Abstract

Factorization of quantum mechanical Hamiltonians has been a useful technique for some time. This procedure has been given an elegant description by supersymmetric quantum mechanics, and the subject has become well developed. We demonstrate that the existence of raising and lowering operators for the harmonic oscillator (and many other potentials) can be extended to their supersymmetric partners. The double supersymmetry (or a factorization chain) is used to obtain non-singular isospectral potentials, and the explicit expressions for the ladder operators, wavefunctions and probability densities are provided. This application avoids the technical complexities of the most general approaches, and requires relatively modest methods from supersymmetric quantum mechanics.

PACS numbers: 03.65.Ge, 03.65.Fd, 03.65.Ca

In supersymmetric quantum mechanics (SUSY QM) the form of the Schrödinger equation of a particle is determined by its Hamiltonian ($\hbar = 2m = 1$):

$$H = -\frac{\partial^2}{\partial x^2} + V(x),$$

where $V(x)$ is nonsingular on $-\infty < x < \infty$ and has at least one bound state. If its ground-state wavefunction $\psi_0$ and energy $E_0$ are known, then it is always possible to factor the Hamiltonian $H_0 = H - E_0$ into a product of two linear differential operators:

$$H_0 = -\frac{\partial^2}{\partial x^2} + V_0(x) = A_0^\dagger A_0,$$

where $V_0(x)$ is the superpotential related to the potential $V_0(x)$ by the Riccati equation

$$V_0(x) = -\frac{\psi_0'}{\psi_0},$$

with primes denoting the derivative. By reversing the order of $A_0$ and $A_0^\dagger$, one obtains a new Hamiltonian

$$H_+ = A_0^\dagger A_0 = -\frac{\partial^2}{\partial x^2} + V_+^{(0)}(x) = -\frac{\partial^2}{\partial x^2} + W_0^2(x) + W_0'(x).$$
whose eigenvalues and eigenfunctions are related to those of $H^{(0)}$. For instance, the
eigenfunctions of $H^{(0)}$ ($H^{(0)}$) can be found by applying the operator $A_0$ ($A_0$) to the
eigenfunctions of $H^{(0)}$ ($H^{(0)}$). Moreover, it turns out that these partner Hamiltonians have
identical spectra (except for the ground state of $H^{(0)}$), so that having an exactly soluble problem
for $H^{(0)}$ guarantees derivation of the exact solution of $H^{(0)}$ [1].

The generalization of this formalism to the excited states $\psi_n(x)$ ($n = 1, 2, \ldots$) of $H^{(0)}$ is
straightforward [2]. It is done by introducing the operators

\[ A_n^\dagger = -\partial_x + W_n(x) \quad \text{and} \quad A_n = \partial_x + W_n(x) \]

with superpotentials $W_n(x) = -\psi_n'(x)/\psi_n(x)$. Now we have two sets of potentials $V^{(n)}_+(x) =
W_n^2(x) \pm W_n'(x)$ corresponding to the wavefunction $\psi_n(x)$. From the Schrödinger equation it follows that

\[ V^{(n)}_-(x) = V^{(0)}(x) + E_0 - E_n \]

(where $E_n$ is the energy eigenvalue corresponding to $\psi_n(x)$), so the potentials $V^{(n)}_-$ offer
nothing new. On the other hand, the potentials

\[ V^{(n)}_+(x) = 2W_n^2(x) - V^{(0)}(x) \]

are less trivial and more interesting. A few remarks about this generalization are in order here. Since

\[ H^{(n)}_+[A_n\psi_k] = A_nA_n^\dagger A_n\psi_k = A_n[H^{(n)}_[-]\psi_k] = (E_k - E_n)[A_n\psi_k], \]

one may conclude that $A_n\psi_k$ is an eigenfunction of the Hamiltonian $H^{(n)}_+$ with energy eigenvalue $E_k - E_n$ (note that the normalization condition requires $k > n$). However,
from the orthogonality of eigenfunctions $\psi_n(x)$ we know that an excited state wavefunction
changes sign at one or more points in space and consequently the superpotentials $W_n(x)$ are
always singular for $n > 0$. Therefore, the proper behavior of the wavefunction $\psi_k(x)$ does not
necessarily mean that $A_n\psi_k(x) = (\partial_x + W_n(x))\psi_k(x)$ is an acceptable solution, and the states
of $H^{(n)}_-$ are not, in general, in one-to-one correspondence with the states of $H^{(n)}_+$ unless $n = 0$,
which corresponds to the standard unbroken SUSY. That is, for excited states the degeneracy of
energy levels typically breaks down, and this breakdown explains relatively low interest
in extensions of SUSY QM to the excited states of a potential. As an illustration consider
the following exercise. One-dimensional harmonic oscillator eigenfunctions are given by

