Can we Beat the Square Root Bound for ECDLP over $\mathbb{F}_{p^2}$ via Representations?

Claire Delaplace and Alexander May*

Horst Görtz Institute for IT Security
Ruhr University Bochum, Germany

Abstract. We give a 4-list algorithm for solving the Elliptic Curve Discrete Logarithm (ECDLP) over some quadratic field $\mathbb{F}_{p^2}$. Using the representation technique, we reduce ECDLP to a multivariate polynomial zero testing problem. Our solution of this problem using bivariate polynomial multi-evaluation yields a $p^{1.314}$-algorithm for ECDLP. While this is inferior to Pollard’s Rho algorithm with square root (in the field size) complexity $O(\sqrt{p})$, it still has the potential to open a path to an $o(p)$-algorithm for ECDLP, since all involved lists are of size as small as $p^{3/4}$, only their computation is yet too costly.

1 Introduction

Given an elliptic curve $E$, defined over a finite field $\mathbb{F}_q$ and two points $P$ and $Q$ on this curve, the elliptic curve discrete logarithm problem (ECDLP) consists in recovering $k$ modulo order of $P$ such that $Q = kP$, if it exists.

Nowadays, ECDLP-based cryptosystems are omnipresent in everyday life cryptography, as they are widely spread in cryptographic suites such as TLS.

Many algorithms for ECDLP have been proposed in the literature from Shanks Baby-Step Giant-Step [Sha71], to Weil descent and index calculus methods [FG98,GS99,GHS02a,GHS02b,Gau09]. Other algorithms have been designed for particular cases, such as elliptic curves over a field $\mathbb{F}_p$ of group order exactly $p$ [SA'98,Sma99], or in a subgroup of order $p$ [Sem98]. We refer the reader to [GG16] for an overview of ECDLP algorithms.

Pollard’s Rho algorithm offers the best time and space complexity for elliptic curves defined over a finite field $\mathbb{F}_p$, where $p$ is prime, with a running time of $O(\sqrt{p})$ and constant memory (e.g. using Floyd’s cycle finding algorithm). Pollard’s Rho method basically creates a sequence $(R_i)_{i \geq 1}$ of elements of $\langle P \rangle$ with $R_0 = O$ and $R_{i+1} = g(R_i)$ for a well chosen function $g$, such that each $R_i$ satisfies $R_i = a_iP + b_iQ$. Once a collision appears between two elements $R_i$ and $R_j$, we have $(a_i - a_j)P = (b_j - b_i)Q$. Provided that $b_i \neq b_j$, it follows that $Q = \frac{a_i - a_j}{b_j - b_i}P$.

When the elliptic curve is defined over $\mathbb{F}_{p^n}$ for $n \geq 2$, and $p$ being a prime or a power of a prime, it is possible to perform what is called a Weil Descent.

* Funded by DFG under Germany’s Excellence Strategy - EXC 2092 CASA - 390781972.
The core idea of Gaudry’s algebraic factor-base algorithm [Gau09] for $\mathbb{F}_{p^n}$ is to split a point into an $n$-sum of points from a factor base that is defined over the base field $\mathbb{F}_p$. Using Semaev’s summation polynomials [Sem04], the split can be computed via a Gröbner basis computation. Such a computation yields a relation between factor base elements. If at least $q$ – the size of the factor base – such relations are collected, ECDLP can be solved via linear algebra. In total, Gaudry’s method runs in time $O\left(p^{2-\frac{1}{2}}\right)$, which is for $n = 2$ no better than Pollard’s Rho algorithm. Moreover, with a factor base of size $p$, there is no hope to obtain an $o(p)$-algorithm. Yet, variations of the factor base might be possible as demonstrated in Petit et al. [PKM16].

Our contribution. Our (ultimate) goal is to break the square root bound for ECDLP over $\mathbb{F}_p^2$ by designing a 4-list algorithm using the representation technique. The representation technique already proved to be useful to break the square-root barrier in the context of the subset-sum problem [HGJ10,BCJ11].

We define a problem, called Zero-Join ($\textit{ZJ-Problem}$), which given two lists $A$ and $B$ of points of $\mathbb{F}_p^2$, and a polynomial $f \in \mathbb{F}_p[X_1, X_2, X_3, X_4]$ consists in returning a list $C$ of all $((x_1, y_1), (x_2, y_2)) \in A \times B$ such that $f(x_1, y_1, x_2, y_2) = 0$.

We show that $A$ and $B$ are such that $|A| \cdot |B| = p^2$. Moreover, we show that any algorithm which solves the $\textit{ZJ-Problem}$ in time $T$ and in memory $M$ also solves ECDLP over $\mathbb{F}_p^2$ in time $T$ and memory $M$. In particular, if $|A| = |B| = p^2$, and in (the extreme) case that the $\textit{ZJ-Problem}$ could be solved in time linear in $|A|$ and $|B|$, ECDLP could be solved in $O\left(p^{\frac{3}{2}}\right)$. A trivial solution to the $\textit{ZJ-Problem}$ can be achieved in quadratic time which results in a $p^{\frac{3}{2}}$-algorithm. However, we show that the $\textit{ZJ-Problem}$ admits sub-quadratic solutions. When using multi-evaluation techniques for bivariate polynomials, we achieve a $p^{1.314}$-algorithm. We leave it as an open problem whether this can be further improved.

Organisation of the paper. In Section 3, we present our new ECDLP 4-list algorithm for an elliptic curve defined over $\mathbb{F}_p^2$, for any prime $p > 3$. We also show that ECDLP reduces to the $\textit{ZJ-Problem}$. Finally, we present a sub-quadratic algorithm to solve the $\textit{ZJ-Problem}$ in Section 4, resulting in our $p^{1.314}$-algorithm.

