Abstract. Simultaneous observations of a polarized Micro-Pulse Lidar (P-MPL) system, routinely operative at the NASA Micro-Pulse Lidar Network/El Arenosillo site, with two reference European Aerosol Research Lidar Network lidars, running at the Leipzig site (Germany, 51.4ºN 12.4ºE, 125 m a.s.l.), were performed during a comprehensive two-month field intercomparison campaign in summer 2019. An experimental assessment regarding both the overlap (OVP) correction of the P-MPL signal profiles and the volume linear depolarization ratio (VLDR) analysis, together with its impact in the retrieval of the aerosol optical properties, is achieved, describing also the experimental procedure used. The optimal lidar-specific OVP function for correcting the P-MPL measurements is experimentally determined, highlighting that the OVP function as the one delivered by the P-MPL manufacturer cannot be long used. Among the OVP functions examined, the averaged one between those obtained from the comparison of the P-MPL observations with those of the other two reference lidars seems to be the best proxy at both near- and far-field ranges. In addition, the impact of the OVP function in the accuracy of the retrieved profiles of the total particle backscatter coefficient (PBC) and the particle linear depolarization ratio (PLDR) is examined. First, the volume linear depolarization ratio (The VLDR) profile is obtained and compared to that derived from the reference lidars, showing it needs to be corrected by a small offset value within a good accuracy. Once P-MPL measurements are optimally (OVP, VLDR) corrected, both the PBC and PLDR profiles can be accurately derived, being in good agreement with reference aerosol retrievals. In overall, as a systematic requirement for lidar systems, an adequate OVP function determination and VLDR testing analysis is needed to be determined performed in a regular basis to correct the P-MPL measurements, together with a slightly VLDR correction, in order to derive suitable aerosol products. A dust event as observed at Leipzig in June 2019 is used for illustration. The experimental methodology shown in this work can be easily applicable to other P-MPL systems.

1 Introduction

Active remote sensing is an excellent tool for vertical monitoring of the atmosphere. In particular, aerosol lidar systems have demonstrated to be a suitable instrumentation for aerosol and cloud profiling in both the troposphere and stratosphere (e.g., Amiridis et al., 2015; Baars et al., 2019). Tropospheric aerosols are usually confined up to 7-8 km height under aerosol intrusion conditions (e.g., Mattis et al., 2008; Pappalardo
et al., 2013); otherwise, they are mostly concentrated in the ABL (around less than 1.5 km height). Indeed, lidar systems are widely used due to their high vertical spatial and temporal resolution. Ground-based lidar networks are widely operative within the GAW (Global Atmospheric Watch) Aerosol Lidar Observations Network (GALION); among them, there are those extended at continental scales, as EARLINET (European AeRosol Lidar NETwork, www.earlinet.org; Pappalardo et al., 2014), which belongs also to the Aerosol Cloud and Trace Gases Research Infrastructure (ACTRIS, www.actris.eu), ADNET (Asian Dust and aerosol lidar observation network, www-lidar.nies.go.jp/AD-Net; Sugimoto et al., 2008), and LALINET (a.k.a. ALINE, Latin American Lidar NETwork, www.lalinet.org; Barbosa et al., 2014). In addition, there are other aerosol networks like MPLNET (Micro-Pulse Lidar NETwork, mplnet.gsfc.nasa.gov; Welton et al., 2001), within GAW/GALION, and PollyNET (POrtabLe Lidar sYstem NETwork, http://polly.tropos.de; Baars et al., 2016), operated as a part of EARLINET, whose sites are distributed around the world.

The use of the lidar observations with polarization capabilities is increasing as the lidar depolarization measurements allow a better aerosol speciation (dust, marine aerosol, anthropogenic pollution, volcanic ash, biomass burning, pollen, …) as well as the separation of the optical properties (backscatter, extinction) of particle components within complex aerosol mixtures with vertical resolution (i.e., Ansmann et al., 2011; Burton et al., 2014; Yu et al., 2015; Córdoba-Jabonero et al., 2018; Bohlmann et al., 2019). Therefore, new and promising methods based on the particle depolarization ratio were developed and used to derive aerosol profiles in terms of particle mass concentration, separately for the coarse and fine modes (i.e., Mamouri and Ansmann, 2017), in addition to estimate both the cloud-condensation nuclei (CCN) and ice-nucleating particle (INP) concentrations (i.e., Mamouri and Ansmann, 2016).

The atmospheric lidar scanning provides an accurate characterization at all ranges; however, lidar systems present an incomplete response in the near-range observational field due to the partial intersection of the field-of-view between the transmitter and the receiver for both the biaxial and coaxial lidar configurations. Therefore, lidar signal profiles must be corrected by this near-field loss of signal, that is, the overlap (OVP) correction (Wandinger and Ansmann, 2002). The full-OVP height depends on the lidar system (e.g., Wandinger et al., 2016).

