Subtilisin NAT, a Bacillus subtilisin, is widely applied as a functional food and considered to be one of the most exploitable potential oral thrombolytic agents. Subtilisin QK, another Bacillus subtilisin, is a serine protease fermented by Bacillus subtilis 02 and has a better thrombolytic effect. Therefore, subtilisin QK is typically used for evaluating the safety of Bacillus subtilisins. Here, we conduct several good laboratory practice (GLP)-compliant studies in non-rodent animal, i.e., in Beagle dogs, including acute toxicity, subchronic toxicity, and safety pharmacology studies. No adverse effects were evident in the acute and 28-d subchronic toxicity studies at doses up to 40000 FU/kg and 16000 FU/kg/d, respectively. In evaluating the pharmacological safety of up to 2000FU/kg subtilisin QK, we found no significant differences between the electrocardiograms, blood pressures, and respiration of beagle dogs. These findings suggest the safety of Bacillus subtilisin, providing reliable pharmacological and toxicological data for its development and popularization as a functional food and drug.

Key words Bacillus subtilisin; subtilisin QK; acute toxicity; subchronic toxicity; safety pharmacology

INTRODUCTION

Coronary heart disease, stroke, and venous thromboembolism are serious threats to human health, with thrombosis being one of the major causes of these diseases. However, safe and effective oral thrombolytics for the preventing and treating these diseases are unavailable. Bacillus subtilisins, a class of serine proteases secreted by Bacillus subtilis, are considered to effective thrombolytic agent with great exploitable potential owing to their ability to efficiently degrade cross-linked fibrins. Recently, their importance in the improvement of blood circulation is gradually increasing. For example, subtilisin NAT, is widely used as a functional food for preventing cardiovascular and cerebrovascular diseases.

Subtilisin NAT is a fibrinolytic enzyme derived from natto fermented with Bacillus subtilis NAT was officially named “nattokinase” by Sumi in 1987. Subtilisin NAT is a serine protease with a good of thrombolytic effect. In vitro, the same molar amount of subtilisin NAT degraded cross-linked proteins six times more efficiently than plasmin. Additionally, its efficiency at degrading blood clots was >4–5 times that of plasmin. Subtilisin NAT also reportedly promotes thrombolysis in vivo. For example, it efficiently dissolved the thrombus in a tail vein thrombosis rat model. It also lysed the thrombus in a chemically induced rat carotid artery model more effectively than plasmin. Subtilisin NAT not only directly degrades cross-linked fibrins but also activates endogenous urokinase-type plasminogen activator (u-PA) and tissue plasminogen activator (t-PA), which further activate plasmin, which enhances fibrinolysis. Additionally, it can reduce coagulation factor VII and VIII levels in humans and inhibit platelet aggregation, thus, reducing the risk of thrombosis. A couple of recent clinical trials have shown that oral subtilisin NAT can improve blood circulation and reduce cardiovascular disease risk. Because of its significant thrombolytic and anticoagulation effects, subtilisin NAT is a widely used functional food worldwide. Despite this, toxicological data on Bacillus subtilisin remain limited, with only a few reports of the toxicity of subtilisin NAT in mice and Sprague-Dawley (SD) rats. Its maximum daily tolerance dose is reportedly 480000 FU/kg in mice and 21900 FU/kg/d in rats. A single oral administration of 49400 FU/kg subtilisin NAT in rats resulted in no obvious toxicity. The assessment of the potential toxicity of Bacillus subtilisin is limited by data unavailability. Therefore, this study aimed at assessing the safety of Bacillus subtilisin in beagle dogs using subtilisin QK.

