Abstract

4-Hydroxynonenal (HNE) is an important product of plasma membrane lipid peroxidation, which is a cause of cell and tissue injury. Mitochondrial DNA (mtDNA)-depleted \( \rho^0 \) cells were established using human cervical cancer and oral squamous cell carcinoma cell lines. We investigated the effect of reactive oxygen species in \( \rho^0 \) cells, especially the mechanism of hydrogen peroxide (H\(_2\)O\(_2\))-mediated cell death. These cell were subjected to high oxidative stress and, compared with their parental cells, showed greater sensitivity to H\(_2\)O\(_2\) and high lipid peroxidation. Upregulation of HNE in the plasma membrane was observed prior to the increase in intracellular H\(_2\)O\(_2\). The amount of oxidized lipid present changed H\(_2\)O\(_2\) permeability and administration of oxidized lipid led to further cell death after treatment with H\(_2\)O\(_2\). Expression levels of lipoxygenase ALOX genes (ie ALOX5, ALOX12, and ALOX15) were upregulated in \( \rho^0 \) cells, as were expression levels of ALOX12 and ALOX15 proteins. ALOX5 protein was mainly distributed in the nucleus, while ALOX12 and ALOX15 proteins were distributed in the nucleus and the cytoplasm. Although expression of COX2 gene was upregulated, its protein expression did not increase. ALOX (especially ALOX15) may be involved in the sensitivity of cancer cells to treatment. These data offer promise for the development of novel anticancer agents by altering the oxidation state of the plasma membrane. Our results showed that lipid peroxidation status is important for H\(_2\)O\(_2\) sensitivity and that ALOX15 is involved in lipid peroxidation status.

KEYWORDS

cell membrane, hydrogen peroxide, lipid peroxidation, mitochondria, oxidative stress

Abbreviations: \( \bullet \) OH, hydroxyl radical; ALOX, lipoxygenase; COX, cyclooxygenase; DOPC, 1,2-dioleoyl-sn-glycero-3-phosphocholine; H\(_2\)O\(_2\), hydrogen peroxide; HNE, 4-Hydroxynonenal; HFP, Hydroxypyrenyl fluorescein; MIC, microscope observation; NDGA, nordihydroguaiaretic acid; PINK1, PTEN-induced kinase 1; POVPc, 1-palmitoyl-2-(5’-oxo-valeroyl)-sn-glycero-3-phosphocholine; ROS, Reactive oxygen species; RT, radiation therapy.

1 | INTRODUCTION

ROS are defined as chemically reactive species containing oxygen, some of which are peroxidases or hydroxyl radicals. ROS production is effective in the chemotherapy and RT of cancer.\(^1\)\(^-\)\(^3\) Numerous chemicals can produce ROS than affect cancer cells\(^4\)\(^-\)\(^8\) and some of these are under investigation in clinical trials.\(^9\) Some ROS, for example H\(_2\)O\(_2\), are used as sensitizers of cancer cells by producing reactive oxygen during RT.\(^1\)\(^0\)\(^-\)\(^1\)\(^1\) Similarly, ROS are produced by nicotinamide adenine dinucleotide phosphate (NADPH) oxidase in the cytoplasm.\(^1\)\(^2\) However, the main source of ROS may be the mitochondrial electron transport chain through oxidative phosphorylation.\(^1\)\(^3\)\(^-\)\(^1\)\(^4\) Mitochondrial DNA (mtDNA) encodes 13 proteins that are components of the mitochondrial electron transport chain. Damage to mtDNA results in increased production of ROS, conversely causing neurodegenerative diseases and various types of cancer.\(^1\)\(^5\)\(^-\)\(^1\)\(^6\) Therefore, these mtDNA-damaged cells may be valuable models for studying ROS-related disease. Mitochondrial DNA devoid of H\(^0\) cells were established from a human cervical cancer cell line (HeLa) and from an oral squamous cell carcinoma (SAS). These H\(^0\) cells were sensitive to ROS, in particular H\(_2\)O\(_2\).\(^1\)\(^7\) Notably, yeast H\(^0\) cells have also shown sensitivity to treatment with H\(_2\)O\(_2\).\(^1\)\(^8\) Recently, H\(^0\) cells from osteosarcoma and lung carcinoma have shown sensitivity to X-ray irradiation related to oxidative stress.\(^1\)\(^9\) Conversely, there are several studies reporting that H\(^0\) cells are resistant to oxidative stress, especially to radiation. H\(^0\) cells from human fibroblasts have shown resistance to \(\gamma\)-irradiation by decreasing apoptosis.\(^2\)\(^0\) In addition, H\(^0\) cells from the human pancreatic tumor MiaPaCa-2 cell line showed resistance to X-ray irradiation via activation of cyclin B1.\(^2\)\(^1\) Moreover, H\(^0\) cells from healthy human bronchial epithelial cells have shown resistance to oxidative stress. At present, the sensitivity or resistance of H\(^0\) cells to oxidative stress and the stress response mechanism involved in these processes have not been fully elucidated.

