1 | INTRODUCTION

Recent progress and advancement in information and communication technology (ICT) has allowed for nationwide data to be centralized in a data center, allowing us to use large databases for various purposes. Within health care, use of a clinical registry to collect national data into a large database and analyze it can lead to significant improvements in health-care quality. A nationwide multicenter registry exceeds the abilities of a small or single institution registry and allows for the collection of information necessary to contribute to improving health-care quality on a national level.

The National Clinical Database (NCD) in Japan and the American College of Surgeons (ACS) National Surgical Quality Improvement Program (NSQIP) based in the USA were both established to serve as nationwide clinical registries for research. We have carried out a joint project, the 30-day Mortality Risk Model Study and, currently, we are working on several joint projects such as the Morbidity-Mortality Study, Japan-USA Calibration Study, Geriatric Study, and Safety Culture Study as well as Auditing in JSGS/NCD with reference to the NSQIP method. These joint projects will continue to provide us with important information and data to drive improvements in surgical care in both countries. This will also help us to identify any unknown weaknesses in the health-care systems of the USA and Japan.

KEYWORDS
big data, gastroenterological surgery, surgical outcome

Abstract
The Japanese Society of Gastroenterological Surgery (JSGS) and the American College of Surgeons National Surgical Quality Improvement Program (ACS-NSQIP) have collaboratively developed several clinical projects since 2011 using two nationwide clinical registries with the goal of achieving further improvement of surgical quality in both countries. In this review, the historical viewpoints and the collaboration between JSGS and ACS and their use of nationwide registries [National Clinical Database (NCD) and NSQIP] for research are reviewed. We have carried out a joint project, the 30-day Mortality Risk Model Study and, currently, we are working on several joint projects such as the Morbidity-Mortality Study, Japan-USA Calibration Study, Geriatric Study, and Safety Culture Study as well as Auditing in JSGS/NCD with reference to the NSQIP method. These joint projects will continue to provide us with important information and data to drive improvements in surgical care in both countries. This will also help us to identify any unknown weaknesses in the health-care systems of the USA and Japan.
surgery. Collaboration between the two countries has been established to support efforts within each country to improve surgical care. In this review, collaboration between the Japanese Society of Gastroenterological Surgery (JSGS) and ACS is described, and their use of nationwide registries (NCD and NSQIP) for research is reviewed by summarizing successful past collaborative studies as well as ongoing projects to improve surgical care.

2 | ESTABLISHMENT AND DEVELOPMENT OF ACS-NSQIP

National Surgical Quality Improvement Program was first established in 1994 in 132 Veterans Affairs (VA) hospitals following the success of the National VA Surgical Risk study (Table 1). The National VA Surgical Risk study developed and successfully implemented a system for the prospective collection of postoperative outcomes and assessment of risk-adjusted hospital performance. This has grown to include more than 700 hospitals participating in NSQIP in 2018, and it continues to grow and expand (Table 2). ACS has developed NSQIP and other quality improvement programs following the same model, which comprise four important processes: (i) establish standards; (ii) build infrastructure to support the standards; (iii) develop databases to measure performance against those standards; and (iv) provide external peer-reviewed verification.6

The next development for ACS is to complete the ACS Data Platform Project, which aims to combine multiple ACS clinical registries including NSQIP, NSQIP-peds, National Cancer Database (NCDB), Trauma Quality Improvement Program (TQIP), Metabolic and Bariatric Surgery Accreditation and Quality Improvement Program (MBSAQIP), and Surgeon Specific Registry (SSR) into one integrated platform.

3 | ESTABLISHMENT AND DEVELOPMENT OF NCD

No nationwide clinical data on surgical outcomes existed in Japan until JSGS formed a database committee in order to establish a nationwide surgical registry linked to the board certification system in 2006 (Table 1). NCD was established with support of the Japan Surgical Society (JSS) and JSGS and partially with support of a grant from the Ministry of Health, Labour and Welfare in 2010. The purpose of NCD was to systematically gather clinical information, analyze these data for quality improvement, follow the best medical practices, and maintain a high standard of care for all people in Japan. Prior to the establishment of NCD, the Japan Cardiovascular Surgery Database (JACVSD) was launched in 2000 to develop a nationwide database on cardiovascular surgery,7 which served as a large influence for the development of NCD. At that time, NSQIP was already established and operating, and the development of NCD was influenced by the surgical registry already established by NSQIP. In order to promote the ability for future collaboration between the USA and Japan, the NCD implemented the variables already being abstracted within NSQIP.2

National Clinical Database is now recognized as a fundamental registry linked to the board certification system in JSS and JSGS since 2016. Data registration is also one of the requirements for insurance coverage of new surgical techniques, such as laparoscopic advanced hepatobiliary pancreatic (HBP) surgery or robotics surgeries, which started in 2018. There are currently over 5000 institutions participating in the NCD and over 1.2 million cases per year have been registered between 2011 and 2017. NCD also began to gather additional information outside of the variables captured in NSQIP, including in-hospital death, tumor node metastasis (TNM) classification for cancer, and other postoperative morbidities. Organ-specific cancer registries have been established since 1952, but they were separately managed until recently where many of them were brought together on the same platform using the NCD system.8 This includes breast cancer registration of the Japanese Breast Cancer Society (2012-), the Japan Pancreatic Cancer Registry (2012-), and liver cancer registry by the Liver Cancer Study Group of Japan (2015-) that were all integrated onto the same platform of web-based registration system of the NCD. Other cancer registries such as the Japanese Lung Cancer Registry are now preparing to use the NCD system.