2 Preliminaries

For any integer $r$, we denote by $\mathbb{Z}_r$ the ring $\mathbb{Z}/r\mathbb{Z}$. For any two integers $a < b \in \mathbb{Z}$, we denote by $[a, b]$ the set of all integers $a \leq k \leq b$ and by $[a, b)$ the set of all integers $a \leq k < b$. For any $n > 0$, we denote by $\log n$ the logarithm in basis 2 of $n$. For any real $x$, we denote by $\lfloor x \rfloor$ the rounding to the closest integer to $x$, when tied, we round to the greater one. Let us denote $\mathbb{F}_p$ the finite field with $p$ elements. Let $x$ be an element of $\mathbb{F}_p^2$, $x = x^{(0)} + \alpha x^{(1)}$, such that there exists $\beta \in \mathbb{F}_p$ and $\alpha$ is a root of $X^2 \beta$, which is irreducible over $\mathbb{F}_p$. Let $B$ be a basis of $\mathbb{F}_p^2$ with respect to $\alpha$. The vector $(x^{(0)}, x^{(1)}) \in \mathbb{F}_p^2$ in basis $B$ is uniquely associated to $x$. 

2
Let \( q = p^n \) for \( n \geq 1 \), and \( p > 3 \) prime. Let \( \mathbb{F}_q \) be a finite field and let \( \mathbf{E} \) be an elliptic curve over \( \mathbb{F}_q \). We denote by \( O \) the point at infinity of \( \mathbf{E} \). The group \( \mathbf{E}(\mathbb{F}_q) \) is the group of all the points in \( \mathbf{E} \). As \( p > 3 \), we can define \( \mathbf{E} \) in Weierstraß form. In particular, there is a function \( f : \mathbb{F}_q \rightarrow \mathbb{F}_q \) that maps elements \( x \) to \( f(x) = x^3 + ax + b \), for some \( a, b \in \mathbb{F}_q \) such that the set of points \( \mathbf{E}(\mathbb{F}_q) \) equals \( \{ P = (x, y) \in \mathbb{F}_q^2 : y^2 = f(x) \} \cup \{O\} \). Although there are other ways to represent an elliptic curve, in this paper, we focus on the Weierstraß model.

Let \( S_1 \) and \( S_2 \) be subsets of \( \mathbb{N} \), we denote by \( S_1 + S_2 \) the set of integers \( z \) such that \( z = x + y \) with \( x \in S_1 \) and \( y \in S_2 \), and for all \( \ell \in \mathbb{N} \), we denote by \( \ell S_1 \) the set of integers \( z \) such that \( z = \ell x \) with \( x \in S_1 \).

Let \( L \) be a list. We consider \( L \) as a tuple \((\ell_0, \ldots, \ell_{N-1})\), where \( N = |L| \geq 0 \). We denote by \( L[i] \) the \((i + 1)\)-th element of the list. Given two lists \( L_1 = (\ell_0, \ldots, \ell_N) \) and \( L_2 = (t_0, \ldots, t_M) \), we denote by \( L_1 + L_2 \) the list \((\ell_0 + t_0, \ell_0 + t_1, \ldots, \ell_0 + t_M, \ldots, \ell_N + t_M)\). An empty list is denoted by \( \perp \).

Complexities. We use the standard Landau notations to describe the complexities presented in this paper. The time complexities are given in number of elementary operations (negation, addition, multiplication, inverse) over \( \mathbb{F}_p \), and the memory complexities in number of elements of \( \mathbb{F}_p \) that are to be stored. Using this convention, elementary operations over \( \mathbb{F}_{p^2} \) and sum of two points of the group \( \mathbf{E}(\mathbb{F}_{p^2}) \) are performed in time \( O(1) \), and storing an element of \( \mathbb{F}_{p^2} \) or a point of \( \mathbf{E}(\mathbb{F}_{p^2}) \) requires \( O(1) \) memory.

Discrete logarithm over an elliptic curve. Let \( \mathbf{E} \) be an elliptic curve over a finite field \( \mathbb{F}_q \). Let us denote by \( |\mathbf{E}(\mathbb{F}_q)| \) the order of the group (i.e. the cardinality of \( \mathbf{E}(\mathbb{F}_q) \)). By Hasse’s Theorem, we know that \( |\mathbf{E}(\mathbb{F}_q)| = O(q) \). Let \( P \) be a point of \( \mathbf{E}(\mathbb{F}_q) \). The order \( r \) of \( P \) is the cardinality of the cyclic group \( \langle P \rangle = \{ O, P, 2P, \ldots , (r-1)P \} \). It is also the first integer \( \ell > 0 \) such that \( \ell P = O \). As \( \langle P \rangle \) is a subgroup of \( \mathbf{E}(\mathbb{F}_q) \), it is clear that \( r \leq |\mathbf{E}(\mathbb{F}_q)| \).

**Definition 1 (\( \text{ECDLP} \)).** Let \( \mathbb{F}_q \) be a finite field, and let \( \mathbf{E} \) be an elliptic curve over \( \mathbb{F}_q \). Let \( P \) be a point of \( \mathbf{E}(\mathbb{F}_q) \) of prime order \( r = O(q) \). Let \( G = \langle P \rangle \). Given \( P \) and \( Q \) in \( G \), solving the discrete logarithm problem over \( \mathbf{E} \) consists in recovering \( k \in \mathbb{Z}_r \) such that \( kP = Q \).

We are interested in the case where \( q = p^2 \), for a prime \( p > 3 \). We call this particular variant \( p^2\text{-ECDLP} \).