ROS react with polyunsaturated fatty acids in the lipid membranes, inducing lipid peroxidation that leads to cell death. HNE, the end product of lipid peroxidation reacts with low-molecular-weight compounds (eg, glutathione, proteins, and DNA), and is considered a second messenger of lipid peroxidation. HNE induces lipid peroxidation that leads to cell death. HNE, the end product of lipid peroxidation reacts with low-molecular-weight compounds (eg, glutathione, proteins, and DNA), and is considered a second messenger of lipid peroxidation. HNE, the end product of lipid peroxidation reacts with low-molecular-weight compounds (eg, glutathione, proteins, and DNA), and is considered a second messenger of lipid peroxidation. Therefore, these mtDNA-damaged cells may be valuable models for studying ROS-related disease. Mitochondrial DNA devoid of H\(^0\) cells were established from a human cervical cancer cell line (HeLa) and from an oral squamous cell carcinoma (SAS). These H\(^0\) cells were sensitive to ROS, in particular H\(_2\)O\(_2\).\(^1\)\(^7\) Notably, yeast H\(^0\) cells have also shown sensitivity to treatment with H\(_2\)O\(_2\).\(^1\)\(^8\) Recently, H\(^0\) cells from osteosarcoma and lung carcinoma have shown sensitivity to X-ray irradiation related to oxidative stress.\(^1\)\(^9\) Conversely, there are several studies reporting that H\(^0\) cells are resistant to oxidative stress, especially to radiation. H\(^0\) cells from human fibroblasts have shown resistance to \(\gamma\)-irradiation by decreasing apoptosis.\(^2\)\(^0\) In addition, H\(^0\) cells from the human pancreatic tumor MiaPaCa-2 cell line showed resistance to X-ray irradiation via activation of cyclin B1.\(^2\)\(^1\) Moreover, H\(^0\) cells from healthy human bronchial epithelial cells have shown resistance to oxidative stress. At present, the sensitivity or resistance of H\(^0\) cells to oxidative stress and the stress response mechanism involved in these processes have not been fully elucidated.

2 | MATERIALS AND METHODS

2.1 | Cell culture

Human cancer cell lines HeLa and SAS were obtained from the Cell Resource Center for Biomedical Research, Institute of Development, Aging and Cancer, Tohoku University (Sendai, Japan). H\(^0\) cells were established through culture in RPMI1640 (Wako Pure Chemical Industries Ltd., Osaka, Japan) containing 5% FBS (Gibco Invitrogen Corp., Carlsbad, CA, USA), 50 ng/mL etidium bromide (Nacalai Tesque Inc., Kyoto, Japan), 50 \(\mu\)g/mL uridine (Sigma-Aldrich, St Louis, MO, USA), and 110 \(\mu\)g/mL sodium pyruvate (Sigma-Aldrich) for 3-4 wk.\(^1\)\(^7\) Cells were maintained in RPMI 1640 supplemented with 10% FBS, 50 \(\mu\)g/mL uridine, and 110 \(\mu\)g/mL sodium pyruvate in a humidified atmosphere at 37°C with 5% carbon dioxide. Exponentially growing cells were used in all experiments.

