & \text{Im} \tilde{\lambda}_-
-\lambda_- & -\text{Re} \tilde{\lambda}_- & \text{Im} \lambda_- & -\lambda_+ + \lambda_3
\end{pmatrix}. \quad (A.4) \]

Let \( \Lambda_0, \Lambda_1, \Lambda_2, \) and \( \Lambda_3 \) be the eigenvalues of \( \Lambda_E \). The BFB conditions are the following [47–51]:

1. \( \Lambda_0, \Lambda_1, \Lambda_2, \) and \( \Lambda_3 \) are real.
2. The largest eigenvalue, say \( \Lambda_0 \), is positive.
3. The (1, 1) matrix element of the \( 4 \times 4 \) matrix

\[ (\Lambda_E - \Lambda_1 \times \mathbb{I}_{4 \times 4}) \times (\Lambda_E - \Lambda_2 \times \mathbb{I}_{4 \times 4}) \times (\Lambda_E - \Lambda_3 \times \mathbb{I}_{4 \times 4}) \quad (A.5) \]

is positive.

A.4 The Higgs basis and the alignment limit

Let \( v = 246\text{ GeV} \) be the vacuum expectation value (VEV). We use the Higgs basis and write \( \Phi_{1,2} \) as in (1.4). In order that the doublet \( \Phi_2 \) has no VEV, the parameter \( \mu_3 \) must be equal to \(-\lambda_6 v^2/2 \) [52]. Moreover, \( \mu_1 = -\lambda_1 v^2/2 \) so that \( v \) is the correct value of the VEV [52].
The mass terms of $H^+, H$, $S^0_3$, and $S^0_4$ are given by

$$V = \cdots + m^2_C H^+ H^- + \frac{1}{2} \left( H, S^0_3, S^0_4 \right) M \left( \begin{array}{c} H \\ S^0_3 \\ S^0_4 \end{array} \right),$$

(A.6)

where $m^2_C = \mu_2 + v^2\lambda_3/2$ is the squared mass of the physical charged scalar and [52]

$$M = \begin{pmatrix} v^2\lambda_1 - v^2\text{Re} \tilde{\lambda}_6 & v^2\text{Re} \tilde{\lambda}_6 & -v^2\text{Im} \tilde{\lambda}_6 \\ v^2\text{Re} \tilde{\lambda}_6 & m^2_C + v^2 \left( \lambda_4 + \text{Re} \tilde{\lambda}_5 \right)/2 & -v^2\text{Im} \tilde{\lambda}_5/2 \\ -v^2\text{Im} \tilde{\lambda}_6 & -v^2\text{Im} \tilde{\lambda}_5/2 & m^2_C + v^2 \left( \lambda_4 - \text{Re} \tilde{\lambda}_5 \right)/2 \end{pmatrix},$$

(A.7)

where $\tilde{\lambda}_5 := e^{-2i\alpha}\lambda_5$ and $\tilde{\lambda}_6 := e^{-i\alpha}\lambda_6$.

We now assume alignment, which means that $H$ has mass $m_H = 125$ GeV and does not mix with $S^0_3$ and $S^0_4$. Clearly, from (A.7), the absence of mixing means $\lambda_6 = 0$, while $m^2_H = v^2\lambda_1$, hence

$$\lambda_1 = \left( \frac{125}{246} \right)^2 \approx 0.258.$$  

(A.8)

Alignment can be enforced through a $\mathbb{Z}_2$ symmetry $\Phi_2 \rightarrow -\Phi_2$ in the so-called inert 2HDM [47, 53–55]. However, that possibility is not suitable for our purposes, because we need all the Yukawa couplings in (1.2) to be nonzero. Therefore, in this letter alignment is just an ad hoc assumption. We choose the phase $\alpha$ to offset $\text{arg} \lambda_5$, viz. we choose $e^{-2i\alpha}\lambda_5 = \pm |\lambda_5|$. Then, from (A.7) the squared masses of $S^0_3$ and $S^0_4$ are

$$M^2_3 = m^2_C + v^2 \left( \lambda_4 \mp |\lambda_5| \right)/2 \quad \text{and} \quad M^2_4 = m^2_C + v^2 \left( \lambda_4 \mp |\lambda_5| \right)/2,$$

(A.9)

respectively. Their difference is given by $|M^2_3 - M^2_4| = v^2|\lambda_5|$, just as in the scotogenic model [35]. Thus, finding the maximum possible value of $|M^2_3 - M^2_4|$ is equivalent to finding the maximum possible value of $|\lambda_5|$, which is determined by the unitarity and BFB conditions.

### A.5 Additional conditions

One must guarantee that our assumed vacuum state is indeed the state with the lowest value of $V$, viz. that we are not in the situation where there are two local minima of the potential and we are sitting on the local minimum with the highest value of $V$ instead of being at the true vacuum; this undesirable situation has been called ‘panic vacuum’. This produces the following condition [49–51, 56]. Let $\zeta \equiv 2m^2_C/v^2$ and let us order the eigenvalues of $\Lambda_E$ as $\Lambda_0 > \Lambda_1 > \Lambda_2 > \Lambda_3$. Then, either $\zeta > \Lambda_1$ or $\Lambda_2 > \zeta > \Lambda_3$.