\[ \psi_n(y) = H_n(y) e^{-y^2/2} \]

where $H_n(y)$ are the Hermite polynomials and $y = \sqrt{\alpha/2}x$. The
superpotentials are easily derived by using the well-known recursion relations for Hermite polynomials:

\[ W_n(y) = \sqrt{\frac{\alpha}{2}} \left( \frac{H_{n+1}(y)}{H_n(y)} - y \right). \]

They can be used to generate the first two pairs of partner potentials according to $V^{(n)}_\pm(x) =
W_n^2(x) \pm W_n'(x)$:

\[ V^{(0)}_-(x) = \frac{\alpha^2x^2}{4} - \frac{\alpha}{2} \quad \text{and} \quad V^{(0)}_+(x) = \frac{\alpha^2x^2}{4} + \frac{\alpha}{2}; \]

\[ V^{(1)}_-(x) = \frac{\alpha^2x^2}{4} - \frac{3\alpha}{2} \quad \text{and} \quad V^{(1)}_+(x) = \frac{\alpha^2x^2}{4} - \frac{\alpha}{2} + \frac{2}{x^2}. \]

The $n = 0$ case is the standard isospectral SUSY QM (the lowest state of $V^{(0)}_-(x)$ has no
counterpart in the spectra of $V^{(0)}_+(x)$), whereas the $n = 1$ case corresponds to the generalization
of SUSY QM to the first excited state, and one expects the breakdown of the degeneracy of
energy levels. Indeed, the potential \( V^{(1)}(x) \) defined on the interval \([0, \infty)\) is known as isotonic oscillator [3]. Its eigenfunctions
\[
A_1 \psi_n(y) = \frac{\sqrt{\omega}}{2} \left( \frac{d}{dy} + y - \frac{1}{y} \right) e^{-y^2/2} H_n(y)
\]
are only nonsingular for odd \( n \) and consequently the energy level spacing is twice larger than that of its partner \( V^{(2)}(x) \), i.e. the energy levels are partially degenerate. In the next pair of potentials \( V^{(2)}(x) \) and \( V^{(2)}(x) \), degeneracy is completely absent [4]. Note that we investigate the degeneracy between the potentials \( V^{(n)}(x) \) for some fixed \( n \) and not between two unrelated pairs of potentials \( V^{(n)}(x) \) and \( V^{(n)}(x) \).

It is clear that in the traditional factorization method (i.e. the first-order SUSY QM) there is no way to use the excited states of the initial potential and at the same time avoid creating singularities in the partner potential. The second-order SUSY QM can be used to overcome this difficulty [5]. It can be formulated by the following intertwining relationship:
\[
\tilde{H}A = AH,
\]
where the two different Hamiltonians \( \tilde{H} = -\partial_x^2 + \tilde{V}(x) \) and \( H = \partial_x^2 + V(x) \) are intertwined by the operator of the second order in derivatives:
\[
A = \partial_x^2 + \eta(x) \partial_x + \gamma(x).
\]
There exist two kind of operators \( A \)—reducible and irreducible. If it is not possible to write \( A \) as a product of two first-order operators with real superpotentials, then they are referred to as irreducible [6]. In this paper we generate families of strictly isospectral potentials by using reducible operators which are equivalent to two successive first-order intertwining relations with real superpotentials. In other words, the relationship between partner potentials in our framework is the same as that obtained by the confluent algorithm [7], but the novelty of our approach is based on exploiting the non-uniqueness of factorization in the construction of partner Hamiltonians [8]. In this case there is an atypical Hamiltonian \( \tilde{H}^{(n)} \) (singular for \( n > 0 \)) that admits non-unique factorization. This Hamiltonian plays an intermediate role in the construction, and we do not discuss the degeneracy of its energy levels—we merely use it to construct two isospectral potentials. Thus, we succeed in avoiding some common obstacles (such as singular potentials, failure of the degeneracy theorem that arises when dealing with excited states, etc) by using non-uniqueness of factorization at the intermediate stage. Continuing our exercise with the harmonic oscillator we show below how to construct two one-parameter class of potentials which are not the harmonic oscillator, yet have the same energy spectrum. We explicitly derive the associated wavefunctions and plot the probability densities.