During the last two decades, the Micro-Pulse Lidar (MPL) systems (Campbell et al., 2002; Welton et al., 2002; manufacturer: Sigma Space Corp., currently Droplet Measurement Technologies) were deployed at different latitudes and many of them in the frame of MPLNET; since few years a polarized MPL version (P-MPL) is the standard lidar system in this network. Both MPL and P-MPL observations have been widely performed for continuous monitoring of aerosols and clouds. In particular, MPL/P-MPL measurements were used for: Atmospheric Boundary Layer (ABL) height retrievals (Lewis et al., 2013; Toledo et al., 2014, 2017), for detection and characterization of both cirrus clouds (Campbell et al., 2016; Lewis et al., 2016; Córdoba-Jabonero et al., 2017; Lolli et al., 2017; Campbell et al., 2021) and Polar Stratospheric Clouds (PSC) (Campbell et al., 2008; Córdoba-Jabonero et al., 2013), for depolarization-based characterization of the optical properties of different aerosol mixtures (Sicard et al., 2016; Córdoba-Jabonero et al., 2016, 2018), for aerosol mass concentration estimation either in synergy with airborne measurements (Córdoba-Jabonero et al., 2016) or in comparison with forecast model simulations (Córdoba-Jabonero et al., 2019), for determination of the precipitation intensity determination (Lolli et al., 2018; Lolli
et al., 2020); for determination of the cloud thermodynamic phase (Lewis et al., 2020) and for assessment of the radiative effect of aerosols and cirrus clouds (Campbell et al., 2016; Lolli et al., 2017; Córdoba-Jabonero et al., 2020, 2021; Campbell et al., 2021; Sicard et al., 2021), among others. Those works have demonstrated a good MPL performance in aerosol/cloud research. The P-MPL is an elastic coaxial single-wavelength (532 nm) system and, differing from older MPL versions (Campbell et al., 2002; Welton et al., 2002), incorporates depolarization capabilities (Flynn et al., 2007). As a value-added improvement, it can operate in routine continuous (24/7) mode. However, the P-MPL system needs to be well characterized in terms of the backscattered lidar signal detected by both depolarization channels of the instrument (Flynn et al., 2007; Welton et al., 2018) in order to retrieve plausible aerosol optical properties. In particular, due to the very narrow telescope field of view, the lidar system is reaching the full-OVP height at relatively high altitudes (typically at 4-6 km height; Campbell et al., 2002), being particularly relevant for tropospheric aerosol research. For this reason, an accurate overlap correction, among other features, is needed for MPL systems.

MPLNET have established methods for overlap calibration, as those described in Berkoff et al. (2003). They are based on either performing measurements under atmospheric stable and homogeneous conditions with the MPL pointing in horizontal, or making use of a secondary wide field-of-view receiver (WFR) telescope. However, both of them could not be yet applied on site to the MPL system examined in this study. Hence, an alternative experimental procedure for the OVP function determination is introduced in this work, which is based on the cross-comparison of the backscattered signal recorded by the uncorrected lidar system (our MPL) with respect to that collected by a reference (overlap-corrected) lidar. A similar methodology has been also used for the overlap correction of other lidars and ceilometers (i.e., Guerrero-Rascado et al., 2010; Sicard et al., 2020; and references therein). In this framework, an experimental campaign was planned at the EARLINET Leipzig site (Germany, 51.4°N–12.4°E, 125 m a.s.l.), and, in particular, devoted to simultaneously compare the observations of a P-MPL system with reference well-calibrated lidar measurements in order to determine the required P-MPL evaluation performance. The aim of this work is threefold: 1) to achieve an OVP correction of the P-MPL system, i.e., to estimate the experimental OVP function for correcting the P-MPL measurements; 2) to evaluate the volume linear depolarization ratio (VLDR), which is a lidar-derived parameter independent of OVP correction; and 3) to determine the P-MPL correction-induced effects on the retrieval of optical properties, both the height-resolved particle backscatter coefficient (PBC) and particle linear depolarization ratio (PLDR).

Section 2 introduces the methodology for that purpose: an overview of the field intercomparison campaign performed, a brief description of both the P-MPL and reference lidar systems used, and the data analysis of the experimental approaches applied for the data analysis, regarding the experimental estimation of the OVP function of the P-MPL system (error processing is described in Annex A), the evaluation of the VLDR, and the retrieval of the particle optical properties are particularly described: the experimental procedure for accurately characterizing the OVP function of the P-MPL systems, the correction of the VLDR, and the determination of the optical properties. Results are presented in Section 3, regarding the experimental estimation of the OVP function (error processing is described in Annex A), the evaluation of the VLDR, and the retrieval of the particle optical properties. A dust case as observed during the field campaign is used for that purpose. Main conclusions are presented in Section 4.
2 Methodology

2.1 Field campaign overview

During a field campaign carried out at the EARLINET station of Leipzig, Germany (51.35°N, 12.43°E, 125 m a.s.l.), managed by the Leibniz Institute for Tropospheric Research (TROPOS), for 6 weeks in June-July 2019, the performance of a P-MPL system was experimentally evaluated, with a special emphasis on the OVP correction and VLDR evaluation. The lidar system used was the MPL44245 unit (formerly Sigma Space Corp., currently Droplet Measurement Technologies) routinely operating at the MPLNET/El Arenosillo station (https://mplnet.gsfc.nasa.gov/data/all&s=El_Arenosillo), sited at Huelva, Spain (ARN/Huelva, 37.1°N 6.7°W, 40 m a.s.l.), which is managed by the Spanish Institute for Aerospace Technology (INTA). Both stations are also AERONET (AErosol RObotic NETwork, aeronet.gsfc.nasa.gov) sites, accomplishing the requisite for co-location of both networks for the elastic retrieval of the aerosol optical properties. For the campaign, the ARN/Huelva P-MPL was temporarily deployed outside MPLNET at Leipzig to be compared against two EARLINET lidars routinely operative in this station, as Polly (POrtable Lidar sYstem; Althausen et al., 2009; Engelmann et al., 2016) and MARTHA (Multiwavelength Tropospheric Raman lidar for Temperature, Humidity, and Aerosol profiling; Jiménez et al., 2018) systems. They were used as reference because these lidars are well characterized with respect to EARLINET quality assurance standards (e.g., Böckmann et al., 2004; Pappalardo et al., 2004; Freudenthaler et al., 2008; Pappalardo et al., 2014; Wandinger et al., 2016; Belegante et al., 2016; Bravo-Aranda et al., 2016; Freudenthaler et al., 2016).

2.2 Lidar systems

2.2.1 Polarized Micro-Pulse Lidar (P-MPL)

The P-MPL system (Sigma Space Corp./Droplet Measurement Technologies, v. MPL-4B) is the standard lidar currently operating within MPLNET. It is an elastic lidar in coaxial configuration with depolarization capabilities operating in full-time (24/7) mode. Among the principal optical features, the Nd-YVO₄ laser emission at 532 nm, with a pulse energy of 6-8 μJ and a repetition rate of 2500 Hz, is recorded by a unique avalanche photodiode detector (APD), and the receiver system presents a field-of-view (FOV) of 80 μrad full angle and the telescope diameter is 18 cm wide (Sigma Space Corp., MPL system information handbook, 2018). P-MPL vertical profiles are routinely acquired with 1-min integrating time and 15-m vertical resolution (in particular, for the ARN/Huelva P-MPL system) up to 30 km height. Main instrumental features of the P-MPL system are shown in Table 1.