Subtilisin QK, a serine protease produced by the fermentation of Bacillus subtilis QK02, is highly homologous with subtilisin NAT (98.78% identical). Similar to subtilisin NAT, subtilisin QK consists of 275 amino acid residues (MW = 27.8kDa). However, subtilisin QK reportedly has a more effective thrombolytic effect. It degrades cross-linked fibrins and has strong thrombolytic capacity in thrombotic mouse models. In the present study, a relatively large dose of subtilisin QK was used to conduct acute toxicity, repeated dose toxicity, and safety pharmacology studies in non-rodent animals, i.e., beagle dogs under good laboratory practice (GLP) conditions. This study aimed at providing reliable pharmacological and toxicological data for Bacillus subtilisin, to aid the popularisation of their use as functional foods and drugs.

MATERIALS AND METHODS

Materials and Dose Selection Subtilisin QK, derived...
from the liquid fermentation of Bacillus subtilis QK02, was provided by Wuhan Zhenfu Pharmaceutical Co., Ltd. (Wuhan, China). The fermentation broth was made into a powder by centrifugation, microfiltration, ultrafiltration concentration, and spray drying. The isolated enzyme was identified using the fibrin plate method. Meanwhile, the microbial limit, pH, biological activity, moisture, molecular weight, protein content, and percentage of the spray dried powder were evaluated. Analytical data from tests on three batches of subtilisin QK are presented in supplementary Table 1. Zoletil (6W9K, Virbac, France) was used to anesthetize beagle dogs in all experiments (the injection dose was 15 mg/kg body weight and the injection volume was 0.3 mL/kg body weight). According to the low dose of mouse drug effect (1000 FU/kg), the equivalent dose of Beagle dog is about 200 FU/kg. In acute toxicity experiment, in order to obtain more toxicity data, the dose of this test is designed to be 20000 and 40000 FU/kg, which were approximately 100 and 200 times the equivalent dose of Beagle dogs. In subchronic toxicity test, the low, medium, and high doses were designed to be 1000, 4000, and 16000 FU/kg, respectively, which were approximately 5, 20, and 80 times the equivalent dose of Beagle dogs. In pharmacology experiment, in order to obtain more toxicity data, the dose of this test is designed to be 20000 and 40000 FU/kg, which were approximately 100 and 200 times the equivalent dose of Beagle dogs. In acute toxicity test, the low, medium, and high doses were designed to be 1000, 4000, and 16000 FU/kg, respectively, which were approximately 5, 20, and 80 times the equivalent dose of Beagle dogs. In pharmacology experiment, in order to obtain more toxicity data, the dose of this test is designed to be 20000 and 40000 FU/kg, which were approximately 100 and 200 times the equivalent dose of Beagle dogs.

Animal Husbandry and Maintenance Healthy 8–10-months-old female and male beagle dogs, were purchased from Qingdao Bolong Experimental Animal Co., Ltd. (Qingdao, China), and quarantined and fed for 35 d, for adaptation. They were all housed in the common-level breeding room at the Suzhou drug safety evaluation and research center (animal license number: SYXK (Su) 2016-0042), maintained at 22 ± 2°C, 50 ± 10% relative humidity, a 12h:12h light and dark cycle, and ≥8 minimum air change times per hour. All experimental procedures were conducted in conformity with institutional guidelines for the care and use of laboratory animals in Wuhan University, Wuhan, China, and conformed to the National Institutes of Health Guide for Care and Use of Laboratory Animals.

Acute Toxicity Study Six beagle dogs were randomly allocated to three groups (a female and a male in each group). Each was administered a single dose of 0 (control), 20000, or 40000 FU/kg subtilisin QK (enteric-coated capsule). Clinical signs of toxicity were very closely monitored at 1, 3, and 6 h post administration, and twice daily during the 14-d observation period. The body temperatures of all animals were recorded before administration and 1, 3, 6, and 24 h post administration. The body weights of all animals were recorded before administration and 2, 7, and 14 d post administration. Electrocardiography, haematology, blood biochemistry and coagulation were performed before administration, and 2 and 14 d post administration. All blood samples were evaluated within 2 h of collection. On day 15, all animals were euthanized by exsanguination after intramuscular anaesthesia and were subjected to gross necropsy.