The starting point is to define the operators
\[
B_n = \partial_x + f(x) + W_n(x) \quad \text{and} \quad B_n^\dagger = -\partial_x + f(x) + W_n(x),
\]
where \( f(x) \) is the temporarily undetermined function. As usual we demand that \( \tilde{H}^{(n)} = B_n B_n^\dagger \) which results in
\[
\tilde{H}^{(n)} = -\partial_x^2 + V^{(n)}(x) + f'(x) + 2W_n(x)f(x) + f^2(x).
\]
In order to arrive at the non-unique factorization \( \tilde{H}^{(n)} = H^{(n)} \) one should set
\[
f'(x) + 2W_n(x)f(x) + f^2(x) = 0
\]
and solve for \( f(x) \). This differential equation is known as the Bernoulli equation (a specific example of the Riccati equation), and it possesses the following general solution which depends on an arbitrary integration constant \( C \) that can be considered as a free parameter:
\[
f_n(x) = \frac{\psi_n^2(x)}{C + \int_{x_0}^x \psi_n^2(s) \, ds},
\]
where \( C \) and \( x_0 \) are the constants. A little calculation shows that the partner Hamiltonian \( \tilde{H}_-^{(n)} = B_n A_n \) is given by

\[
\tilde{H}_-^{(n)} = -\frac{d^2}{dx^2} + V_-^{(n)} - 2f_n'(x) = -\frac{d^2}{dx^2} + \tilde{V}_-^{(n)}(x).
\]

Obviously, the potential \( V_-^{(n)}(x) \) is free of singularities for \( n = 0 \), and it is legitimate to discuss the degeneracy of energy levels of the potentials \( V_{-0}^{(n)}(x) \), \( V_{-1}^{(n)}(x) \), and \( V_{-2}^{(n)}(x) \) (the latter is assumed to be nonsingular for certain values of the parameter \( C \)). However, as it was pointed out earlier for the excited states, the potential \( V_{-1}^{(n)}(x) \) has singularities corresponding to the zeros of the wavefunction \( \psi_n(x) \). So, while the potential \( V_{-1}^{(n)}(x) \) is defined on the full real axis, the range of \( V_{-1}^{(n)}(x) \) is composed of \( n + 1 \) disjoint regions and their energy spectra are non-degenerate or only partially degenerate as explained above. An interesting question arises naturally: is the degeneracy theorem still valid for the potentials \( V_{-1}^{(n)}(x) \) and \( \tilde{V}_{-1}^{(n)}(x) \) under the assumption that \( V_{-1}^{(n)}(x) \) is free of singularities for certain \( C \)? We have found that the intermediate (or atypical) Hamiltonian \( \tilde{H}_-^{(n)} \) admits two different factorizations due to its non-uniqueness, namely \( A_n A_k = B_n B_k^\dagger \). Hence, we can exploit the operators \( A_n \) and \( B_n \) together with their adjoint to answer the above question.

The Schrödinger equation \( \tilde{H}_-^{(n)} \psi_k = (E_k - E_n) \psi_k \) implies

\[
\tilde{H}_-^{(n)}[B_n^\dagger A_n \psi_k] = B_n^\dagger B_n A_n^\dagger A_n \psi_k = (E_k - E_n)[B_n^\dagger A_n \psi_k],
\]

where \( k \neq n \), i.e. if \( \psi_k(x) \) is an eigenfunction of the Hamiltonian \( \tilde{H}_-^{(n)} \) with energy eigenvalue \( E_k - E_n \), then \( B_n^\dagger A_n \psi_k \) is an eigenfunction of \( \tilde{H}_-^{(n)} \) with the same energy. Similarly, from the Schrödinger equation \( \tilde{H}_-^{(n)} \tilde{\psi}_k^{(n)} = \tilde{E}_k \tilde{\psi}_k^{(n)} \) (where in \( \tilde{E}_k^{(n)} \), \( k \) denotes the energy level and \( n \) refers to the \( n \)th eigenfunction of the Hamiltonian \( \tilde{H}_-^{(n)} \)) it follows that

\[
\tilde{H}_-^{(n)}[A_n^\dagger B_n \tilde{\psi}_k^{(n)}] = \tilde{E}_k^{(n)}[A_n^\dagger B_n \tilde{\psi}_k^{(n)}].
\]