2.2 | Relative levels of internal H\(_2\)O\(_2\)

Internal H\(_2\)O\(_2\) was visualized using HYDROP™ (Goryo Chemical Inc., Hokkaido, Japan) as previously described.\(^1\)\(^7\) Briefly, cells in glass-bottomed dishes (Matsunami Glass Ind., Ltd., Osaka, Japan) were cultured in RPMI 1640 with or without 50 \(\mu\)mol/L H\(_2\)O\(_2\) for 10 min, 30 min, 1 h, and 2 h. The cultured cells were washed with noncontaining H\(_2\)O\(_2\) RPMI 1640 twice to remove the H\(_2\)O\(_2\) from the medium, and subjected to treatment with 2.5 \(\mu\)mol/L HYDROP™ in RPMI 1640 at 37°C for 20 min. Subsequently, the cells were washed with RPMI 1640 twice, and fluorescence images were obtained using a BZ-8000 fluorescence microscope (Keyence Corporation, Osaka, Japan). The ImageJ software (Rasband, W.S., Image). U.S. National Institutes of Health, Bethesda, Maryland, USA, http://rsb.info.nih.gov/ij/ 1997-2012) was used to measure fluorescence intensity.

2.3 | Intracellular intake of H\(_2\)O\(_2\) using a stable isotope

A H\(_2\)O\(_2\)\(^{18}\)O\(_2\) solution (Sigma-Aldrich) was used to measure the intracellular intake of H\(_2\)O\(_2\). Cells were subjected to treatment with 50 \(\mu\)mol/L H\(_2\)O\(_2\)\(^{18}\)O\(_2\) solution for 1 h. After treatment, the cells were washed with phosphate-buffered saline (PBS) three times. Following the wash, the cells were collected and dried using an FDU-2200 freeze dryer (Tokyo Rikakikai Co. Ltd., Tokyo, Japan) for 3 h. Dried samples were sent for analysis to Taiyo Nippon Sanso Corporation (Tokyo, Japan). The levels of \(^{18}\)O\(_2\) in treated cells were measured using stable isotope-ratio mass spectrometry. The results are shown as delta \(\%\) compared with the standard mean ocean water (SMOW \%).

2.4 | Immunofluorescence

Cells were cultured in glass-bottomed dishes using RPMI 1640 with or without 50 \(\mu\)mol/L H\(_2\)O\(_2\) for 1 and 2 h. Subsequently, the cells were fixed with 4% formaldehyde in PBS for 30 min, and rinsed three times with PBS. Plasma membranes were permeabilized by incubation in 95% ethanol with 5% acetic acid for 10 min. After washing five times with PBS, cells were incubated for 30 min in blocking solution (5% skimmed milk in PBS-T; PBS with 0.05% Tween 20). The primary antibodies (incubated at 4°C overnight) were mouse anti-HNE (1:200 dilution; Japan institute for the control of aging, Shizuoka, Japan),...
POVPC and H$_2$O$_2$ kit (Dojindo Molecular Technologies, Inc., Kumamoto, Japan), as producing blue luminescence. Through the liposome membrane resulted in luminol reaction, producing blue luminescence.

Step One Plus (Applied Biosystems; Foster City, CA, USA) using Quantitative PCR (qPCR). The reactions were performed with one cycle of denaturation (95°C for 10 min) was performed, followed by 40 cycles of amplification (95°C for 10 s and 60°C for 60 s). Each experiment was performed in triplicate. Table 1 lists the primer sequences used in this experiment.