Subchronic Toxicity Study

Experimental Design

Forty beagle dogs were randomly assigned to four groups (5 females and 5 males in each group). They were administered 0 (control), 1000, 4000, or 16000 FU/kg subtilisin QK (enteric-coated capsules) daily for 28 d. At the end of the dosing period (D29), 3 males and 3 females from each group were randomly selected for pathological examination. The remaining animals (2 males and 2 females in each group) were continuously monitored for 28 d (recovery period). At the end of the recovery period (rD29), all remaining animals were euthanised and pathologically examined.

Note: D0, before the dosing day; D1, first day of dosing; rD1, first day of the recovery period (by analogy with other experimental data).

Clinical Observations and Measurements

Clinical signs of toxicity were monitored twice daily during the dosing and recovery periods. The food consumption of each animal was measured daily. The body weights of each animal were recorded on D0, D7, D14, D21, D28, rD7, rD14, rD21, and rD28. The body temperatures of each animal were recorded on D0, D14, D28, and rD28.

Ophthalmoscopy and Electrocardiography

The eyes (eyelid, conjunctiva, cornea, sclera, iris, pupil, lens, vitreous, and fundus) of each animal was examined with an eye examination slit lamp microscope and a binocular indirect ophthalmoscope on D0, D28, and rD28. On D0, D14, D28, and rD28, electrocardiogram of each animal was taken for heart rate, PR interval, QT interval, QR interval, P wave, R wave, T wave, and ST interval by using electrocardiography (ECG-I103G Vet, Carewell, China). QTc were calculated using the equation QTc = QT − 0.087 (RR−1000).

Urinalysis

Urinalysis samples were collected from all animals on D0, D13, D27, and rD27, and analysed within 2 h. Colour (CLO), pH, turbidity (TURB), nitrite (NIT), glucose (GLU), specific gravity (SG), occult blood (BLD), protein (PRO), bilirubin (BIL), urobilinogen (URO), and ketones (KET) were determined using a urine chemistry analyzer (AUTION MAX AX-4280, ARKRAY, Japan).

Haematology, Blood Biochemistry and Coagulation Parameters

On D0, D14, D28, and rD28, each animal was subjected to venous blood collection using ethylenediaminetetraacetic acid (EDTA)-K2 and sodium citrate-coated tubes, and an inert separating gel coagulant tube, chronologically. The blood samples collected in the EDTA-K2-coated tubes were analyzed for haematology using an auto-hematology analyzer (XT-2000iV, SYSMEX CORPORATION, Japan). Na+, K+, and Cl− were determined using an electrolyte analysis instrument (XI-931T, Shenzhen City Kate Bio-Medical Electronics Co., Ltd., China). Blood biochemistry was determined using an automatic biochemistry analyzer (c8000, Abbott Laboratories, U.S.A.). The blood samples collected in sodium citrate-coated tubes. Plasma was separated for coagulation detection using an automated coagulation analyzer (STAGO STA-R Evolution, DIAGNOSTICA STAGO, France).

Histopathology

On D29 and rD29, 24 and 16 beagle dogs were individually euthanized by exsanguination after intramuscular anaesthesia, respectively. Their organs were then harvested for histological studies. Organ weights (brain, thymus, kidney, adrenals, thyroid, liver, spleen, testis, epididymis, uterus, ovaries) were recorded, and the relative organ weights were calculated using the formula relative organ weight = absolute organ weight (g)/ Body weight (g) × 100%. In addition, samples were collected
from the sternum of all animals to take a bone marrow smear for bone marrow cell categorization and quantification.

Immunotoxicity

Blood biochemical analysis was used to determine white/ball ratio and the levels of albumin, globulin, immunoglobulin G (IgG), immunoglobulin M (IgM), complement 3 (C3), complement 4 (C4), and circulating immune complex (CIC). The T lymphocyte phenotype of Peripheral blood form each animal was determined using a flow cytometry (AFC2, Thermo Fisher Scientific, U.S.A.). White blood cells types, counts, and percentages were analysed to investigate the effects of subtilisin QK on peripheral blood leukocytes. The immune system of each animal (spleen, thymus, and lymph nodes) was subjected to gross pathological and histopathological examinations.