It is clear that the normalized eigenfunctions of the Hamiltonians \( \tilde{H}_-^{(n)} \) and \( \tilde{H}_-^{(n)} \) are related by

\[
\tilde{\psi}_k^{(n)}(x) = (E_k - E_n)^{-1} [B_n^\dagger A_n \psi_k(x)] \quad \text{and} \quad \psi_k(x) = (E_k - E_n)^{-1} [A_n^\dagger B_n \tilde{\psi}_k^{(n)}(x)]
\]

with \( k \neq n \). The operators \( A_n \) or \( B_n \) destroy a node in the eigenfunctions, but they are followed respectively by the operators \( B_n^\dagger \) or \( A_n^\dagger \) that create an extra node. So the overall number of the nodes does not change. In addition, the normalization does not require positive semi-definiteness of the energy eigenvalues, as in the standard case. The operator \( B_n^\dagger A_n \) can be factored and compared with the above-mentioned operator \( A = \frac{d^2}{dx^2} + \eta(x)\partial_x + \gamma(x) \). One realizes that \( -\eta(x) = f_n'(x) \) and \( -\gamma(x) = V_{-1}^{(n)}(x) + f_n(x)W_n(x) \).

For any \( n \) there is always one missing state \( k = n \) (since \( A_n \psi_n(x) = 0 \)) which can be obtained by solving the first-order differential equation \( B_n \tilde{\psi}_n^{(n)} = 0 \):

\[
\frac{d\tilde{\psi}_n^{(n)}(x)}{dx} = -\left( W_n(x) + \frac{\psi_n^2(x)}{C + \int_{x_0}^x \psi_n^2(s) \, ds} \right) \tilde{\psi}_n^{(n)}(x) = \frac{d}{dx} \left( \ln \frac{\psi_n(x)}{C + \int_{x_0}^x \psi_n^2(s) \, ds} \right) \tilde{\psi}_n^{(n)}(x).
\]

In other words,

\[
\tilde{\psi}_n^{(n)}(x) = N(C) \times \frac{\psi_n(x)}{C + \int_{x_0}^x \psi_n^2(s) \, ds}
\]

with the corresponding energy \( \tilde{E}_n^{(n)} = 0 \). All other energy eigenvalues satisfy \( \tilde{E}_n^{(n)} = E_k - E_n \). Negative energy states appear when \( n > 0 \). The normalization constant \( N(C) \) depends on the parameter \( C \) and other parameters of the initial potential \( V_{-1}^{(n)}(x) \). It is a constraint that
Figure 1. Plot of the potential $\tilde{V}_1^{(0)}(x)$ with $C = 1$ and unnormalized probability densities (dashed line at the corresponding level position) for its three lowest energy eigenvalues. The limit $C \to \infty$ corresponds to the potential $V_{-1}^{(0)}(x) = x^2 - 1$ (thick solid line).

allows one to determine the values of $C$ for which the potentials $\tilde{V}_n^{(0)}(x)$ are nonsingular and eigenfunctions $\tilde{\psi}_k(n)$ are well defined.

Let us apply the developed theory to the harmonic oscillator potential (with $\omega = 2$) whose wavefunctions $\psi_k(x) = H_k(x) e^{-x^2/2}$ and energy eigenvalues $E_k = 2k$ are well known. Considering first the $n = 0$ case, one obtains the following partner potentials:

$$V_0^{(0)}(x) = x^2 - 1 \quad \text{and} \quad \tilde{V}_0^{(0)}(x) = x^2 - 1 - 2 \frac{d}{dx} \left( \frac{e^{-x^2}}{C + \int_0^x e^{-s^2} ds} \right).$$

The latter is free of singularities when $|C| > \sqrt{\pi}/2$ (as follows from the normalization constant $N(C)$) and asymptotically behaves like $x^2 - 1$ (see figure 1).