**Representation Technique.** In [HGJ10], Howgrave-Graham and Joux introduced the representation technique to improve methods for the subset-sum problem. Given a vector \( \mathbf{a} \in \mathbb{Z}^n \) and a target \( t \) in \( \mathbb{Z} \) the problem basically consists in finding a vector \( \mathbf{e} \in \{0,1\}^n \) such that \( \langle \mathbf{a, e} \rangle = t \). When the solution \( \mathbf{e} \) consists exactly of \( n/2 \) non-zero coefficients, Howgrave-Graham and Joux noticed that it can be split into sums of two vectors \( \mathbf{e} = \mathbf{e}_1 + \mathbf{e}_2 \), where \( \mathbf{e}_1 \) and \( \mathbf{e}_2 \) both consist of \( n/4 \) one coefficients, in \( \binom{n/4}{2} \) different ways. It is enough to find only one of these representations to recover a solution to the problem, thus additional
constraints can be enforced on the dot products \((\mathbf{a}, \mathbf{e}_1)\) and \((\mathbf{a}, \mathbf{e}_2)\), so that only one of these representation survives. This yields a \(2^{0.337n}\) algorithm for subset-sum that breaks the square root bound.

We would like to transfer this idea to the \(p^2\)-ECDLP problem.

**Definition 2 (Representation).** Let \(\ell > 0\), \(r \in \mathbb{N}\), \(k \in \mathbb{Z}\), and let \(S_1, \ldots, S_\ell\) be subsets of \(\mathbb{N}\). A tuple \((k_1, \ldots, k_\ell) \in S_1 \times \cdots \times S_\ell\) is a representation of \(k\) if \(k = k_1 + \cdots + k_\ell \mod r\).

### 3 New ideas to solve \(p^2\)-ECDLP

Let \(E(\mathbb{F}_{p^2})\) be an elliptic curve defined over \(\mathbb{F}_{p^2}\), with \(p > 3\). Let \(r\) be the order of \(E(\mathbb{F}_{p^2})\), which can be computed in time polynomial in \(\log p\) with Schoof’s algorithm [Sch85, Sch95]. Since we are interested in cryptographic applications we assume that \(r\) is prime. By Hasse’s theorem we know that \(r \approx p^2\). Let \(P\) generate \(E(\mathbb{F}_{p^2})\) and let \(Q = kP\) for some unknown \(k \in \mathbb{Z}_r\) that we want to compute.

First notice that for all \((k_1, k_2) \in \mathbb{Z}_p^2\), \((k_1 + k_2)P = Q\) is equivalent to \(k_1P = Q - k_2P\). In the following we try to recover such a tuple \((k_1, k_2)\).

**Heuristic.** For the complexity analysis of our algorithm, we assume that the points of \(E(\mathbb{F}_{p^2})\) are uniformly distributed over \(\mathbb{F}_{p^2}^2\). The results of Kim, Tiboouchi [KT19] provide some theoretical justification for our assumption.

#### 3.1 Solving \(p^2\)-ECDLP Using the Representation Technique

First note that every positive integer \(s\) can be uniquely decomposed as

\[
s = s_0 + s_1 \lfloor \sqrt{p} \rfloor + s_2p,
\]

by computing first the integer division of \(s = s_2p + \bar{s}\) by \(p\), and then the integer division of \(\bar{s} = s_0 + s_1 \lfloor \sqrt{p} \rfloor\) by \(\lfloor \sqrt{p} \rfloor\). In this case, \(s_0, s_1, s_2\) are in \(\mathbb{N}\) such that \(0 \leq s_0 < \lfloor \sqrt{p} \rfloor\), \(0 \leq s_1 < p \cdot \lfloor \sqrt{p} \rfloor\)^{-1}\) and \(s_2 \geq 0\).

With respect to this decomposition, we denote by \(S_1\) and \(S_2\) the subsets of \([0, r)\) such that

\[
S_1 = \{s = s_0 + s_2p\}, \quad S_2 = \{s = s_1 + s_2p\}.
\]

Informally, the bits of the elements of \(S_1\) and \(S_2\) are dispatched as shown in Figure 1a. We consider \(k\) as the sum \(k_1 + k_2\) where \(k_1 \in S_1\) and \(k_2 \in S_2\). Since \(k_1, k_2\) overlap in \(\log \left(\frac{2}{p}\right)\) bits we expect that each \(k\) has at least \(\frac{2}{p} \approx p\) representations as a sum \(k_1 + k_2\). This is shown more formally in the following lemma.

**Lemma 1.** There are at least \(\frac{2}{p} + 1\) representations of \(k\) as the sum \(k_1 + k_2\) with \((k_1, k_2) \in S_1 \times S_2\).
Fig. 1: Bits repartition of the elements of $S_i$ and $T_j$ for $i \in [1,2]$, $j \in [1,3]$.

Proof. Let $\bar{k} = \bar{k}_0 + \bar{k}_1 \lfloor \sqrt{p} \rfloor + \bar{k}_2 p \in [0,r)$ be such that $\bar{k} \pmod{r} = k$, and let $\hat{k} = \hat{k} + r = \hat{k}_0 + \hat{k}_1 \lfloor \sqrt{p} \rfloor + \hat{k}_2 p$ when decomposed as in Equation 1. We denote by $S_{11}$ the subset of $S_1$ of the elements $s = \bar{k}_0 + s_2 p$, and by $S_{12}$ the subset of $S_1$ of the elements $s = \hat{k}_0 + s_2 p$.

We first show that for any $k_1 \in S_{11}$ such that $k_1 \leq \bar{k}$, there exists some $k_2 \in S_2$ such that $k_1 + k_2 = \bar{k}$. Then we claim that for any $k_1 \in S_{12}$, such that $k_1 > \bar{k}$, there is a $k_2 \in S_2$ such that $k_1 + k_2 = \hat{k}$.