4 | RELATIONSHIP OF ACS AND JSGS: FORMATION OF NCD WITH SUPPORT OF NSQIP

Collaboration between ACS and JSGS began when members of JSGS visited ACS in 2010 (H.M., M.G.) to learn about the NSQIP system in preparation for the creation of the national clinical registry for

gastroenterological surgery. NCD was started using a three-level platform for surgical registry (Figure 1). The first level includes fundamental data (date of birth, gender, procedure code, date of surgery, operator/assistants, simultaneous surgery, involvement of anesthesiologist, postoperative diagnosis, emergency/elective) from all surgical cases. The second level includes detailed information for the board certification system of the JSGS. Moreover, additional detailed data are entered for eight major gastrointestinal procedures (esophagectomy, total and distal gastrectomy, right hemicolectomy, low anterior resection, hepatectomy, pancreaticoduodenectomy, and surgery for acute diffuse peritonitis), in which the data that are abstracted align with the NSQIP variables. Finally, the third level consists of more specific variables for advanced surgery, such as for hepatobiliary (HPB) surgery. In 2011, the JSGS and ACS collaboration was solidified and collaborative projects began using NCD and NSQIP with the unified goal of improving surgical quality in both countries. This successful collaboration was maintained with annual meetings and web conferences.

5 | COLLABORATIVE STUDIES BETWEEN USA AND JAPAN

There are various aspects of health care between the USA and Japan that differ greatly between the two countries. There are system-based differences such as insurance coverage, cost of treatment, and hospital volume, as well as patient population differences such as average age and body mass index (BMI). Nevertheless, it is still possible to compare the outcomes as the same variables are used in gathering clinical data for each clinical registry and can be accounted for when creating models.

5.1 | Thirty-day Mortality Risk Model Study

The first collaborative study between NCD and NSQIP was a comparison of the risk models created for postoperative 30-day mortality in major gastroenterological surgery. Risk calculators were created from both NCD and NSQIP individually, modeling 30-day mortality in right hemicolectomy (RH), low anterior resection (LAR), and pancreaticoduodenectomy (PD). These calculators provided risk-adjusted estimations for mortality in each case, which is essential for understanding factors leading to 30-day mortality from each country.

This study involved two steps to accurately evaluate the predictive value of each risk calculator. The first step set out to establish the model, using the same predictive variables from NCD and NSQIP data to develop risk models for each procedure (RH, LAR, and PD). The second step involved determining the applicability of one country’s model to the other country by exchanging the risk calculators developed using NCD and NSQIP and applying them to the other data set (NCD calculator in NSQIP dataset and vice versa). We found significant differences in the patient populations captured by NCD and NSQIP, especially in age, BMI class, and chronic kidney disease (CKD). Patients in Japan were older, had lower BMI, and had higher stages of renal dysfunction when compared to patients in the USA. There were also differences in length of hospital stay (LOS) with LOS being shorter in the USA in all three procedures studied (procedure, mean (IQR): RH 5 (4-7) vs
Odds ratios for each of the risk factors in the NCD and NSQIP models were compared and appeared to be similar; however, further analysis with a Hosmer-Lemeshow test demonstrated that the risk calculators created in Japan were not accurate in predicting mortality using the NSQIP data and the risk calculators created in the USA were not accurate in predicting mortality using the NCD data, thus demonstrating that local risk models were not accurate in predicting mortality using data from other countries. This was the first study that showed the feasibility and utility of international collaboration using nationwide clinical registries, but showed that local risk models remain important at this time.

5.2 | Morbidity-Mortality Study

Based on the results of the 30-day Mortality Risk Model Study, future research is being directed towards studying the differences in patient demographics between the two countries, especially the differences in preoperative comorbidities and their association with postoperative outcomes. A current ongoing project includes comparing preoperative comorbidities between NCD and NSQIP and their association with differences in postoperative outcomes such as 30-day mortality and morbidities in major gastroenterological surgeries (RH, LAR, hepatectomy and PD; Figure 2). We are now summarizing the results and interpretation of them.

5.3 | Japan-USA Calibration Study

Another ongoing project within the JSGS and ACS collaboration involves validating a global model of the NSQIP risk calculator. NSQIP recently launched a universal risk calculator using a global model, in which all current procedural terminology (CPT) codes are included.16 We are planning to conduct a large-scale validation study using the NSQIP risk calculator on NCD data, which will provide insight into the differences in expectations and outcomes between the USA and Japan. As we would have a very large sample from nearly all Japanese hospitals, this would be a country-wide validation exercise. Analyses are being scheduled between NCD and NSQIP.