Its eigenvalues are $\tilde{E}_k^{(0)} = 2k$, that is, identical to those of the harmonic oscillator, and the normalized ground-state wavefunction reads

$$\tilde{\psi}_0^{(0)}(x) = \frac{4\pi}{\sqrt{4C^2 - \pi}} \frac{e^{-x^2/2}}{4\sqrt{\pi}} \frac{e^{-x^2/2}}{C + \int_0^x e^{-s^2} ds}.$$

All other wavefunctions are derived through $B_0^\dagger A_0 \psi_k$ or by applying the fifth-order raising operator $(B_0^\dagger A_0) A_0^\dagger (A_0^\dagger B_0)$ repeatedly to the normalized first excited-state wavefunction of the potential $\tilde{V}_0^{(0)}(x)$:

$$\tilde{\psi}_1^{(0)}(x) = \left( \frac{4\pi}{\sqrt{\pi}} \right)^{1/4} e^{-3x^2/2} \left( 1 + 2Cx e^{x^2} + \sqrt{\pi x} \operatorname{erf}(x) e^{x^2} \right).$$

The same result was obtained by Mielnik [9] and using the Gelfand–Levitan formalism by Abraham and Moses [10]. Mielnik pointed out the third-order raising operator for this problem $b^\dagger a^\dagger b$, where $b$ and $b^\dagger$ convert the eigenfunctions of the partner Hamiltonians into one another and $a^\dagger$ is the usual creation operator. We immediately recognize that $b = A_0^\dagger B_0$
Figure 2. Plot of the potential $\bar{V}^{(1)}(x)$ with $C = 3$ and unnormalized probability densities (dashed line at the corresponding level position) for its three lowest energy eigenvalues. The limit $C \to \infty$ corresponds to the potential $V^{(1)}(x) = x^2 - 3$ (thick solid line).

and $a^\dagger = A_0^\dagger$—this is just the consequence of non-uniqueness of factorization (and in the first instance of double supersymmetry). Being able to reproduce this result is noteworthy, but another important fact is that one can obtain infinitely many such potentials (since the harmonic oscillator has infinitely many wavefunctions) and Mielnik’s result is just one of them, namely $n = 0$. We show one more example and then turn to the most general case. This time letting $n = 1$ we find a pair of partner potentials:

$$V^{(1)}_-(x) = x^2 - 3 \quad \text{and} \quad \bar{V}^{(1)}_-(x) = x^2 - 3 - 8 \frac{\mathrm{d}}{\mathrm{d}x} \left( \frac{e^{-x^2/2} - C e^{-x^2}}{\sqrt{\pi}} \text{erf}(x) \right).$$

The potential $\bar{V}^{(1)}_-(x)$ is nonsingular for $|C| > \sqrt{\pi}$ (as follows from normalizing $\bar{\psi}^{(1)}_1(x)$) and behaves like $x^2 - 3$ for large $x$ (see figure 2). Its eigenvalues are $E^{(1)}_k = 2(k - 1)$, i.e. the same as for $V^{(1)}_-(x)$ and there is one negative energy state as expected since we used the first excited state of the original potential. The normalized first excited state of the potential $\bar{V}^{(1)}_-(x)$ corresponds to the energy $\bar{E}^{(1)}_1 = 0$ and satisfies $B_1 \bar{\psi}^{(1)}_1(x) = 0$:

$$\bar{\psi}^{(1)}_1(x) = \sqrt{\frac{C^2 - \pi}{2\sqrt{\pi}}} \frac{2x e^{-x^2/2}}{C - 2x e^{-x^2} + \sqrt{\pi} \text{erf}(x)}.$$

The normalized lowest state wavefunction is given by

$$\bar{\psi}^{(1)}_0(x) = \left( \frac{1}{\pi} \right)^{1/4} \frac{e^{x^2/2}(C + \sqrt{\pi} \text{erf}(x))}{C e^{x^2} - 2x + \sqrt{\pi} \text{erf}(x) e^{x^2}}.$$

Other states $k = 2, 3, \ldots$ are obtained by the usual construction or by applying the raising operator $(B_1^\dagger A_0) A_0^\dagger (A_1 B_1)$ to the wavefunction $\bar{\psi}^{(1)}_1(x)$.