Let $k_1 \in S_{11}$ be arbitrary such that $k_1 \leq \bar{k}$. From the definition of $S_{11}$, $k_1 = \bar{k}_0 + k_{12} p$. In particular $k_1 \leq \bar{k}$ means that $\bar{k}_2 - k_{12} \geq 0$, and as $\bar{k} < r$, $\bar{k} - k_1 \in [0,r)$. Finally we have

$$\bar{k} - k_1 = \bar{k}_0 + \bar{k}_1 \lfloor \sqrt{p} \rfloor + \bar{k}_2 p - \bar{k}_0 - k_{12} p$$

$$= \bar{k}_1 \lfloor \sqrt{p} \rfloor + (\bar{k}_2 - k_{12}) p \in S_2.$$

Let now $k_1 \in S_{12}$, such that $k_1 > \bar{k}$. First note that $k_1 < r < \hat{k}$. From the definition of $S_{12}$, $k_1 = \hat{k}_0 + k_{12} p$, and $\bar{k} - k_1 \geq 0$ means that in particular
\( \hat{k}_2 - k_{12} \geq 0 \). Furthermore as \( k_1 > \hat{k}, \hat{k} - k_1 = r + \hat{k} - k_1 \in [0, r) \). Finally

\[
\hat{k} - k_1 = \hat{k}_0 + \hat{k}_1 \lfloor \sqrt{p} \rfloor + k_{2p} - k_{12p} = \hat{k}_1 \lfloor \sqrt{p} \rfloor + (\hat{k}_2 - k_{12})p \in S_2.
\]

It follows that the number of representations \((k_1, k_2) \in S_1 \times S_2\) of \( k \) is at least equal to the number \( N_1 \) of elements of \( S_{11} \) that are smaller than \( \hat{k} \) plus the number \( N_2 \) of elements of \( S_{12} \) that are bigger than \( \hat{k} \). \( N_1 \) is the number of \( k_1 = \hat{k}_0 + k_{12p} \) such that \( 0 \leq k_{12} \leq \hat{k}_2 \), meaning that \( N_1 = \hat{k}_2 + 1 \). \( N_2 \) is the number of \( k_1 = \hat{k}_0 + k_{12p} \) such that \( \hat{k}_2 \leq k_{12} < \frac{\hat{p}}{p} \), meaning that \( N_2 \approx \frac{\hat{p}}{p} - \hat{k}_2 \). It follows that there are at least \( \frac{\hat{p}}{p} + 1 \) representations of \( k \) in \( S_1 \times S_2 \).

Out of the \( \frac{\hat{p}}{p} + 1 \approx p \) representations of \( k \) as \( k_1 + k_2 \), \((k_1, k_2) \in S_1 \times S_2\) it suffices to compute a single one. Therefore, computing only a \( \frac{1}{p} \)-fraction of all points \((P_1, P_2) = (k_1 P, Q - k_2 P)\) is sufficient to compute \( k \). In order to compute a \( \frac{1}{p} \)-fraction we restrict to those points \((P_1, P_2)\) whose \( x\)-coordinate lies in the base field (i.e. \( P_i = (x, y) \) with \( x \in \mathbb{F}_p \)).

More precisely, we proceed as follows. We compute a list \( L \) of all \( P_1 = k_1 P = (x, y) \) such that \( x \in \mathbb{F}_p \) and \( k_1 \in S_1 \). Moreover, we compute a list \( L' \) of all \( P_2 = Q - k_2 P = (x', y') \) for \( k_2 \in S_2 \) such that \( x' \in \mathbb{F}_p \). Then we search for a collision in \( L \) and \( L' \). This gives us \( k \) as the sum of the corresponding \( k_1 \) and \( k_2 \).

This results in \( \text{RepECDLP} \), described in Algorithm 2. Notice that the resulting lists \( L, L' \) have expected size only \( p^{1/2} \), since we impose a \( \frac{1}{p} \) restriction on a search space of size \( p^{2/3} \).

Now let us turn to the tricky part, the computation of \( L, L' \). Let \( 0 < \lambda < \frac{1}{2} \) be a parameter and let \( T_1, T_2, T_3 \) be three sets of elements of \([0, r)\) such that

\[
T_1 = \{ s = s_0 + ps_1 \in S_1 : s_1 \in [0, \lfloor \frac{p}{\lambda} \rfloor) \}
\]

\[
T_2 = \{ s = ps_1 \in S_1 \cap S_2 : s_1 = t \lfloor \frac{p}{\lambda} \rfloor \in [0, p) \}
\]

\[
T_3 = \{ s = s_0 + ps_1 \in S_2 : s_1 \in [0, \lfloor \frac{p}{\lambda} \rfloor) \}
\]

The bit repartition of the elements of \( T_1, T_2 \) and \( T_3 \) is given by Figure 1b. The reader is advised to use the illustration in Figure 2 for the following description.

We consider \( k_1, k_2, k_3, k_4 \), such that \( k_1 \in T_1, k_2, k_4 \in T_2, \) and \( k_3 \in T_3 \). It is clear that \( k_1 + k_2 \in S_1 \) and \( k_3 + k_4 \in S_2 \) (see Figure 1). We create the list \( L_1 \) of \((P_1, k_1)\) such that \( P_1 = k_1 P \) for all \( k_1 \in T_1 \), the list \( L_2 \) of \((P_2, k_2)\) such that \( P_2 = k_2 P \) for all \( k_2 \in T_2 \), the list \( L_3 \) of \((P_3, k_3)\) with \( P_3 = Q - k_3 P \) for all \( k_3 \in T_3 \), and the list \( L_4 \) of \((P_4, k_4)\) with \( P_4 = -k_4 P \) for all \( k_4 \in T_4 \). From here, we compute the list \( L = \{(P_{12}, k_1 + k_2) : (P_1, k_1) \in L_1, (P_2, k_2) \in L_2, P_{12} = P_1 + P_2 = (x, y) \text{ with } x \in \mathbb{F}_p \}. \) Then for all \((x', y') = P_3 + P_4 \) with \( x' \in \mathbb{F}_p \) we check if \((x', y') \in L \) and if so return the sum of the corresponding \( k_1, k_2, k_3, k_4 \).