Pharmacology Safety Study Eight beagle dogs were randomly allocated to 4 groups (a female and a male in each group, according to the $4 \times 8$ Latin square design plan, as the supplementary Table 2), and administered a single dose of 0 (control), 200, 500, or 2000 FU/kg subtilisin QK (enteric-coated). After each administration, at least 7 d of washing period should be used before the next administration. During the four dosing cycles, electrocardiogram (ECG), blood pressure parameters, and respiratory parameters of each animal were measured using the emka PACK 4G telemetry system (emkaPACK 4G, EMKA Technologies, France). All animals were subjected to adaptive training prior to data collection. ECG values (heart rate, PR interval, QT interval, QRS interval, P wave, R wave, T wave, ST interval, and QTc) and respiratory parameters (respiratory frequency and tidal volume) were measured continually from 0.5h prior to dosing until 24h after dosing. Blood pressure (systolic and diastolic blood pressure) was measured 15min prior to dosing, and at 0.5, 1, 2, 4, 6, 8, and 24h after dosing. ECG, blood pressure, and respiratory parameters measured at the mentioned time points were processed using the ECG auto analysis software of emka PACK 4G telemetry system (emkaPACK 4G, EMKA Technologies).

Data Processing The Levene’s test was used to test the homogeneity of variance. If the variance was uniform...
(p > 0.01), the ANOVA results were directly used to determine the statistical significance of the overall difference. If the variance was not uniform (p ≤ 0.01), the statistical significance of the overall difference was judged using results from the Welch test. If the ANOVA or Welch test results were statistically significant, multiple comparisons of differences between groups were performed using the Bonferroni test to further determine which differences between groups were statistically significant. p < 0.05 was considered statistically significant.

RESULTS

Acute Toxicity Study During the 14-d observation period, no animals died. Soft stool was observed in 1 female in the 40000 FU/kg/d group on the dosing day. The body weights of the females in the control and 40000 FU/kg/d groups were slightly decreased. No obvious abnormalities in body temperature, electrocardiogram, haematology, blood biochemistry and coagulation parameters were observed in the dosing and control groups. Similarly, macroscopic examinations revealed no significant pathological changes. (Supplementary Tables 3–8)

Subchronic Toxicity Study
Clinical Observations and Measurement
During the 28-d dosing or recovery periods, no animals died. Soft stool was occasionally found in the dosing and control groups. In comparison with the control groups, there were no significant differences in the mean body weights, mean food consumption, and mean body temperatures of animal in the dosing groups (Figs. 1–3).

Ophthalmoscopy and ECG
No obvious abnormality was observed in the eyes of all animals’ (data not shown). Similarly, there were no statistically significant differences between the ECG of the dosing and control groups on D0, D14, D28, and rD28 (Supplementary Table 9).

*p < 0.05 compared to the control group. TT, Thrombin time; PT, Prothrombin time; FIB, Fibrinogen; APTT, Activated partial thromboplastin time; S.D., Standard deviation.
There were no significant differences in the urinalysis results of the dosing and control groups (data not shown). Compared with the control group, there was a statistically significant shortening of prothrombin time (PT) in the 4000 FU/kg/d group males on D14 and D28 ($p < 0.05$), but similar with the pre-dosing data of themselves. The fibrinogen (FIB) values in the 1000 FU/kg/d group males on D14 were slightly shorter than those in the control group (Table 1a). There were statistically significant decreases in the reticulocyte ratio (RET %) of the 4000 and 16000 FU/kg/d group males on D28, and eosinophil ratio (EO %) was increased in the 16000 FU/kg/d group males on D28, compared with the control group ($p < 0.05$), but not statistically significant difference with their own previous data (Supplementary Table 10a). Total bilirubin (TBIL) was reduced in the 4000 FU/kg/d group males on D0, and triglyceride (TG) was increased in the 1000 FU/kg/d group males on D28, compared with the control group ($p < 0.05$). There were no statistically significant differences in the urinalysis results between the control and treatment groups (Table 1b). Additionally, there were no statistically significant decreases in the reticulocyte ratio (RET %) of the 16000 FU/kg/d group females relative to controls. Therefore, these outcomes were not considered subtilisin QK treatment related (Table 2b). Compared with control group, there were significant increases in the mean absolute and relative uterine weight of the 1000 FU/kg/d group females, but not statistically significant difference (Table 2b). These findings were not considered to be related to subtilisin QK treatment. Additionally, there were no statistically significant differences in other organs between the doing and control groups (Table 3).