At least in the case of the harmonic oscillator one can provide explicit expressions for the pairs of isospectral potentials generated by an arbitrary excited state $\psi_n(x)$. To this end
note that we need to evaluate the integral (with \( x_0 = 0 \)) that appears in the denominator of the function \( f_n(x) \):

\[
\int_0^x \psi_n^2(s) \, ds = \int_0^x e^{-x^2} H_n^2(s) \, ds = \int_0^x ds \, e^{-x^2} \sum_{m=0}^n \frac{2^m}{m!} \frac{n!}{(n-m)!} H_{2(n-m)}(s)
\]

\[
= x (n!)^2 \sum_{m=0}^n (-1)^m \frac{2^{n-m} (2m)!}{(n-m)! (m!)^2} \, \text{}_1F_1 \left( m + \frac{1}{2}, \frac{3}{2}; -x^2 \right)
\]

where \( \text{}_1F_1(\alpha; \beta; z) \) is the confluent hypergeometric function (cf equation (46) in [7]).

Up until now we were assuming that for certain values of the parameter \( C \) the function \( f_n(x) \) is free of singularities. Of course, \( f_n(x) \) is non-singular if its denominator is nodeless, and the latter increases monotonically (the derivative of the denominator is positive for all \( x \)). Thus, one obtains non-singular potentials \( \tilde{V}(n) \) strictly isospectral to the harmonic oscillator \( V(0) = x^2 \) for \( n = 0 \) and \( n = 1 \). The same result (up to the choice of the energy scale) was explored for the first time in [7]. We would like to stress that for a given \( n \) we supersymmetrize the original potential by subtracting the appropriate energy.

Continuing our theme of potentials with the oscillator spectrum let us finally apply the presented method to the exactly solvable non-polynomial one-dimensional quantum potential discovered recently by Cariñena, Perelomov, Rañada and Santander (CPRS) [11]. In their original manuscript the authors solved the Schrödinger equation for the potential

\[
V_{\text{CPRS}}(x) = \frac{x^2}{2} + \frac{2x^2 - 1}{(2x^2 + 1)^2}
\]

assuming that the solution can be expressed as a power series in \( x \) and deriving the recursion formula which determines the coefficients of the expansion. Later a much more simple solution was obtained by Fellows and Smith [12] who showed that the potential \( V^{(1)}(x) = 2V_{\text{CPRS}} + 3 \) is a supersymmetric partner of the harmonic oscillator \( x^2 + 5 \). We further analyze the CPRS potential with the aim to find new potentials with the spectrum of a simple oscillator. The energy eigenvalues and unnormalized wavefunctions of the potential \( V^{(1)}(x) \) are given by \( E_k = 2k \) and

\[
\psi_k(x) = \frac{H_k(x) + 4k H_{k-2}(x) + 4k(k-3)H_{k-4}(x)}{2x^2 + 1} e^{-x^2/2} = \frac{P_k(x)}{2x^2 + 1} e^{-x^2/2}
\]

with \( k = 0, 3, 4, 5, \ldots \). Knowing one of the excited-state wavefunctions, say

\[
\psi_3(x) = \frac{4x(3 + 2x)}{2x^2 + 1} e^{-x^2/2},
\]

one can generate a pair of potentials with identical spectra (see figure 3):

\[
V^{(3)}(x) = x^2 - 3 + \frac{2x^2 - 1}{(2x^2 + 1)^2} \quad \text{and}
\]

\[
\tilde{V}^{(3)}(x) = V^{(3)}(x) + 2 \frac{d}{dx} \left( \frac{16x^2(2x^2 + 3)^2}{8x(4x^4 + 8x^2 + 3) - e^{x^2}(2x^2 + 1)^2(C + 12\sqrt{\pi}\text{erf}(x))} \right)
\]
Figure 3. Plot of the potential $\tilde{V}^{(3)}(x)$ with $C = 21.5$ (close to $12\sqrt{\pi}$) and unnormalized probability densities (dashed line at the corresponding level position) for its three lowest energy eigenvalues. The limit $C \to \infty$ corresponds to the CPRS potential $V^{(3)}(x)$ (thick solid line).