Table 1: Main instrumental features of the lidar systems.

| Lidar system | P-MPL | Polly | MARTHA |
|--------------|-------|-------|--------|
| Routine operation | 24/7 | 24/7 | Supervised |
| Lidar Networks | MPLNET | EARLINET | EARLINET |
| Transmitter properties | | |
| Wavelength (nm) | 532 | 532 (*) | 532 (*) |
| Energy/pulse (μJ) | 0.006-0.008 | 400 | 1000 |
The optical layout of the MPL-4B version is schematically shown in Flynn et al. (2007; see their Fig. 1). The laser light is alternatively transmitted linearly and circularly polarized to the atmosphere by switching between two retardation modes of a ferroelectric liquid crystal (FLC) rotator. The corresponding backscattered light to those two polarized states by passing through a beam splitter to the single APD is recorded in dependence of the polarizing or depolarizing atmospheric particles leading to the suppression or not, respectively, of the orthogonally-detected signal w.r.t. the transmitted one into the single APD. Those two polarized signals are semi-simultaneously detected by alternatively switching in the basis of 50%/50% the FLC polarization mode within every integrating minute. Note that the P-MPL pulse frequency is 2500 Hz, and the polarization state is switched every 250 pulses, but just 249 pulses are collected since one of the pulses is discarded during the FLC switching time (∼ 100 μs). That is, those two signals are alternatively detected by the same APD, being recorded in two polarized channels, i.e., the 532-nm cross-signal ($P_{\text{cross}}$) and the 532-nm co-signal ($P_{\text{co}}$) (see a more detailed description in Flynn et al., 2007). Therefore, since no potentially existing efficiency or alignment differences are between those two signal-channels (as used a single APD), no corrections for these effects are required, as it is typically needed for ordinary two-channel polarization lidars. Particular regular calibrations and signal processing were applied, which are the same as those described by Campbell et al. (2002) and Welton et al. (2002), and also by Flynn et al. (2007), whose data processing techniques remain also applicable for P-MPL systems, as indicated by Welton et al. (2018). Therefore, the measured lidar signal in those two polarized-channels is used to derive both the P-MPL total range-corrected signal (RCS), $P_{\text{MPL}}$, and the volume linear depolarization ratio (VLDR), $\delta^V$, by adapting the methodology as described in Flynn et al. (2007), that is, $P_{\text{MPL}} = P_{\text{co}} + 2 P_{\text{cross}}$, and

$$\delta^V = \frac{P_{\text{cross}}}{P_{\text{co}} + P_{\text{cross}}}.$$  

This data processing is currently applied for providing the MPLNET version 3 data products (Welton et al., 2018), besides having been successfully applicable in particular studies (e.g., Sicard et al., 2016; Córdoba-Jabonero et al., 2018; Lewis et al., 2020), independently of that established in MPLNET. Among the required routine instrumental P-MPL corrections (Campbell et al., 2002; Welton et al., 2002), the OVP is a concerning issue, since the typical full-OVP height is reached at rather high altitudes (usually at 4-5 km height), affecting thus the aerosol profiles at ranges in the overall boundary layer and part of the troposphere. Hence, an important issue to be achieved is the particular overlap correction function for this particular P-MPL system. Therefore, after sale, the P-MPL system is delivered with an original OVP.
function as provided by the manufacturer company (formerly Sigma Space Corp., currently Droplet Measurement Technologies), which, however, must be re-evaluated with time. Indeed, one of the goals of this work is to show the experimental procedure, similar to other usually applied (i.e., Guerrero-Rascado et al., 2010; Sicard et al., 2020), to obtain a new OVP function for the P-MPL lidar as compared to the original one (see later Sect. 2.3.1) together to examine its effects in the retrieval of the optical properties. This experimental methodology can be also applicable to other P-MPL systems.

2.2.2 POrtabLe Lidar sYstem (Polly)

The EARLINET Polly (POrtabLe Lidar sYstem) lidars are sophisticated, automated Raman-polarization lidar systems for scientific purpose, but with the advantage of an easy-to-use and well-characterized instrument with same design, same automated operation, and same centralized data processing delivering near-real-time data products. Polly systems have been developed and constructed at TROPOS with international partners since 2002 (Engelmann et al., 2016). All Polly lidar systems are designed for automatic and unattended operation in 24/7 mode. Meanwhile 12 Polly lidar systems are distributed around the globe (e.g., Baars et al., 2016). The Polly lidar system used as a reference in this comparison analysis, is the first one of the Polly family (Engelmann et al., 2016), which was substantially upgraded in 2016 (v. Polly_1v2). It emits linearly polarized light at 532 nm with 5 receiver channels: the elastically backscattered light at 532 nm, the cross-polarized light at 532 nm, the co-polarized light at 532 nm, the rotational-Raman scattered light near 532 nm, and the vibrational-rotational Raman scattered light at 607 nm. Its full-OVP is reached at around 300-500 m height, and thus preferred for the P-MPL OVP correction purpose. Profiles of the Polly range-corrected signal, $P_{\text{Polly}}$, are routinely derived by using sample settings with 7.5-m vertical resolution and 30-sec temporal integration. The main instrumental features of the Polly system are shown in Table 1.