In other words, we consider the following problem.

\footnote{If this approach fails to produce a representation of \( k \), we could rerandomize our ECDLP-instance and start over.}
Algorithm 1 \texttt{BuildLists}(E, P)

\textbf{Require:} An elliptic curve $E$ over $\mathbb{F}_{p^2}$, a point $P \in E(\mathbb{F}_{p^2})$.
\textbf{Ensure:} $L_1, L_2, L_3, L_4$.

1: \textbf{for} $i \in [1, 4]$ \textbf{do}
2: \hspace{1em} $L_i \leftarrow \bot$
3: \hspace{1em} $(k_1, k_2) \leftarrow (1, 0)$
4: \hspace{1em} $P_2 \leftarrow O$
5: \hspace{1em} \textbf{for} $1 \leq i \leq p^\lambda$ \textbf{do} \hspace{1em} \texttt{Build lists $L_1$ and $L_3$}
6: \hspace{2em} $P_i \leftarrow P + P_2$
7: \hspace{2em} \textbf{for} $1 \leq j < p^\frac{1}{2}$ \textbf{do}
8: \hspace{3em} $L_1 \leftarrow L_1 \cup \{(P_1, k_1)\}$
9: \hspace{3em} $P_1 \leftarrow P_1 + P; k_1 \leftarrow k_1 + 1$
10: \hspace{2em} \textbf{if} $i = 1$ \textbf{then} \hspace{1em} \texttt{Only on the first iteration}
11: \hspace{3em} $P_0 \leftarrow P_1; k_0 \leftarrow k_1$
12: \hspace{3em} $P_2 \leftarrow P_1; k_2 \leftarrow k_1$
13: \hspace{2em} \textbf{for} $1 \leq j < p^\frac{1}{2}$ \textbf{do}
14: \hspace{3em} $L_3 \leftarrow L_3 \cup \{(Q - P_2, k_2)\}$
15: \hspace{3em} $P_2 \leftarrow P_2 + P_0; k_2 \leftarrow k_2 + k_0$
16: \hspace{2em} \textbf{if} $i < p^\lambda$ \textbf{then} \hspace{1em} \texttt{In all iterations except the last one}
17: \hspace{3em} $L_1 \leftarrow L_1 \cup \{(P_2, k_2)\}$
18: \hspace{3em} $L_3 \leftarrow L_3 \cup \{(Q - P_2, k_2)\}$
19: \hspace{2em} $P_1 \leftarrow P_2; k_1 \leftarrow k_2$
20: \hspace{2em} \textbf{for} $0 \leq i < r p^{-(1 + \lambda)}$ \textbf{do} \hspace{1em} \texttt{Build lists $L_2$ and $L_4$}
21: \hspace{3em} $L_2 \leftarrow L_2 \cup \{(P_2, k_2)\}$
22: \hspace{3em} $L_4 \leftarrow L_4 \cup \{(-P_2, k_2)\}$
23: \hspace{3em} $P_2 \leftarrow P_2 + P_1; k_2 \leftarrow k_2 + k_1$

\textit{Problem 1.} Given two lists $L_1$ and $L_2$ of points $P \in E(\mathbb{F}_{p^2})$, compute the list $L = \{(x, y) = P_1 + P_2; P_1 \in L_1, P_2 \in L_2, x \in \mathbb{F}_p\}$

We claim that any algorithm solving Problem 1 can be used as the main routine to solve the $p^\lambda$-ECDLP problem. Our whole $\texttt{RepECDLP}$ algorithm is summarised in Algorithm 2. The \texttt{BuildLists} algorithm, described in Algorithm 1 builds the lists $L_i$ for $i \in [1, 4]$ and we denote by ECJoin an algorithm solving Problem 1, with a slight modification that does not influence the run time: the input lists contain tuples $(P_i, k_i)$, where $k_i$ is an element of $[0, r)$, the output list must also contain tuples $(P_i + P_2, k_1 + k_2)$.

The following lemma gives the complexities of \texttt{BuildLists}.

\textbf{Lemma 2.} The \texttt{BuildLists} procedure constructs lists of sizes

\begin{align*}
|L_1| = |L_3| = p^\frac{1}{2} + \lambda & \text{ and } |L_2| = |L_4| = p^{1 - \lambda} \\
& \text{ in } \mathcal{O}\left(\max\left(p^{\frac{1}{2} + \lambda}, p^{(1 - \lambda)}\right)\right) \text{ field operations using memory } \mathcal{O}\left(\max\left(p^{\frac{1}{2} + \lambda}, p^{(1 - \lambda)}\right)\right).
\end{align*}

\textit{Proof.} We start by proving the time complexity. It is dominated by the runtime of the two main for-loops: the one at line 5, which fills $L_1$ and $L_3$, and the one
at line 20, which fills \( L_2 \) and \( L_4 \). The first one is iterated \( p^\lambda \) times, and each iteration takes time \( p^{1/2} \). Indeed, each iteration consists in a constant number of elementary operations in \( \mathbb{F}_p \) and two for-loops which are each iterated \( p^{1/2} \), and whose iterations consist in \( \mathcal{O}(1) \) elementary operations in \( \mathbb{F}_p \). Thus the whole execution of the for-loop line 5 requires to perform \( \mathcal{O} \left( p^{\frac{1}{2}+\lambda} \right) \) operations. The for-loop line 20 is iterated \( r p^{-\left(1+\lambda\right)} \) times, and each iterations consists in a constant number of elementary operations over \( \mathbb{F}_p \). The claimed complexity follows.