The latter is free of singularities for $|C| > 12\sqrt{\pi}$. It might seem very unexpected that this highly non-trivial potential possesses such a simple spectrum as $E_{k}^{(3)} = 2k - 6$ for $k = 0, 3, 4, 5, \ldots$. Its first excited-state wavefunction reads

$$\psi^{(3)}_{3}(x) = \sqrt{\frac{C^2 - 144\pi}{24\sqrt{\pi}}} \frac{4x(2x^2 + 3)e^{x^2/2}}{e^x(2x^2 + 1)(C + 12\sqrt{\pi}\text{erf}(x)) - 8x(2x^2 + 3)}.$$  

The eigenfunctions with $k \neq n$ are obtained by applying the operator $B_n A_n$ to the wavefunctions $\psi_k(x)$ of the original potential $V^{(0)}(x)$.

It turns out that for this problem too one can write the partner potentials generated by an arbitrary excited state $\psi_n(x)$. We need the following two identities which are valid for any $n \geq 3$ (proofs can be found in [11]):

$$P'_n(x) = 4n(2x^2 + 1)H_{n-3}(x) \quad \text{and} \quad \frac{P_n(x)e^{-x^2}}{(2x^2 + 1)^2} = -2\frac{d}{dx}\left(\frac{H_{n-3}(x)e^{-x^2}}{2x^2 + 1}\right).$$

Using these identities and integrating by parts we find

$$\int_0^x \psi_n^2(s) \, ds = -\frac{2P_n(x)H_{n-3}(x)e^{-x^2}}{2x^2 + 1} + 8n \int_0^x e^{-s^2}H_{n-3}^2(s) \, ds$$

$$= -\frac{2P_n(x)H_{n-3}(x)e^{-x^2}}{2x^2 + 1} + x8n((n - 3)!)^2 \sum_{m=0}^{n-3} (-1)^m \frac{2^{m-3}(2m)!}{(n - m - 3)! (m!)^3} \, \text{F}_1\left(m + \frac{1}{2}, \frac{3}{2}; -x^2\right).$$
Hence for any given \( n \), the potentials

\[
V^{(n)}_-(x) = \frac{\psi''_n(x)}{\psi_n(x)} = x^2 + 8 \frac{2x^2 - 1}{(2x^2 + 1)^2} - 2n + 3 \quad \text{and} \quad \tilde{V}^{(n)}_-(x) = V^{(n)}_-(x) - 2f''_n(x)
\]

are strictly isospectral with energy eigenvalues \( 2(k - n) \) where \( k, n = 0, 3, 4, 5, \ldots \). The potentials \( \tilde{V}^{(n)}_-(x) \) are non-singular for \(|C| > (n - 3)!2^{n-1}n\sqrt{\pi} \) with \( n \geq 3 \). We calculated \( V^{(n)}_-(x) \) using the following identity which does not appear in [11] where some properties of the polynomials \( P_n(x) \) have been studied:

\[
\frac{2x(2x^2 + 5)}{2x^2 + 1} \frac{P''_n(x)}{P_n(x)} = \frac{P''_n(x)}{P_n(x)} = 2n.
\]

The canonical form for this identity is the Schrödinger equation for the CPRS potential.

The above discussion illustrates a general method for constructing isospectral potentials in the second-order SUSY QM. Given the wavefunctions \( \psi_k \) and energy eigenvalues \( E_k - E_0 \) of the Hamiltonian \( H^{(0)} \) we automatically get the wavefunctions \( \psi_k \) and energy eigenvalues \( E_k - E_n \) of the Hamiltonians \( H^{(n)} \). This allows one to construct the Hamiltonian \( \tilde{H}^{(n)} \) whose energy spectra are identical to those of \( H^{(n)} \) and eigenfunctions are given by \( \tilde{\psi}^{(n)}_k(x) \propto B_n^1 A_n \psi_k(x) \) for \( k \neq n \). Intertwining operators of higher order in derivatives have been studied [13]. For the third-order reducible operator there will be two atypical Hamiltonians arising from the non-uniqueness of factorization. If the possibility of using operators is available (as when one uses excited states), then the operators inherit the property of being ladder operators at each stage.

We presented simple examples to show the technique of constructing isospectral potentials, and we have tested our results on the consistency with other methods. It is well known [14] that ladder operators can be constructed for other potentials such as Morse, Pöschl–Teller and the infinite square well. The raising and lowering operators for the double-supersymmetric partner potentials can be obtained along the same lines as illustrated in this paper. This avoids the unnecessarily technical challenges in the general problem, and these potentials will be the subject of future investigations.