2.2.3 Multiwavelength Atmospheric Raman lidar for Temperature, Humidity, and Aerosol profiling (MARTHA)

The second EARLINET lidar, which is used as a reference in this work, is the dual receiver field-of-view (RFOV) Multiwavelength polarization/Raman lidar for Temperature, Humidity, and Aerosol profiling (MARTHA) (Mattis et al., 2008; Schmidt et al., 2013, Jimenez et al., 2019). MARTHA has a powerful laser, transmitting in total 1 J per pulse at a repetition rate of 30 Hz, with an 80-cm telescope diameter, being thus well designed for tropospheric and stratospheric aerosol observations. This lidar system measures Raman signals at 532 nm ($P_{\text{MARTHA}}$, which is that used in this work) and 607 nm and the polarization-sensitive 532-nm backscatter signals at two RFOVs so that, besides aerosol profiles, cloud microphysical properties can be retrieved from measured cloud multiple scattering effects. MARTHA can provide the 532-nm particle depolarization ratio as measured with the smaller RFOV, and also the 355-, 532-, and 1064-nm particle backscatter coefficients and the 355- and 532-nm extinction coefficient profiles with their corresponding lidar ratio profiles. For this large telescope (and a selected receiver FOV of 0.5 mrad) the overlap between laser beam and receiver FOV is complete around 2000 m height. The overlap profile of this laboratory lidar is very stable. The main instrumental features of the MARTHA system are shown in Table 1.
The overlap (OVP) function, $F_{OVP}$, is used to correct the P-MPL (no OVP-corrected) RCS profiles, $P_{MPL}(z)$, as obtained from Eq. 1, at near-field altitudes, that is,

$$P_{OVP}(z) = P_{MPL}(z) / F_{OVP}(z),$$  

where $P_{OVP}(z)$ represents the overlap-corrected P-MPL RCS profiles.

In this work, the experimental procedure to obtain $F_{OVP}$ is based on the comparison of the $P_{MPL}(z)$ to either the Polly RCS profiles, $P_{Polly}(z)$, or the MARTHA ones, $P_{MARTHA}(z)$, which are both used as reference under relatively clean and mostly clear conditions. The Polly and MARTHA lidars present the advantage in contrast to P-MPL system that the OVP function can be experimentally determined using their Raman channels (Wandinger and Ansmann, 2002). The P-MPL overlap function is thus calculated in terms of the ratio between the P-MPL and Polly/MARTHA RCS profiles, i.e.,

$$F_{OVP}(z) = P_{Polly}(z) / P_{MPL}(z),$$  

where $P_{ref}(z)$ denotes the reference RCS profiles as obtained from either Polly, $P_{Polly}(z)$, or MARTHA, $P_{MARTHA}(z)$, measurements. Both sets of RCS profiles are normalized at a given height (higher than the OVP altitude range under aerosol-free conditions), $z_{norm}$, and then $F_{OVP}(z)$ can be derived using Eq. 3. In particular, the full-OVP is conservatively obtained at the normalization height $z_{norm} = 9.5$ km a.g.l., being $F_{OVP}(z) = 1$ at $z \geq z_{norm}$. Errors associated to the estimation of $F_{OVP}(z)$ using this experimental approach are described in Annex A. Night-time lidar observations performed under relatively clean conditions at the Leipzig station (AERONET AOD < 0.1 and AE > 1.2) were used for the P-MPL OVP determination. In particular, two time periods were selected in coincidence with either Polly or MARTHA observations in order to provide an extended comparison analysis using diverse reference lidar systems under different lidar operational conditions.

2.4 Retrieval of the aerosol optical properties: Particle backscatter coefficient, and both volume and particle linear depolarization ratios

Once the OVP-corrected RCS is obtained from Eq. 3, the particle backscatter coefficient (PBC), $\beta_p$ (km$^{-1}$ sr$^{-1}$) can be derived applying the Klett-Fernald (KF) algorithm (Fernald, 1984; Klett, 1985) by constraining the lidar ratio (LR, extinction-to-backscatter ratio) with the AERONET Aerosol Optical Depth (AOD) (elastic KF solution) (Marenco et al., 1997); hence, an effective LR, $S_{eff}$, is also obtained after convergence.

The particle linear depolarization ratio (PLDR), $\delta_p$, can be determined as follows,

$$\delta_p = \frac{R \delta V (1+\delta_{mol})-\delta_{mol} (1+\delta V)}{R (1+\delta_{mol})-(1+\delta V)},$$  

where $R$ is the backscattering ratio ($R = (\beta_m + \beta_p) / \beta_m$, being $\beta_m$ the molecular backscattering coefficient), $\delta^V$ is the volume linear depolarization ratio (VLDR), and $\delta_{mol}$ is the molecular depolarization ratio. For P-MPL systems, $\delta_{mol} = 0.0037$ for P-MPL systems that is, being almost independent on atmospheric conditions.
temperature (relative uncertainty < 0.1\%), as their FWHM is less than 0.2 nm (Behrendt and Nakamura, 2002). The PLDR is a lidar parameter widely used for defining the aerosol type (Burton et al., 2012; Gross et al., 2013), and for discriminating the particle size mode in some aerosol mixtures (Mamouri and Ansmann, 2017; Córdoba-Jabonero et al., 2018), among others. The determination of PBC is mainly depending on the OVP correction, as will be discussed in Sect. 3.3, and hence, the PLDR is also affected by OVP as well. Therefore, a good knowledge of the OVP function for the specific P-MPL system is also needed to obtain high-quality PBC and PLDR profiles.

The volume linear depolarization ratio (VLDR), \( \delta^V \), can be determined in relation with the P-MPL depolarization ratio, \( \delta^{\text{MPL}} \) (Mishchenko and Hovenier, 1995; Gimmestad, 2008). Looking at the formulae shown in Flynn et al. (2007; see their Eq. Fig. 1.8), \( \delta^V \) can be easily expressed as

\[
\delta^V = \frac{\delta^{\text{MPL}}}{\delta^{\text{MPL}} + 1} = \frac{p_{\text{cross}}}{p_{\text{co}} + p_{\text{cross}}},
\]

i.e., the Eq. 2 is obtained, where \( \delta^{\text{MPL}} \) is defined as the ratio between \( p_{\text{cross}} \) and \( p_{\text{co}} \) (the two polarized RCS as described in Sect. 2.2.1). Since the OVP function is equally applied to both those signals, the VLDR is unaffected by the OVP correction; however, it actually affects, together with the PBC, the PLDR estimation (see Eq. 5). Therefore, Hence, the VLDR for the P-MPL system was also experimentally evaluated examined in comparison with that derived from Polly lidar measurements, for instance, similarly to the approach shown by Córdoba-Jabonero et al. (2013). This experimental polarization correction is based on real measurements as an alternative (see Sect. 3.2), due to the unavailability of applying the special and specific methods for polarization calibration within MPLNET, as those described in Welton et al. (2018).