5.4 | Geriatric Study

Surgery for the geriatric population is rapidly growing in both countries. In Japan, it is projected that people aged over 65 years will make up 33.3% of the population by 2036.17 The age distribution...
of patients who undergo major gastrointestinal surgery is also changing rapidly. From 2011 to 2016, the rate of octogenarian or older individuals receiving surgery increased by as little as 4.3% in those undergoing LAR to 27.6% in those undergoing major hepatectomy. Given these data, it was important to conduct further research into the field of geriatric surgery using prospectively collected national data, which had not been previously done in Japan. The geriatric pilot study at the ACS began in 2015 with 24 hospitals enrolled, and data of more than 20,000 cases collected. NSQIP and a panel of experts in geriatrics established a set of standards for geriatric surgery and developed these standards into data variables for collection into the pilot study at participating hospitals. Additionally, a verification process was established that involved site visits to participating hospitals to check that these geriatric standards have been upheld. So far, several studies have been carried out and published in a geriatric pilot study in NSQIP. Similarly, the JSGS geriatric pilot prospective study was started with support from a Health and Labour Sciences Research Grant, and will gather data from 22 academic and community hospitals in 2018, and will be using similar variables to the geriatric pilot in NSQIP (Table 3). Data analyses and comparison between Japan and the USA will be conducted in 2019.

5.5 Safety Culture Study

Patient safety culture is one of the key factors for quality improvement in surgery and within a healthcare system. A study by Sheetz et al. showed that hospital safety characteristics influenced the rate of failure to rescue following major surgery. The Agency for Healthcare Research and Quality (AHRQ) released the Hospital Survey on Patient Safety Culture for providers and other staff to assess the patient safety culture in their hospitals. Since

then, hundreds of hospitals across the USA and internationally have implemented the survey. In Japan, hospital safety culture has not been assessed or provided to healthcare workers in the field of surgery.

If other, please specify:

33 How frequently does your division conduct a morbidity & mortality conference?

| Weekly | Yes |
| Less than weekly, more than monthly | No |

(Continues)
Through the ongoing collaboration between JSGS and ACS, another ongoing collaborative project involves comparison of safety culture and its impact on surgical outcomes. The safety culture survey questionnaires used by the ACS were translated into Japanese and turned into a web-based survey that was sent to 2972 institutions and hospitals and answered by 1696 hospitals (57.1%) in 2016. The list of questions in the survey is provided in Table 4, and these data will be interpreted and analyzed in our ongoing collaboration.

### 5.6 Audit for data verification

National Clinical Database and NSQIP are both web-based clinical registries that are very similar in many aspects. In both NCD and NSQIP, data are entered online in a Health Insurance Portability and Accountability Act (HIPAA)-compliant, secure, web-based platform that can be accessed 24 hours a day. Blinded, risk-adjusted information is then shared with all hospitals, allowing them to nationally benchmark their complication rates and surgical outcomes. NSQIP provides auditing to ensure data reliability and, in the NCD, only the first level of clinical data was initially targeted for auditing in the field of gastroenterological surgery. Audits for second-level clinical data in NCD were then implemented in 2015 for 2014 data, following the same strategy used by NSQIP, where NCD selects 5% of participating institutions with JSGS accreditation (from n = 853) and checks 45 items including 27 items for evaluation of discrepancy. A rate of <5% discrepancy is accepted, and audit results were provided to each institution. In 2015 data, all 45 hospitals audited passed the audit with <5% discrepancy.26

### 6 FUTURE PERSPECTIVES AND SUMMARY

Establishment and development of the NCD was largely influenced by American College of Surgeons National Surgical Quality Improvement Program (ACS-NSQIP), sharing the same goal of providing the best medical care and maintaining a high standard of care for all patients. Although there are substantial differences in the health-care systems between Japan and the USA, the level of surgical quality and safety within each country is among the best in the world and would serve as a good model for other countries to emulate.

In Europe, there are surgical data registries such as Eurostat (https://ec.europa.eu/eurostat/web/main/home) or the European Society of Thoracic Surgery Database (ESTSD),27 but they use restricted variables or different formats compared with NCD/NSQIP. Although European counterparts of NCD/NSQIP are not present, it might be possible to compare basic characteristics among international registries such as demography, length of hospital stay, and mortality after specific procedures, which would be very interesting and important as a future project.

Through participating in large nationwide registries such as NCD and NSQIP, the risk-adjusted mortality and morbidity rate in both countries has decreased significantly after only a few years of participation, suggesting that the use of large data sets in health care is effective at improving surgical care and is important for the future. Moreover, we are facing increasing obstacles in the future of health care with an aging society and high costs of medical care, and participating in continued efforts such as these to improve surgical quality will help us overcome these challenges.

The collaboration between JSGS and ACS on these joint projects will continue to provide us with important information and data to drive improvements in surgical care. The data from the risk calculators project will provide us with an internationally validated calculator and will also help us determine specific features of surgical care that impact each country differently. This will also help us to identify any unknown weaknesses in the health-care systems of the USA and Japan. Our collaborative partnership between JSGS and ACS remains strong, and we look forward to continuation of the important work being done with reviews of the studies as these two organizations work together to improve surgical care on an international basis.