We now show that the memory required is indeed \( \mathcal{O} \left( \max(p^{\frac{1}{2}+\lambda}, r p^{-\left(1+\lambda\right)}) \right) \).

The memory complexity is dominated by the storage of the four lists. Now, for \( i \in [1,4] \), \( L_i \) contains \( \mathcal{O}(\vert L_i \vert) \) elements of \( \mathbb{F}_p \). As such, the memory complexity of the whole procedure is \( \mathcal{O}(\max_i(\vert L_i \vert)) \). Furthermore, \( \vert L_1 \vert = \vert L_3 \vert = p^{\frac{1}{2}+\lambda} \) and \( \vert L_2 \vert = \vert L_4 \vert = r p^{-\left(1+\lambda\right)} \). As \( r = \mathcal{O}(p^2) \), \( \vert L_2 \vert = \vert L_4 \vert = \mathcal{O}(p^{1-\lambda}) \), which proves the given complexities.

\[ \square \]

Remark 1. Notice that the choice \( \lambda = \frac{1}{4} \) implies that all lists have size \( \mathcal{O} \left( p^{\frac{1}{4}} \right) \).

However, as we will discuss in section 4, unbalanced list sizes might lead to time improvements.

### 3.2 Computing the Join

We now need to find a way to check whether a point \((x, y) = P_1 + P_2\) satisfies \( x \in \mathbb{F}_p \), knowing only the coordinates \((x_1, y_1)\) of \( P_1 \) and \((x_2, y_2)\) of \( P_2 \). We have

\[
x = \frac{(y_1 - y_2)^2}{(x_1 - x_2)^2} - x_1 - x_2,
\]

and therefore

\[
(x_1 - x_2)^2(x_1 + x_2 + x) = y_1^2 + y_2^2 - 2y_1y_2
\]

Using Weierstraß’ equation to discard the \( y_1 \) and \( y_2 \) terms, we obtain

\[
\left((x_1 - x_2)^2(x_1 + x_2 + x) - f(x_1) - f(x_2)\right)^2 = 4f(x_1)f(x_2).
\]

\[ (2) \]
We denote $x = x^{(0)} + \alpha x^{(1)}$ where $x^{(0)}, x^{(1)}$ are in $\mathbb{F}_p$ and where $\alpha$ satisfies $\alpha^2 = \beta$ for some $\beta$ quadratic non-residue modulo $p$, and we denote $x_1 = x^{(0)}_1 + \alpha x^{(1)}_1, x_2 = x^{(0)}_2 + \alpha x^{(1)}_2$ accordingly. Having $x \in \mathbb{F}_p$ implies $x^{(1)} = 0$. Let us denote by $G \in \mathbb{F}_p[Y_1, Y_2, Y_3]$ the polynomial

$$G(Y_1, Y_2, Y_3) = ((Y_1 - Y_2)^2(Y_1 + Y_2 + Y_3) - f(Y_1) - f(Y_2))^2 - 4f(Y_1)f(Y_2).$$

As each $Y_i$ can be expressed as $Y_i = X_{2i-1} + \alpha X_{2i}$ where the $X_j$ variables are over $\mathbb{F}_p$. It follows that there exists a pair of unique polynomials $g_0$ and $g_1$ of $\mathbb{F}_p[X_1 \ldots X_6]$ such that

$$g_0(X_1, \ldots, X_6) + \alpha g_1(X_1 \ldots X_6) = G(X_1 + \alpha X_2, X_3 + \alpha X_4, X_5 + \alpha X_6).$$

Now, for any $x_1, x_2, x \in \mathbb{F}_p^2$ satisfying Equation (2)

$$g_0(x^{(0)}_1, x^{(1)}_1, x^{(0)}_2, \ldots, x^{(1)}_1) + \alpha g_1(x^{(0)}_1, \ldots, x^{(1)}_1) = 0.$$
Taking into account that \(x = x^{(0)} \in \mathbb{F}_p\), we come up with the following polynomial system in five variables:

\[
\begin{align*}
g_0'\left(x_1^{(0)}, x_1^{(1)}, x_2^{(0)}, x_2^{(1)}, x^{(0)}\right) &= g_0\left(x_1^{(0)}, x_1^{(1)}, x_2^{(0)}, x_2^{(1)}, x^{(0)}\right) = 0 \\
g_1'\left(x_1^{(0)}, x_1^{(1)}, x_2^{(0)}, x_2^{(1)}, x^{(0)}\right) &= g_1\left(x_1^{(0)}, x_1^{(1)}, x_2^{(0)}, x_2^{(1)}, x^{(0)}\right) = 0.
\end{align*}
\]

Computing the elimination ideal of \(\langle g_0', g_1' \rangle\), in the variable \(x^{(0)}\), we obtain a polynomial \(f\) of constant degree such that for all \(P_1 = (x_1, y_1), P_2 = (x_2, y_2)\) summing up to \((x, y)\) with \(x \in \mathbb{F}_p\), we have

\[f\left(x_1^{(0)}, x_1^{(1)}, x_2^{(0)}, x_2^{(1)}\right) = 0.\]

**Remark 2.** Speaking in terms of ideal and algebraic varieties, we claim that from the fact that by definition \(\langle \rangle \subseteq V(f)\). It follows that \(V(g_0', g_1') \subseteq V(f)\). Since by construction of \(g_0'\) and \(g_1'\), \((x_1^{(0)}, x_1^{(1)}, x_2^{(0)}, x_2^{(1)}) \in V(g_0', g_1')\), our claim follows.

We are now ready to define the ZJ-Problem, which lies at the heart of our ECDLP algorithm.