### 2.8 | Western blotting

Each cell lysate (30 μg per lane) was subjected to SDS-PAGE under reduced conditions using a 10% or 15% polyacrylamide gel. The proteins were subsequently blotted onto a PVDF membrane. After blocking with blocking buffer (3% skimmed milk in TBS-T; TBS with 0.05% Tween 20, for ALOX12 antibody and 5% skimmed milk in PBS-T for the other primary antibodies), the blotted membranes were incubated with primary antibodies (rabbit anti-AOX5, anti-AOX12, anti-AOX15, mouse anti-COX1, rabbit anti-COX2; Abcam: ab169755, ab211506, ab80221, ab695, and ab15191, rabbit anti-Akt, pAkt$^{T308}$, pAkt$^{S473}$, FOXO1, pGSK3β$^\text{S473}$, Cell Signaling Technology, Danvers, MA, USA: #4691, #13038, #4060, #2880, #5558, mouse anti-BCL2, Bax; Santa Cruz Biotechnology, San Diego, CA, USA: SC-7382, SC-7480) in blocking buffer over-night. After five washes with TBS-T (ALOX12 antibody) or PBS-T (other antibodies), the membranes were incubated with peroxidase-conjugated anti-rabbit IgG antibody or anti-mouse IgG antibodies (GE Healthcare UK Ltd., Amersham Place, England) at room temperature for 2 h. Immunoreactive proteins were visualized with ECL prime (GE Healthcare) using ChemiDoc XRS Plus (BIO-RAD Laboratories, Inc., Hercules, CA, USA). An anti-β-actin antibody (Novus Biologicals LLC, Centennial, CO, USA; NB100-56874) was used as loading control. The dilution factor for all antibodies was 1:1000. Table 2 represents the mean and standard error of the mean (SEM) of three independent $\mu^\text{0}$/parent intensity ratios after normalization against β-actin.

### 2.9 | ALOX inhibitor assay

Cells were treated with 10 μmol/L caffeic acid (Nacalai Tesque Inc.), the AOX5 inhibitor, or 10 μmol/L NDGA (Sigma-Aldrich), the

### 2.5 | Liposome assay

Liposomes containing luminol and horseradish peroxidase (HRP) were prepared as follows: DOPC (Avanti Polar Lipids Inc., Alabaster, AL, USA) and POVPC (Avanti Polar Lipids Inc.) were dissolved in chloroform (1 mg/mL) and mixed together. The dissolved lipids were dried to remove the chloroform. Subsequently, the mixture was added to 50 mmol/L Tris-HCl (pH 8.6) buffer containing 10 mmol/L luminol (Nacalai Tesque Inc.: 20751-34) and 100 μmol/L HRP (Wako Pure Chemical Industries Ltd.: 169-10791) and was then sonicated. The diameter of the prepared liposomes was calculated via the Dynamic Light Scattering method using ELS-Z2M (Otsuka Electronics Co. Ltd., Osaka, Japan). Subsequently, 8.8 mmol/L H$_2$O$_2$ were administered to the liposomes, and luminescence was observed using a luminometer (JASCO, Tokyo, Japan: FP-6300). Passage of H$_2$O$_2$ through the liposome membrane resulted in luminol reaction, producing blue luminescence.

### 2.6 | Administration of oxidized lipid

POVPC (12.5-50 μmol/L) was administered to the cultured medium using the ethanol injection method.$^{27,28}$ This lipid has been shown to localize to the plasma membrane.$^{27,28}$ After 10 min (SAS) or 30 min (HeLa) of treatment, POVPC was removed, and the cells were treated with 25 μmol/L H$_2$O$_2$ for 48 h. After administration of POVPC and H$_2$O$_2$, cell survival was analyzed using the CCK-8 assay kit (Dojindo Molecular Technologies, Inc., Kumamoto, Japan), as previously described.$^{17}$