There is also a phenomenological condition arising from the oblique parameter $T$. With alignment [31],

$$T = \frac{1}{16\pi s^2_W m^2_W} \left[ f \left( m^2_C, M^2_3 \right) + f \left( m^2_C, M^2_4 \right) - f \left( M^2_3, M^2_4 \right) \right],$$

(A.10)
where \( s_w^2 = 0.22 \) is the squared sine of the weak mixing angle, \( m_W = 80.4 \text{ GeV} \) is the mass of the \( W^\pm \) gauge bosons, and

\[
f(a, b) = \begin{cases} \frac{a + b}{2} - \frac{ab}{a - b} \ln \frac{a}{b} & \iff a \neq b, \\ 0 & \iff a = b. \end{cases}
\]

(A.11)

The phenomenological constraint is \( T = 0.03 \pm 0.12 \) [4].

**A.6 The special case \( \lambda_1 = \lambda_2, \ \lambda_6 = \lambda_7 = 0 \)**

When \( \lambda_6 = \lambda_7 = 0 \), i.e. \( \bar{\lambda}_+ = \bar{\lambda}_- = 0 \), the matrices \( M_{1,2,3} \) and \( \Lambda_E \) decompose as \( 2 \times 2 \) matrices, their eigenvalues are easy to compute, and the unitarity and BFB conditions become much simpler [17]. With the additional condition \( \lambda_1 = \lambda_2 \), they are

\[
\begin{align*}
|\lambda_3 \pm \lambda_4| &< 8\pi, \\
|\lambda_3 \pm |\lambda_5|| &< 8\pi, \\
|\lambda_3 + 2\lambda_4 \pm 3|\lambda_5|| &< 8\pi, \\
|\lambda_1 \pm |\lambda_5|| &< 8\pi, \\
|\lambda_1 \pm \lambda_4| &< 8\pi, \\
|2\lambda_3 + \lambda_4 \pm 3\lambda_1| &< 8\pi, \\
\lambda_1 &> 0, \\
\lambda_3 &> -\lambda_1, \\
|\lambda_5| &< \lambda_1 + \lambda_3 + \lambda_4. \tag{A.12} \\
\end{align*}
\]

(A.12)

Notice that in this case

\[
\Lambda_0 = \lambda_3 + \lambda_1 \tag{A.13}
\]

while \( \Lambda_1, \Lambda_2, \) and \( \Lambda_3 \) are some permutation of

\[
\lambda_3 - \lambda_1, \ -\lambda_4 + |\lambda_5|, \ \text{and} \ -\lambda_4 - |\lambda_5|. \tag{A.14}
\]

**A.7 A solution**

With \( \lambda_1 \) given by (A.8), there is a solution to (A.12):

\[
\lambda_3 = \frac{16\pi}{3} - 2\lambda_1 - \epsilon, \quad \lambda_4 = -\frac{8\pi}{3} + \lambda_1 + \epsilon, \quad |\lambda_5| = \frac{8\pi}{3} - \epsilon, \tag{A.15}
\]

where

\[
0 < \epsilon < \frac{8\pi}{3}. \tag{A.16}
\]

With this solution we learn that \( |\lambda_5| \) may be as high as 8.377, and therefore \( |M_3^2 - M_4^2| \lesssim 5.07 \times 10^5 \text{ GeV}^2 \). For instance, with \( (M_3 + M_4)/2 = 1 \text{ TeV} \) one has \( |M_3 - M_4| \lesssim 253 \text{ GeV} \).

With (A.15),

\[
\{ M_3^2, \ M_4^2 \} = \left\{ m_C^2 + v^2 \frac{\lambda_1}{2}, \ m_C^2 + v^2 \left( -\frac{8\pi}{3} + \frac{\lambda_1}{2} + \epsilon \right) \right\}. \tag{A.17}
\]

- 23 -
We are interested in the situation where $\epsilon$ is rather small, so that $|\lambda_5|$ is not very far from $8\pi/3$. When $\epsilon$ is small, $m_C^2$ lies in between the $M_3^2$ and $M_4^2$ given in (A.17), but it is very close to one of them because $\lambda_1$ is so small. Then, $T$ is negative but very small, automatically satisfying the phenomenological constraint on that parameter.

With (A.15) one has
\begin{equation}
\{\Lambda_1, \Lambda_2\} = \left\{ \frac{16\pi}{3} - 3\lambda_1 - \epsilon, \frac{16\pi}{3} - \lambda_1 - 2\epsilon \right\}.
\end{equation}

Therefore, if we choose
\begin{equation}
m_C^2 \geq v^2 \left( \frac{8\pi}{3} - \frac{\lambda_1}{2} \right),
\end{equation}
we avoid the undesirable situation of panic vacuum. Thus, we must have $m_C \gtrsim 707$ GeV. This lower bound on $m_C$ coincides with an analogous bound obtained in a recent phenomenological analysis [41].

Our solution (A.15) explicitly demonstrates that $|M_3^2 - M_4^2|$ may reach $v^2 (8\pi/3)$ without violating the unitarity and BFB conditions and with a very small oblique parameter $T$. Moreover, the inequality (A.19) provides a way to choose the mass of the physical charged scalar such as to evade panic vacuum.