All those variables are height-resolved, but the altitude dependence is omitted for simplicity. A dust case occurring for the night on 29-30 June 2019 at the Leipzig station is selected for that purpose (in particular, the dust intrusion as observed over Leipzig in June 2019 is widely characterized in Córdoba-Jabonero et al., 2021).

3 Results

3.1 Experimental overlap function \( F_{OVP} \)

P-MPL observations were carried out from 6 June to 26 July 2019 at the Leipzig station during the field campaign. Simultaneous P-MPL and Polly/MARTHA measurements as performed under relatively clean conditions were selected for estimating the OVP function. The first comparison analysis corresponded to 12 hourly-averaged P-MPL and Polly RCS profiles within the night-time period from 28 June 2019 at 18UT to 29 June 2019 at 05UT (day-time values on 28 June at 18UT: AOD=0.10, Ångstrom exponent AE=1.59). The second one was related to the MARTHA night-time RCS measurements as averaged for 4 hours from 23 July 2019 at 21UT to 24 July 2019 at 00UT (day-time values on 23 July at 18UT: AOD=0.09, AE=1.33); P-MPL RCS profiles were also averaged during that same period for comparison. Figure 1 shows the uncorrected by overlap P-MPL RCS profiles in comparison with the reference Polly (left panel) and MARTHA (right panel) ones for both those particular periods. The part of the P-MPL RCS profiling to be OVP-corrected is clearly highlighted ranging from the surface up to around 6 km height. Next, the experimental estimation of \( F_{OVP} \) for the P-MPL system is analysed in terms of the OVP-corrected RCS as
obtained by applying each of those experimentally-estimated $F_{OVP}^{Polly}$ and $F_{OVP}^{MARTHA}$ (see Sect. 2.3.1), including also a comparison with the original one, $F_{OVP}^{original}$ (as provided by the manufacturer).

Figure 1: Comparison of the normalized (left) reference Polly (red line; for clarity, the 12 P-MPL and Polly RCS profiles, from 28 June 18UT to 29 June 05UT, were averaged) and (right) MARTHA (blue line; 4 P-MPL and MARTHA RCS profiles, from 23 July 21UT to 24 July 00UT, were averaged) w.r.t. the uncorrected by overlap P-MPL profiles (black lines). Normalization height at 9.5 km a.g.l. The aerosol-free background signal is shown by a grey dashed line.

Figure 2 shows the experimental OVP functions, $F_{OVP}(z)$, as obtained from the comparison of the P-MPL RCS profiles w.r.t. Polly and MARTHA lidar measurements (top panel, $F_{OVP}^{Polly}$ in red, and $F_{OVP}^{MARTHA}$ in blue) (see Eq. 4) together with $F_{OVP}^{original}$; associated errors are also shown in the bottom panel. In addition, as both those OVP functions were obtained in two different days, temperature-related changes could be produced in the OVP estimation. Hence, the averaged $F_{OVP}^{SR}(z)$ between both OVP functions is also calculated, and shown together the absolute and relative errors in Fig. 2, top and bottom panels, respectively). Details on the OVP error processing are described in Annex A. By comparing with the original OVP function, large discrepancies can be clearly observed, highlighting the change of $F_{OVP}(z)$ with time, mostly in the relevant 1-5 km height-range. Regarding the OVP functions $F_{OVP}^{Polly}$ and $F_{OVP}^{MARTHA}$, differences are also found, mostly in the near-field range up to around 3 km height. However, by using $F_{OVP}^{SR}(z)$ instead of one of two others for P-MPL RCS correction, its relative error is just 14 ± 5% in average from 0.3 up to 10 km height (see Fig. 2-bottom). Taking into account these errors, $F_{OVP}^{SR}(z)$ can be the OVP function used for correcting the P-MPL RCS profiles at near-field heights, following the expression in Eq. 3, as it seems to be the best proxy for OVP correction of the P-MPL RCS profiles.
Figure 2: (Top) Experimental overlap functions, $F_{OVP}$, as obtained for two different days from the ratio between the P-MPL RCS profiles w.r.t. the Polly ($F_{OVP}^{Polly}$, red) and MARTHA ($F_{OVP}^{MARTHA}$, blue) ones, together with the averaged function ($F_{OVP}^{avg}$) of both of them (black line); the original overlap function as provided by the manufacturer, $F_{OVP}^{original}$, is also included (cyan line). (Bottom) Errors, $\Delta F_{OVP}$, associated to the OVP-function estimation for each comparison case: P-MPL w.r.t. Polly (red), P-MPL w.r.t. MARTHA (blue), and the averaged OVP function of both of them (black); the error for $F_{OVP}^{original}$ (cyan) and the relative error for $F_{OVP}^{avg}$ (green line) are also included.

The previous uncorrected and OVP-corrected P-MPL RCS profiles by using both $F_{OVP}^{avg}$ and $F_{OVP}^{original}$ are shown in Figure 3. Slightly differences are observed for the P-MPL RCS profiles as compared to those Polly and MARTHA ones by using $F_{OVP}^{avg}$, despite it was calculated from averaging $F_{OVP}^{Polly}$ and $F_{OVP}^{MARTHA}$, which were obtained from measurements on different days (only almost one month between them). Large differences are clearly found when $F_{OVP}^{original}$ is applied, mostly between 1.5 and 3 km height, evidencing that the OVP function as provided by the manufacturer is not applicable after some time for aerosol research, being necessary an regular OVP determination, as performed and described in this work. Once the P-MPL RCS profiles are OVP-corrected, the optical properties of the aerosols can be retrieved using inversion algorithms. OVP-induced effects in the inversion of the aerosol optical properties are analysed in Sect. 3.3.
Figure 3: OVP-corrected (black thick lines) P-MPL RCS profiles by using $F_{OVP}$ function and the uncorrected RCS ones (black thin lines), w.r.t. (Left) Polly (red line) and (Right) MARTHA (blue line) RCS profiles, together with the OVP-corrected ones by $F_{OVP}^{original}$ (cyan lines).