**Histopathology**

The histopathology results of the control (0 FU/kg/d), low dose (1000 FU/kg/d), middle dose (4000 FU/kg/d), and high dose (16000 FU/kg/d) groups are shown in supplementary Table 12. The pathological changes were considered spontaneous or sporadic because the background lesions of the beagle dogs in the control, low dose, middle dose, and high dose groups were not significantly related to subtilisin QK. In addition, no abnormal bone marrow was observed in any of the animals.

**Immunotoxicity**

There were no statistically significant differences in serum immune parameters, peripheral blood T lymphocyte, and T lymphocyte typing of all treatment groups (Supplementary Table 13). A female beagle in the 16000 FU/kg/d dose group had a mild atrophy of the thymus. However, histopathological

examinations showed no obvious abnormalities in the thymus, and there were no significant differences in the relevant biochemical indicators. Additionally, no pathological damages were observed in thymus, spleen and lymph nodes (mesenteric and submandibular lymph nodes). Therefore, this finding was not considered to be related to subtilisin QK treatment.

**Safety Pharmacology Study**  During the 4 dosing periods, no animals died, and no obvious clinical symptoms were observed in the animals of each group. Compared with the pre-treatment data and those of the control group, there were no statistically significant changes in the electrocardiogram (heart rate, PR interval, QT interval, QRS interval, P wave, R wave, T wave, ST segment, and QTc values), blood pressure (systolic blood pressure, diastolic blood pressure, and average pressure), and respiratory parameters (respiratory frequency and tidal volume) of the dosing groups (Supplementary Tables 14, 15).

**DISCUSSION**

At present, thrombotic vascular diseases are severe and safe and effective oral thrombolytic drugs are lacking. Many fibrinolytic enzymes such as urokinase, streptokinase, and t-PA, reportedly have good thrombolytic effects.\(^{23,24}\) However, treatment with those agents is accompanied by adverse effects, such as bleeding.\(^{25}\) Therefore, they are not suitable for the long-term prevention and treatment of cardiovasc-ular and cerebrovascular thrombotic diseases. The effects of *Bacillus subtilis* in diseases such as thrombosis, hyperlipemia, hypertension, and atherosclerosis have been extensively studied.\(^{26-28}\) Specifically, in thrombosis-related diseases, their advantages include an excellent thrombolytic effect, high specificity, and few side effects. Therefore, *Bacillus subtilis* are natural oral thrombolytic proteins with significant development potential. Although Chinese Dou-chi, Japanese natto, Korean Chunggok-Jang, and Indian kinema have been used as food for >1000 years with no incidence of adverse effects,\(^{29}\) the toxicological data of *Bacillus subtilis* remain limited.