### 2.7 | Quantitative PCR

Total RNA was extracted using ISOGEN (Nippon Gene, Toyama, Japan), and reverse transcription was performed as previously described.$^{17}$ cDNA equivalent to 1 ng of total RNA was used for the Quantitative PCR (qPCR). The reactions were performed with Step One Plus (Applied Biosystems; Foster City, CA, USA) using THUNDERBIRD® qPCR Mix (TOYOBO, Osaka, Japan). β-actin was used as the loading control. For the amplification of genes, one cycle of denaturation (95°C for 10 min) was performed, followed by 40 cycles of amplification (95°C for 10 s and 60°C for 60 s). Each experiment was performed in triplicate. Table 1 lists the primer sequences used in this experiment.

nonspecific ALOXs inhibitor, at 37°C for 10 min. After removal of the inhibitor-containing medium, the cells were treated with 50 µmol/L H_2O_2 for 1 h. HYDROP™ and HNE antibody were used as described above to detect internal H_2O_2 or HNE.

2.10 | Detection of OH using HPF

Internal levels of ·OH were detected using HPF (Goryo Chemical Inc.) according to the protocol provided by the manufacturer with slight modification. HPF (10 µmol/L) with MIC buffer (130 mmol/L sodium chloride, 5.3 mmol/L potassium chloride, 0.8 mmol/L magnesium sulfate, 1 mmol/L disodium phosphate, 2 mmol/L glucose, 20 mmol/L HEPES, 1 mmol/L sodium pyruvate, 2.5 mmol/L sodium bicarbonate, 1 mmol/L ascorbic acid, 1.5 mmol/L calcium chloride, and 1.5 mg/mL bovine serum albumin (BSA)) was added to the cells in glass-bottomed dishes. After incubation at 37°C for 15 min, the HPF with MIC buffer was replaced with new MIC buffer. Images were obtained using a BZ-8000 fluorescence microscope. Nuclei were counterstained with DAPI as described above.

2.11 | Statistical analysis

One-way analysis of variance with Scheffe’s F test was performed for the water-soluble tetrazolium assay and ALOX inhibitor experiment. All other statistical analyses were performed using Student’s t test. A P < .05 denoted statistical significance. The results were expressed as means ± SEM.

3 | RESULTS

3.1 | Relative levels of internal H_2O_2 and intake of H_2O_2

After treatment for 1 h, the internal levels of H_2O_2 were increased only in ρ^0 vs parental cells (Figure 1A). The results obtained from the treatment with 18O_2-labeled H_2O_2 showed that the intake of H_2O_2 in ρ^0 cells was significantly higher than that observed in parental cells after treatment with H_2O_2 for 1 h (Figure 1B).

3.2 | Timing of increase in lipid peroxidation and internal levels of H_2O_2

Significantly higher intensity was observed in ρ^0 cells (Figure 2A, B). Co-staining with PINK1 (localized in mitochondria) and aquaporin 11 (localized in the plasma membrane) revealed that HNE was mainly localized in the plasma membrane (Figure 2C, D). Moreover, temporal change of lipid peroxidation was observed to investigate the timing of this process after treatment with H_2O_2 (Figure 2E). Lipid peroxidation was increased 1 h after treatment (Figure 2E, F), whereas the internal levels of H_2O_2 were increased in parental cells 2 h after treatment (Figure 2F).