3.2 Volume linear depolarization ratio (VLDR)

Before analysing the OVP impact in the retrieval of the aerosol optical properties, the VLDR is also examined. As stated before, dDespite the VLDR is unaffected by the OVP correction, it actually affects, together with the PBC, $\beta_p$, the PLDR, $\delta_p$, estimation (see Sect. 2.43.2).

The P-MPL VLDR is calculated using Eq. 67 and compared with that derived from Polly measurements as reference, since TROPOS follows all quality assurance efforts regarding polarization lidar calibration tests in the Polly systems as recommended by EARLINET (Freundenthaler et al., 2008, 2016). A dust outbreak case observed at Leipzig site for the night on 29-30 June 2019 is examined for that purpose. Figure 4 shows the VLDR as obtained from both the $\delta_V^{MPL}$ and $\delta_V^{Polly}$ profiles as averaged from 18 to 23 UT on 29 June and from 00 to 05 UT on 30 June (for clarity, only averaged $\delta_V^P$ profiles are shown). The dust signature is clearly marked, showing a dust layer clearly confined between 3 and 6 km height, with a higher variability for the second interval due to the decay of dusty conditions at the end of that period, as reflected by a larger error uncertainty in time averaging. In overall, despite $\delta_V^{MPL}$ values seems to be higher than those $\delta_V^{Polly}$, peaking between 0.11 and 0.14 in the dust layer, they are within the error range. Hence, the VLDR was averaged within several aerosol-free height-intervals, below and above that defined dust layer, to analyse potential changes and offsets. Those mean $\delta_V^P$ values (and their standard deviation, SD) are shown in Table 2.

Table 2: Mean VLDR values together their standard deviation (SD) (and their relative SD error, in %) as obtained from the P-MPL and Polly measurements ($\delta_V^{MPL}$ and $\delta_V^{Polly}$ profiles) for aerosol-free height-intervals on 29-30 June 2019.
Height intervals (km) | $\delta^V$, mean ± SD (%SD) | P-MPL | Polly
--- | --- | --- | ---
1.5-2.5 | 0.0096 ± 0.0016 (16.6) | 0.0057 ± 0.0002 (3.4) | 
7.0-8.0 | 0.0088 ± 0.0010 (10.8) | 0.0057 ± 0.0037 (65.9) | 
8.0-9.0 | 0.0083 ± 0.0016 (19.7) | 0.003 ± 0.016 (>100) | 
Height-averaged | 0.0089 ± 0.0005 (6.0) | 0.0049 ± 0.0011 (23.1) | 

Looking at the results, $\delta^V_{\text{Polly}}$ presents larger errors than those for $\delta^V_{\text{MPL}}$, as associated to a lower signal-to-noise ratio as height increases for the Polly measurements (no smoothing applied). This is reflected by the higher relative error (%SD) found for the Polly VLDR (23%) w.r.t. to that for the P-MPL (6%) when all the aerosol-free height-intervals are considered, being the mean $\delta^V$ values of 0.0089 ± 0.0005 (%SD: 6%) and 0.0049 ± 0.0011 (%SD: 23%), respectively, for the P-MPL and Polly VLDR. As a result, a constant offset, $\Delta = \delta^V_{\text{Polly}} - \delta^V_{\text{MPL}}$, can be assumed between $\delta^V_{\text{MPL}}$ and $\delta^V_{\text{Polly}}$, obtaining $\Delta = -0.0040 ± 0.0016$. This offset can represent a correction to account for any slight mismatch in the transmitter and detector polarization planes and any impurity of the laser polarization state (Sassen, 2005), as also found in Córdoba-Jabonero et al. (2013) by characterizing the VLDR of a relatively older version (MPL-4) of the polarized MPL systems. Therefore, the P-MPL VLDR must be also corrected by that offset using the expression:

$$
\delta^V_{\text{MPL}}^{\text{corr}} = \delta^V_{\text{MPL}} + \Delta,
$$

where $\delta^V_{\text{MPL}}^{\text{corr}}$ is the corrected P-MPL VLDR profile, and $\delta^V_{\text{MPL}}$ is that VLDR as obtained from Eq. 2.

3.3 Particle backscatter coefficient (PBC) and particle linear depolarization ratio (PLDR)

The effect of the OVP correction on the P-MPL RCS is also analysed regarding the retrieval of the KF-derived $\beta_p$ profiles, as obtained by applying both $F_{\text{OVP}}^{\text{original}}$ and $F_{\text{OVP}}^{\text{avg}}$ to the RCS. A dust event as observed at Leipzig on the night from 29 to 30 June 2019 (the same dust case as previously exposed in Sect. 3.2) is selected for that purpose. In addition, both PLDR, $\delta_p$ (see Eq. 5), and VLDR, $\delta^V$ (see Eqs. 6 and 7, $\Delta$ offset corrected) are estimated. The OVP-induced effect is illustrated, in particular, using the vertical hourly-averaged profiling observed on 29 June 2019 at 20-21 UT, corresponding to a well-separated two-layer dust case (dust optical depth of 0.061). Figures 5 and 6 show the vertical profiles of $\beta_p$ and $\delta_p$ (and $\delta^V$), respectively, depending on the $F_{\text{OVP}}$ applied, as retrieved from the P-MPL measurements together to those derived from Polly ones for the selected case. Both P-MPL and Polly datasets show a dust layer clearly confined between around 3.5 and 5.0 km height. For comparison, in addition to the AOD-constrained KF solution for the PBC (reference height at 6.0 km, and reference backscatter coefficient of $10^{-7}$ Mm$^{-1}$ sr$^{-1}$) using $\sigma_a^{ref} = 43$ sr (that obtained from Polly elastic
measurements) (see Figs. 5a), $\beta_p$ is also retrieved by using the Raman-derived LR ($S^\text{Raman}_a = 60$ sr) for that dust layer as obtained from the night-time Polly Raman measurements (data not shown) (see Figs. 5b).