**Problem 2 (ZJ-Problem).** Given two lists \(A = (x_A, y_A)\) and \(B = (x_B, y_B)\) in \(\mathbb{F}_p^2\) and a polynomial \(f\) of \(\mathbb{F}_p[X_1, \ldots, X_4]\) compute the list \(C\) of all \((x_A, y_A, x_B, y_B) \in A \times B\) such that \(f(x_A, y_A, x_B, y_B) = 0\).

We claim that any algorithm solving the ZJ-Problem can be used as the main routine to solve Problem 1. Indeed, given our lists \(L_1\) and \(L_2\) respectively of points \(P_1 = (x_1, y_1)\) and \(P_2 = (x_2, y_2)\), and given the polynomial \(f\) defined as above, we compute the list \(A\) of all \((x_1^{(0)}, x_1^{(1)})\) where \(x_1 = x_1^{(0)} + \alpha x_1^{(1)}\). Then we compute the list \(B\) of all \((x_2^{(0)}, x_2^{(1)})\) where \(x_2 = x_2^{(0)} + \alpha x_2^{(1)}\). Now, let us denote by ZeroJoin any algorithm solving the ZJ-Problem. Let \(C = \text{ZeroJoin}(A, B, f)\).

We claim that for every \(P_1, P_2\) satisfying \(P_1 + P_2 = (x, y)\) with \(x \in \mathbb{F}_p\),\(\left(\left(x_1^{(0)}, x_1^{(1)}\right), \left(x_2^{(0)}, x_2^{(1)}\right)\right) \in C\). This comes from the definition of \(f\).

However, there may be false positives — meaning tuples \(\left(\left(x_1^{(0)}, x_1^{(1)}\right), \left(x_2^{(0)}, x_2^{(1)}\right)\right)\) for which \(f(x_1^{(0)} \ldots x_2^{(1)}) = 0\) holds, but \(P_1 + P_2 = (x, y)\) with \(x \notin \mathbb{F}_p\).

Therefore, we need to check the corresponding sum \((x, y)\), while computing the list \(L\). In other words, for all \(\left(\left(x_1^{(0)}, x_1^{(1)}\right), \left(x_2^{(0)}, x_2^{(1)}\right)\right) \in C\), we first retrieve the corresponding \((P_1, P_2) \in A \times B\). Then we compute \((x, y) = P_1 + P_2\). If \(x \in \mathbb{F}_p\), we add \((x, y)\) to \(L\).

This is summarized in Algorithm 3. The following lemma provides a reduction from the ZJ-Problem to Problem 1.
Algorithm 3  \textsc{ECJoin}(E, f, L_1, L_2)

\textbf{Require:} An elliptic curve $E$ over $\mathbb{F}_{p^2}$, two lists of point $L_1$, $L_2$, the polynomial $f$ associated to $E$.

\textbf{Ensure:} $L = \{(P_0, k_1 + k_2) : P_0 = P_1 + P_2 = (x, y), (P_i, k_i) \in L_i, i \in [1, 2], x \in \mathbb{F}_p\}$.

1: $A, B, L \leftarrow \bot$
2: for all $(P_1, k_1) \in L_1$ do
3: \hspace{1em} $A \leftarrow A \cup \{(x_1, x_1^{(1)})_1, k_1\}$, where $P_1 = (x_1, y_1)$
4: for all $(P_2, k_2) \in L_2$ do
5: \hspace{1em} $B \leftarrow B \cup \{(x_2, x_2^{(1)})_2, k_2\}$, where $(x_2, y_2) = P_2$
6: $C \leftarrow \text{ZeroJoin}(A, B, f)$
7: for all $(i, j) \in C$ do
8: \hspace{1em} $(P_i, k_i) \leftarrow L_1[i]$, $(P_j, k_j) \leftarrow L_2[j]$
9: \hspace{1em} $P_0 = (x, y) \leftarrow P_1 + P_2$
10: if $x \in \mathbb{F}_p$ then
11: \hspace{1em} $L \leftarrow L \cup \{(P_0, k_1 + k_2)\}$

\begin{lemma}
If $\text{ZeroJoin}$ solves the $ZJ$-Problem in time $T$ and memory $M$, The $\text{ECJoin}$ algorithm solves Problem 1 in time $T$ and memory $M$.
\end{lemma}

\begin{proof}
Let us denote by $T_{\text{ECJoin}}$ the time complexity of the $\text{ECJoin}$ algorithm. This algorithm consists of three for-loops and the $\text{ZeroJoin}$ procedure. The first for-loop is iterated $|L_1|$ times, and each iteration takes time $O(1)$. The second for-loop is iterated $|L_2|$ times. Once again each iteration requires a constant number of field operations. Then comes the $\text{ZeroJoin}$ procedure which has a runtime $T$. Finally, the last for-loop requires to perform $|C|$ constant time iterations. It follows that:

$T_{\text{ECJoin}} = O(\max(|L_1|, |L_2|, T, |C|))$.

It is clear that $T \geq |C|$, as the list $C$ is built during the $\text{ZeroJoin}$ procedure. We claim that $T$ also satisfies $T \geq |L_1| + |L_2|$, as each of the $|L_1|$ polynomial and each of the $|L_2|$ point have to be considered at least once in order to create $C$. It follows that $T_{\text{ECJoin}} = T$.

Let us focus on the memory. We denote by $M_{\text{ECJoin}}$ the memory required by the $\text{ECJoin}$ procedure. We have:

$M_{\text{ECJoin}} = O(\max(|L_1|, |L_2|, M, |C|))$.