The toxicity of subtilisin NAT in mice and Sprague-Dawley (SD) rats has recently been reported. A single oral administration of 49400 FU/kg subtilisin NAT to rats resulted in no animal deaths and no obvious pathological changes after 14 d.\(^{19}\) Moreover, daily administration of 480000 FU/kg subtilisin NAT to mice for 4 d reportedly resulted in no obvious toxicity.\(^{29}\) Additionally, daily administration of 3340 FU/kg subtilisin NAT to rats for 28 d had no significant effects on their urinalysis and histopathological examination results.\(^{19}\) Furthermore, daily administration of 21900 FU/kg subtilisin NAT to rats for 28 d had no significant effects on their urinalysis and histopathological examination results.\(^{19}\) It was reported that the use of rodent for predicting human toxicity with a concordance rate of 43%.\(^{30}\) The assessment of the safety of *Bacillus subtilis* is limited by the lack of information on its toxicity in non-rodsents. Therefore, in the present study, we conducted a series of safety assessment experiments

\(n=3\)
with subtilisin QK in beagle dogs, to elucidate the safety of *Bacillus* subtilisin.

For the present study, a single dose of 40000 FU/kg subtilisin QK to beagle dogs resulted in no adverse effects. Subsequently, to observe the toxicity and dose-response relationship of subtilisin QK, beagle dogs were administrated daily dose at 0, 1000, 4000, and 16000 FU/kg for 28 d. Compared with the control groups, there were statistically significant increase in the EO % of the 16000 FU/kg/d group males on D28 ($p < 0.05$). However, there were no adverse clinical signs and no abnormal IgG or IgM in the 16000 FU/kg/d group (Supplementary Table 13). In addition, compared with the control groups, the body weights, food consumption, and body temperatures of the 16000 FU/kg groups were normal (Figs. 1–3). There was also no abnormal in the acute toxicity study. Besides, in another study of subchronic toxicity in rats, we used a large number of rats, but eosinophil levels were not abnormal (data not published). Therefore, it is almost impossible for subtilisin QK to cause food allergies. These results indicated that the maximum dose of subtilisin QK had no significant toxic effect in this study. The results were similar to those obtained post repeated dosing of subtilisin NAT in rats and mice.$^{19, 29}$ To observe the reversibility of toxic effects and possible delayed toxicity, 16 beagle dogs were continually monitored for 28 d after the 28 d repeated administration period and no delayed toxicity was observed. Furthermore, subtilisin QK cause no significant immunotoxicity effects in beagle dogs. Due to the lack of adverse effects during the acute and subchronic toxicity studies, we conducted safety pharmacology studies in the beagle dogs.

Safety pharmacology studies are used to determine the predicted and unpredicted side effects of drugs. Generally, the safety pharmacology core battery of tests that must be completed, including the central nervous, cardiovascular and respiratory systems.$^{31}$ Thus, the emka PACK 4G telemetry system was used to detect the ECG, blood pressure, and respiration of the beagle dogs. Compared with the pre-dosing data and those of the control group, there were no significant differences between the QT and QTc interval of all dosing groups. Moreover, the blood pressure and respiration of the treated dogs were not significantly affected. Based on these findings, the maximum dose of subtilisin QK used in the acute toxicity, 28-d toxicity, and the safety pharmacology studies were up to 40000, 16000, and 2000 FU/kg, which were about 200, 80, and 10 times higher than the equivalent dose of Beagle dog (about 200 FU/kg), respectively. Despite this, there were no significant physiological changes and toxic (tissue and organ) effects in the subtilisin QK-treated dose groups.

**CONCLUSION**

In summary, *Bacillus* subtilisin is a popular functional food with great potential in cardiovascular and cerebrovascular disease prevention and treatment. Subtilisin QK, a *Bacillus* subtilisin, also has many potential benefits for humans. In this study, we found that the administration of a single dose of up to 40000 FU/kg, and repeated daily doses of up to 16000 FU/kg to male and female beagle dogs resulted in no obvious toxic effects. No adverse effects were observed in the cardiovascular, central nervous, and respiratory systems of beagle dogs post daily administration of up to a dose limit of 2000 FU/kg subtilisin QK. Based on these results, the no-observed-adverse-effect level (NOAEL) in beagle dogs following a 28-d repeated dosing exposure to oral subtilisin QK is 16000 FU/kg/d.