Table 3: Dust layer-averaged PBC, $\bar{\beta}_p$ (Mm$^{-1}$ sr$^{-1}$), and PLDR, $\bar{\delta}_p$, and the integrated backscatter, $B$ (10$^{-3}$ sr$^{-1}$), values, as obtained from P-MPL $\beta_p$ and $\delta_p$ profiles on 29 June 2019 at 20-21 UT in dependence of the $F_{OVP}$ applied for both the KF solutions (using $S^\text{eff}_a$ and $S^\text{Raman}_a$). Corresponding Polly values are also included.

| $F_{OVP}$       | $S^\text{eff}_a = 43$ sr | $S^\text{Raman}_a = 60$ sr | Polly       |
|-----------------|--------------------------|-----------------------------|-------------|
| $\bar{\beta}_p$| $B$                      | $\bar{\delta}_p$           | $\bar{\beta}_p$ | $B$ | $\bar{\delta}_p$ |
| $F_{OVP}$       | 0.93 ± 1.41 ± 0.32 ± 0.89 ± 1.35 ± 0.33 ± | 0.72 ± 1.08 ± 0.33 ± |
| $F_{Polly}$     | 0.92 ± 1.40 ± 0.32 ± 0.88 ± 1.33 ± 0.33 ± | 0.16 ± 0.01 ± 0.01 ± |
| $F_{\text{MARTHA}}$ | 0.94 ± 1.43 ± 0.32 ± 0.90 ± 1.36 ± 0.32 ± | 0.17 ± 0.10 ± 0.01 ± |
| $F_{\text{original}}$ | 0.87 ± 1.32 ± 0.33 ± 0.83 ± 1.26 ± 0.34 ± | 0.14 ± 0.05 ± 0.01 ± |

Regarding the dust layer, relatively small differences are found between Polly and P-MPL $\beta_p$ profiles (see Fig. 5), at least within error uncertainties. In order to assess those differences between both datasets, the layer-averaged PBC, $\bar{\beta}_p$ (Mm$^{-1}$ sr$^{-1}$), and the integrated backscatter, $B$ (sr$^{-1}$), for this 3.5-5.0-km dust layer were calculated to be used as a proxy of the degree of agreement. Derived $\bar{\beta}_p$ and $B$ values in dependence of $F_{OVP}$ for both the KF solutions (using either $S^\text{eff}_a$ or $S^\text{Raman}_a$) are shown in Table 3. In general, $\bar{\beta}_p$ and $B$ are higher for P-MPL w.r.t. Polly retrievals. Concerning the KF solutions for P-MPL profiles, a better agreement is achieved when the $S^\text{Raman}_a$ of 60 sr is applied (no AOD-constrain), i.e., lower differences for $\bar{\beta}_p$ and $B$ are found w.r.t. Polly-retrieved values.

Figure 5: Dust case as observed on 29 June 2019 at 20:00-21:00 UT over Leipzig: Vertical particle backscatter coefficient (PBC), $\beta_p$, as retrieved in dependence of the OVP function applied to the P-MPL RCS: $F_{OVP}$ w.r.t.
to Polly (red) and MARTHA (blue) data and both the $F_{OVP}^{\text{av}}$ (black) and $F_{OVP}^{\text{original}}$ (cyan) by using the KF solution with (a) the elastic AOD-constrained LR ($S_a^{\text{eff}} = 43$ sr), and (b) the Raman-retrieved LR ($S_a^{\text{Raman}} = 60$ sr) for the dust layer. Corresponding Polly-retrieved $\beta_p$ profiles are also included (green lines).

Nevertheless, the KF retrieval is mostly affected at near-field ranges (up to 3 km height) (see Fig. 5), as expected, since the OVP correction is rather relevant at those ranges. Negative $\beta_p$ values are predominantly found for the scenarios when the RCS is OVP-corrected by $F_{OVP}^{\text{Polly}}$ and $F_{OVP}^{\text{original}}$, being more pronounced when the $S_a^{\text{Raman}}$ is applied, since the LR to be applied in this height-interval must be closer to the elastic $S_a^{\text{eff}}$ of 43 sr. The best fitting seems to be achieved by using $F_{OVP}^{\text{MARTHA}}$ and $F_{OVP}^{\text{av}}$. Among those, however, results show that $\beta_p$ profiles are in a better agreement by using $F_{OVP}^{\text{av}}$ as compared to those Polly-derived $\beta_p$ at ranges from around 1 km down (see Fig. 5). Relative $\beta_p[F_{OVP}^{\text{av}}]$ errors of 10-20% are obtained.

Figure 6: The same as Fig. 5, but for the vertical particle linear depolarization ratio (PLDR), $\delta_p$, as retrieved from each $\beta_p[F_{OVP}]$ as shown in Fig. 5, and the VLDR, $\delta^V$ (grey line). The corresponding Polly-retrieved $\delta_p$ profile is also included (green line). For clarity, only error bars are marked for $\delta_p[F_{OVP}^{\text{av}}]$ (black) and $\delta_p^{\text{Polly}}$ (green).

By examining the PLDR profiles, the dust signature is also clearly marked between around 3.5 and 5.0 km height, i.e., typical $\delta_p$ values for dust of around 0.3 are found (see Table 3), indicating a predominance of coarse particles. No differences are found between Polly and P-MPL PLDR profiles for that layer (see Fig. 6), with mean $\delta_p$ values of 0.33±0.01 (Polly) and 0.32-0.34±0.02 (P-MPL, depending on the $F_{OVP}$ applied and the LR used) (see Table 3).