3.3 | H_2O_2 permeability using liposome and administration of oxidized lipid

We prepared liposomes encapsulating luminol and HRP to quantify the permeation of H_2O_2. Representative phospholipids of the plasma membrane (ie, DOPC and oxidized lipid POVPC) were used in this model. Internal levels of H_2O_2 can be detected as luminescence of luminol catalyzed by HRP (Figure 3A). The intensity of luminescence was increased following the administration of H_2O_2. Differential DOPC/POVPC ratio liposomes were prepared to investigate
changes in H$_2$O$_2$ permeability. Maximum H$_2$O$_2$ transport appeared in the presence of several (2-4) mol% of POVPC (Figure 3B). The POVPC administration experiment was conducted to confirm whether administration of this oxidized lipid led to cell death. The results showed that the administration of 12.5 μmol/L POVPC significantly increased the sensitivity of HeLa and SAS parental cells to
H$_2$O$_2$. However, a higher concentration of POVPC did not induce a similar increase in sensitivity to H$_2$O$_2$ (Figure 3C). Furthermore, administration of different concentrations of POVPC revealed that the relationship between cell viability and POVPC concentration did not show a linear concentration-dependent pattern. However, it showed a reverse bell shape, with the lowest viability in HeLa and SAS parental (C) or $\rho^0$ (D) cells before H$_2$O$_2$ treatment. The numbers in parentheses represent the concentration of POVPC (μmol/L). E, F, Effect of the concentration of POVPC on the viability of HeLa and SAS parental (E) or $\rho^0$ (F) cells before H$_2$O$_2$ treatment (25 μmol/L). The results are expressed as the mean ± SEM. *$P < .05$, **$P < .01$ using Scheffe’s F test (vs control), *$P < .05$, **$P < .01$ using Scheffe’s F test (vs treatment with H$_2$O$_2$). C: control, P: treatment with POVPC (12.5 μmol/L), H: treatment with H$_2$O$_2$ (25 μmol/L for 48 h), P+H: treatment with H$_2$O$_2$ after treatment with POVPC.

3.4 | Gene expression and protein expression of ALOX

Gene expression of ALOX5, ALOX12, and ALOX15 – involved in lipid peroxidation of the plasma membrane – was upregulated in $\rho^0$ cells (Figure 4A: ALOX5, 4B: ALOX12, and 4C: ALOX15). In addition, protein expression of ALOX12 and ALOX15, unlike that of ALOX5, was upregulated in both HeLa and SAS $\rho^0$ cells (Figure 4D and Table 2). Investigation of spatial distribution showed that the ALOX12 and ALOX15 proteins were distributed in the nucleus and cytoplasm. Conversely, the ALOX5 protein was distributed only in the nucleus (Figure S1). A semiquantitative analysis of immunofluorescence revealed that the relative expression of the ALOX12 and ALOX15 proteins was upregulated in $\rho^0$ cells (Figure 5A, C: ALOX12, Figure 5B, D: ALOX15).

3.5 | Inhibition of ALOX

Treatment with 10 μmol/L caffeic acid (ALOX-5 inhibitor) or 10 μmol/L NDGA (universal ALOX inhibitor) was performed before treatment with H$_2$O$_2$ to investigate the effect of ALOX on the levels of internal H$_2$O$_2$ or HNE. The results showed that, unlike caffeic acid, NDGA significantly inhibited the levels of internal H$_2$O$_2$ and lipid peroxidation (Figure 6).

3.6 | Gene and protein expressions of COX

Expression of the COX1 gene was downregulated in SAS $\rho^0$ cells (Figure 7A). Conversely, expression of the COX2 gene was significantly upregulated in HeLa and SAS $\rho^0$ cells (Figure 7B). Protein expression of COX1 did not change significantly between parental and $\rho^0$ cells, whereas that of COX2 was downregulated in $\rho^0$ cells (Figure 7C and Table 2). Immunofluorescence of COX revealed that COX1 was mainly localized in the nucleus, whereas COX2 was mainly localized in the cytoplasm (Figure 7D).
3.7 | Phosphorylation of Akt and protein expressions involved in apoptosis

Phosphorylation of Akt, which inhibits apoptosis and regulates cell proliferation, was investigated using western blotting. This analysis revealed a marked decrease in Akt phosphorylation in \( \rho^0 \) cells (Figure 8 and Table 2). Expression of Akt downstream proteins was also investigated. Expression of FOXO1, which is downregulated by Akt phosphorylation and inhibited apoptosis, was increased. Moreover, pGSK3β\(^{S9} \), which is the inactivated form of GSK3β, was decreased in \( \rho^0 \) cells. Expression of the anti-apoptotic protein BCL2 was decreased, whereas expression of the apoptosis-inducing protein Bax was increased in \( \rho^0 \) cells (Figure 8 and Table 2).

4 | DISCUSSION

The present results indicated that the susceptibility of \( \rho^0 \) cells to \( \text{H}_2\text{O}_2 \) may be attributed to an increase in the levels of intracellular ROS due to peroxidation of the plasma membrane. \( \rho^0 \) cells from osteosarcomas have previously shown sensitivity to X-ray irradiation and produced more ROS from mitochondria than their parental cells.\(^{14,19} \) Similarly, lung carcinoma \( \rho^0 \) cells have shown sensitivity
Conversely, $\rho^0$ cells may be resistant to oxidative stress; and $\rho^0$ cells from GM701 and BEAS-2B have shown resistance to irradiation. Additionally, GM701 $\rho^0$ and BEAS-2B $\rho^0$ cells have shown resistance through inhibition of apoptosis and reduction of DNA damage, respectively. However, in these cell lines, intracellular levels of ROS were not determined. Therefore, it remained unknown whether $\rho^0$ cells exhibited resistance to ROS, such as $H_2O_2$. Collectively, the increased production of internal ROS via oxidative stress may lead to increased cell death in $\rho^0$ cells.

In our study, liposome membrane experiments showed that the content of oxidized lipid in liposomes increased $H_2O_2$ permeability by at least several (2-4) mol% (Figure 3A, B). Administration of oxidized lipid to HeLa and SAS parent cells produced a decrease in cell viability following treatment with $H_2O_2$ (Figure 3C, D). The reduced cell viability induced by 12.5 $\mu$mol/L POVPC may reflect the results of the liposome experiments. As shown in Figure 3B, the highest uptake of $H_2O_2$ was caused at a POVPC concentration of several (2-4) mol%, and administration of 12.5 $\mu$mol/L POVPC (Figure 3D) induced marked cell damage. In contrast, the administration of oxidized lipid did not affect cell viability following treatment with $H_2O_2$ in $\rho^0$ cells, in which lipid peroxidation was enhanced (Figure 3E, F). From these results, the concentration of the oxidized lipids was thought to influence $H_2O_2$ permeability and viability. However, administration of oxidized lipids to parental cells whose plasma membrane was not highly oxidized, is effective in inducing cell death after treatment with $H_2O_2$. Recently, it was reported that the density of phospholipids in the plasma membrane...
is involved in the efficiency of membrane permeability (i.e., uptake of ions or low-molecular-weight substances, such as H$_2$O$_2$). The results of our liposome experiment are in accordance with those findings reported by a recent study, suggesting that different densities of POVPC influence H$_2$O$_2$ membrane permeability. Uptake of H$_2$O$_2$ may be largely related to changes in the plasma membrane itself, rather than the presence of functional proteins on the membrane (i.e., aquaporins) that are involved in the permeation of H$_2$O$_2$ into the cell.

In HeLa and SAS $\rho^0$ cells, lipid peroxidation in the plasma membrane was higher than that observed in parental cells. The following three factors may be involved in lipid peroxidation and cell death: (a) downregulation of the antioxidant enzymes; (b) upregulation of the endogenous levels of ROS; and (c) upregulation of intracellular oxidase. It has been reported that catalase activity and expression of the Mn-SOD gene were upregulated in $\rho^0$ cells. In addition, expression of the GPx1 gene was downregulated in SAS $\rho^0$ cells, whereas it was upregulated in HeLa $\rho^0$ cells.

In osteosarcoma, rhabdomyosarcoma, and lung $\rho^0$ cells, glutathione peroxidase activity and the expression levels of the Mn-SOD and CuZn-SOD genes were upregulated. However, expression of the CuZn-SOD protein in osteosarcoma $\rho^0$ cells was downregulated. These results suggested that antioxidant enzymes are not the main factors involved in lipid peroxidation in $\rho^0$ cells. It has been reported that the levels of superoxide from the mitochondria are decreased in $\rho^0$ cells.