4 Conclusions

A comprehensive two-month field intercomparison campaign has been performed in summer 2019 to characterize the performance of a polarized Micro-Pulse Lidar (P-MPL) system, and to check the quality of the retrieved aerosol products. Atmospheric observations with of the P-MPL system have been examined
against those from two reference EARLINET lidars (Polly and MARTHA), which are operative at Leipzig site (Germany, 51.4°N 12.4°E, 125 m a.s.l.) as managed by TROPOS. In particular, an experimental assessment in terms of the overlap (OVP) correction and its impact in the retrieval of the aerosol optical properties has been achieved. Furthermore, the volume linear depolarization ratio (VLDR) has also been cross-checked and corrections applied, allowing an accurate retrieval. The aim of this work has been focused on the determination of the lidar-specific true OVP function and on investigating in detail the accuracy of both the retrieved particle backscatter coefficient (PBC) and particle linear depolarization ratio (PLDR) profiles.

It has been highlighted that the OVP function as delivered by the P-MPL manufacturer cannot be long used. The reasons are manifold, but an experimental assessment suitable estimation of the OVP function determination should be recommended for the MPL systems. The experimental procedure to determine the OVP function for the P-MPL system has been described in the basis of the comparison to reference lidars. The optimal OVP function for correcting our the P-MPL measurements has been experimentally obtained, together with its uncertainties, under clean observational conditions from simultaneous P-MPL and Polly/MARTHA observations, and compared with the original one as provided by the manufacturer. In addition, depending on the OVP function applied, the OVP correction-induced effects on the retrieval of both the PBC and PLDR for the P-MPL system have been analysed for two KF solutions by using either the elastic (AOD-constrained) or the Raman-provided lidar ratios in comparison with those PBC and PLDR retrievals as obtained from simultaneous Polly observations. A dust case as observed at Leipzig is analyzed for that purpose.

Additionally, despite the VLDR is OVP-unaffected, it has been also examined in comparison with the Polly VLDR regarding its effect in the PLDR determination. A suitable VLDR profile has been usually obtained, being only needed to be corrected by a small offset value, which has been also estimated. Once P-MPL measurements were optimally OVP-corrected and the VLDR adjusted, both the PBC, and also the PLDR, profiles have been accurately derived by using the KF solution (an effective LR is obtained in constraint with AERONET AOD).

In overall, as a systematic requirement for lidar systems, an adequate OVP function determination and VLDR testing analysis is needed to be determined performed in a regular basis in order to correct the P-MPL measurements and, hence, to derive suitable aerosol products (backscatter, depolarization, extinction). The procedure described in this study can be useful to be applied to similar P-MPL systems that cannot regularly apply the established MPLNET calibrations. Moreover, such kind of efforts should be addressed on the way to combine all existing networks in Europe (EARLINET), Asia (AD-NET), Latina America (LALINET), and also MPLNET within the future vision of GAW (Global Atmospheric Watch) Aerosol Lidar Observations Network (GALION).

Annex A

The experimental overlap (OVP) function, \( F_{OVP}(z) \), is obtained from the expression

\[
F_{OVP}(z) = \frac{P_{MPL}(z)}{P_{ref}(z)}.
\]
where $P^{MPL}(z)$ are the P-MPL RCS profiles, which are compared against those reference lidar measurements, $P^{ref}(z)$ (ref denotes either Polly or MARTHA) using the experimental approach as described in this work.

The error associated to the determination of the OVP function, $\Delta F_{OVP}$, is obtained from error propagation calculations of the Eq. A.1. In this sense, it can be expressed as ($z$-dependence is omitted for simplicity, hereafter)

$$\Delta F_{OVP}^{ref} = F_{OVP}^{ref} \times \left[ \frac{\Delta P^{MPL}}{P^{MPL}} + \frac{\Delta P^{ref}}{P^{ref}} \right],$$  

(A.2)

where $\Delta P^{MPL}$ and $\Delta P^{ref}$ are, respectively, the errors related to $P^{MPL}$ and $P^{ref}$.

$\Delta P^{MPL}$ can be estimated as composed of two error contributions: one associated to instrumental corrections (energy fluctuations, instrumental calibrations, solar background, ...), $\varepsilon^{MPL}$, as described in Welton and Campbell (2002), and another one reflecting the atmospheric variability within the time-averaging performed of the $P^{MPL}$ profiles, which is expressed by the standard deviation, $sd^{MPL}$; hence, it can be obtained from the expression

$$\Delta P^{MPL} = \sqrt{(\varepsilon^{MPL})^2 + (sd^{MPL})^2}. $$  

(A.3)

Errors associated to the reference lidar measurements, $\Delta P^{ref}$ (ref is for either Polly or MARTHA), are represented by the standard deviation, as obtained from the corresponding time-averaging of $P^{ref}$ profiles.

In this work, the averaged function between $F_{OVP}^{Polly}$ and $F_{OVP}^{MARTHA}$ is also calculated, i.e.,

$$F_{OVP}^{av} = \frac{F_{OVP}^{Polly} + F_{OVP}^{MARTHA}}{2},$$  

(A.4)

being the error related to this function, $\Delta F_{OVP}^{av}$, estimated as

$$\Delta F_{OVP}^{av} = \sqrt{\left( \frac{\Delta F_{OVP}^{Polly}}{2} \right)^2 + \left( \frac{\Delta F_{OVP}^{MARTHA}}{2} \right)^2},$$  

(A.5)

where $\Delta F_{OVP}^{ref}$ (ref denotes either Polly or MARTHA) is the error as obtained from Eq. A.2.

**Data availability.** All data generated and analysed for this study are available from the authors upon reasonable request.

**Author Contributions.** CC-J and AA designed the study and wrote the original draft paper. CC-J, AA, CJ and HB provided data. CC-J and CJ performed data analysis with contributions from AA, HB, M-AL-C and RE. All authors reviewed and edited the final version of the manuscript. All the authors agreed to the final version of the paper.

**Competing interests.** The authors declare that they have no conflict of interest.