Moreover, it has been reported that the administration of HNE leads to increased levels of internal ROS using 2,7′-dichlorodihydrofluorescein diacetate in parental cells. However, the levels of internal ROS in $\rho^0$ cells did not increase significantly. Our data showed that the levels of HNE and ·OH were increased in $\rho^0$ cells (Figures 2 and S2). Currently, the involvement of mitochondria-derived ROS in lipid peroxidation of the plasma membrane in $\rho^0$ cells remains unknown.

It has been reported that an increase in ·OH from the mitochondria was detected in osteosarcoma $\rho^0$ cells.

**FIGURE 7** Gene and protein expression of COX. A, Relative gene expression of COX1. B, Relative gene expression of COX2. C, Western blotting of COX1 and COX2. D, Spatial distribution of COX1 (green) and COX2 (red) in SAS parent cells. The results are expressed as the mean ± SEM. *P < .05, **P < .01 using Student's t test.

**FIGURE 8** Downregulation of Akt phosphorylation and promotion of apoptosis signaling in $\rho^0$ cells. Western blots of Akt, pAkt$^{T308}$, pAkt$^{S473}$, FOXO1, pGSK3β$^S9$, BCL2, Bax, and β-actin are shown. Downregulation of Akt phosphorylation was observed in both HeLa and SAS $\rho^0$ cells. The expression of apoptosis-promoting proteins (FOXO1 and Bax) was upregulated, whereas that of apoptosis-inhibiting proteins (pGSK3β$^S9$ and BCL2) was downregulated.
The expression of ALOX12 and ALOX15 (mRNA and protein levels) and COX2 was upregulated in $\rho^0$ cells (Figure 4-7). ALOX15 produces 13-hydroxyoctadecadienoic acid, which is a precursor of HNE from linoleic acid.\(^{39}\) Inhibition of ALOX 12 and 15, unlike ALOX5, resulted in the downregulation of HNE and $H_2O_2$ permeability in $\rho^0$ cells (Figure 6). Moreover, overexpression of ALOX15 enhanced erastin and RAS-selective lethal compound 3-induced ferroptosis, an iron-dependent cell death via activation of the HNE.\(^{40}\) Furthermore, LOX15 reportedly plays a central role in the initiation and execution of ferroptosis.\(^{41}\) These results suggested that the expression of internal oxidative enzymes is more important than that of antioxidative enzymes for lipid oxidation in $\rho^0$ cells. Additionally, ALOX15 plays an important role in the peroxidation of the plasma membrane in $\rho^0$ cells. To date, there is no evidence showing that COX2 directly peroxidizes lipids and produces HNE. However, it has been reported that HNE induces the expression of the COX2 gene, and that this expression is stabilized by the p38 mitogen-activated protein kinase.\(^{42}\) In addition, COX2 has been reported to be involved in PI3K/Akt signaling.\(^{43}\) Recently, it was reported that administration of HNE decreased Akt phosphorylation and induced apoptosis in an osteosarcoma cell line.\(^{44}\) These findings indicated a strong relationship between lipid peroxidation and intracellular signal pathways (eg, Akt signaling). It has been shown that phosphorylation of Akt was downregulated in HeLa $\rho^0$ cells.\(^{45}\) Our results showed that Akt phosphorylation was downregulated in both types of $\rho^0$ cells (Figure 8). Moreover, an apoptosis-promoting signal was activated in $\rho^0$ cells (Figure 8 and Table 2). These results indicated that the downregulation of Akt phosphorylation promoted cell death (ie, apoptosis and/or ferroptosis) in $\rho^0$ cells via upregulation of COX2.

In conclusion, the sensitivity of $\rho^0$ cells to treatment with $H_2O_2$ may be due to peroxidation of the plasma membrane, leading to increases in $H_2O_2$ permeability and cell death. Moreover, alterations in the state of the membrane may change the susceptibility of cells to drugs. These findings offer promise for the development of novel anticancer drugs, altering the oxidation state of the plasma membrane. Such drugs may be helpful in overcoming resistance to RT and drug therapy in cells.