Once again it is clear that $M \geq |C|$. We also claim that $M \geq |L_1| + |L_2|$ as our algorithm requires to store lists $A$ and $B$ of respective size $|L_1|$ and $|L_2|$. It follows that $M_{\text{ECJoin}} = M$.
\end{proof}

We now reduce the $ZJ$-Problem to $p^2$-ECDLP.
Theorem 1. Under our heuristic, if there exists an algorithm ZeroJoin solving the $\mathcal{E}$-Problem in time $T$ and memory $M$, then RepECDLP solves the $p^2\mathcal{E}$-ECDLP problem in time $T$ and memory $M$.

Proof. We start by proving the time complexity. The RepECDLP algorithm consists basically of three steps. In the first step the lists $L_i$ for $i \in \{1, 4\}$ are created using the BuildLists procedure. According to Lemma 2 this can be done in time $O(\max(|L_i|))$. The second step consists in creating both the join of $L_1$ and $L_2$, and of $L_3$ and $L_4$. According to Lemma 3, this takes time $T$. It remains to search for a collision between two lists. This can be done in time proportional to the size of the two lists provided that they are sorted according to the first component. Under our heuristic, we can assume that the points $(x, y)$ contained in the lists are uniformly distributed over $\mathbb{F}_p \times \mathbb{F}_p$, as such the sorting step can be done in time proportional to the size of lists. Recall that $T \geq \max(|L_1|, |L_2|)$ for the same argument than the one given in the proof of Lemma 3. It follows that the time complexity of the whole algorithm is dominated by $T$.

We claim that the memory complexity is dominated by the one of the ECJoin routines. Indeed as explained before, the space $M$ required by this routine is at least $O \left( \max(p^{2+\lambda}, p^{1-\lambda}, |L_1|, |L_2|) \right)$, which is enough to prove our claim.

For completeness, we now prove that this procedure actually solves the $p^2\mathcal{E}$-ECDLP problem. For simplicity, we consider only the first component of the lists elements. By construction

$$
L_i = \begin{cases}
\{k_i P, k_i \in T_i\} & \text{if } i \in \{1, 3\} \\
\{Q - k_i P, k_i \in T_i\} & \text{if } i = 2 \\
\{-k_i P, k_i \in T_i\} & \text{if } i = 4.
\end{cases}
$$

We claim that $L = \text{ECJoin}(L_1, L_2)$ is the list

$$L = \{k_12 P = (x, y), k_12 \in S_1, x \in \mathbb{F}_p\}. \quad (3)$$

Indeed, by construction, it is obvious that $\forall (x, y) \in L$, $x \in \mathbb{F}_p$. Furthermore $(x, y) = k_2 P$ for some $k_2 \in S_1$ as $(x, y) = k_1 P + k_2 P = (k_1 + k_2)P$ for some $(k_1, k_2) \in L_1 \times L_2$. It follows that $L \subseteq \{k_12 P = (x, y), k_12 \in S_1, x \in \mathbb{F}_p\}$. We show that this is indeed an equality.

Recall that $f \in \mathbb{F}_p[X_1, X_2, X_3, X_4]$ is constructed so that, for all points $P_1 = (x_1, y_1), P_2 = (x_2, y_2) \in E(\mathbb{F}_p^2)$, if $(x, y) = P_1 + P_2$ satisfies $x \in \mathbb{F}_p$, then $f(x_1^{(0)}, x_1^{(1)}, x_2^{(0)}, x_2^{(1)}) = 0$. Now for any $P_i = (x_i, y_i)$, let us consider the polynomial $f_i \in \mathbb{F}_p[X, Y]$ such that $f_i(X, Y) = f(x_i^{(0)}, x_i^{(1)}, X, Y)$. It is clear that, for all $P_j = (x_j, y_j)$ such that $P_i + P_j = (x, y)$ with $x \in \mathbb{F}_p$, $f_i(x_j^{(0)}, x_j^{(1)}) = 0$. As $A$ is the set of the $f_i$ polynomials for all $(x_i, y_i) \in L_1$, and $B$ is the set of the $(x_j^{(0)}, x_j^{(1)})$ tuples for all $(x_j, y_j) \in L_2$, it follows, from the definition of the ZeroJoin procedure, that if $P_i + P_j = (x, y)$ satisfies $x \in \mathbb{F}_p$, then $(i, j) \in C = \text{ZeroJoin}(A, B)$. As such $\{k_12 P = (x, y), k_12 \in S_1, x \in \mathbb{F}_p\} \subseteq \{P_i + P_j, (i, j) \in C\}$, only those points which indeed satisfy $x \in \mathbb{F}_p$ are kept in
\[ L' = \{ Q - k_{34}P = (x', y'), \ k_{34} \in S_2, \ x \in \mathbb{F}_p \}. \]

It remains to show that a representation \((k_{12}, k_{34})\) of our solution \(k\) is contained in the list \(L \times L'\). We argue that our algorithm succeeds in solving \(p^2\)-ECDLP if there is a representation \((k_{12}, k_{34}) \in S_1 + S_2\) of \(k\) such that \(k_{12}P = (x, y)\) with \(x \in \mathbb{F}_p\).

It is clear that if there is no such representation of \(k\) our procedure fails, as only \(k_{12} \in S_1\) for which \(k_{12}P = (x, y)\) with \(x \in \mathbb{F}_p\) are considered. Now, if such a \(k_{12}\) exists, according to Equation 3, \(k_{12}P\) is in \(L\). Similarly, if \(k_{34}\) satisfies that \(Q - k_{34}P = (x', y')\) with \(x' \in \mathbb{F}_p\), then \(k_{34}\) is in \(L'\). Furthermore, as \(k_{12}P = Q - k_{34}P\), it is enough to know that \(k_{12}\) satisfying \(k_{12}P = (x, y)\) with \(x \in \mathbb{F}_p\) exists, to ensure that the algorithm recovers the solution.

We also claim that if the elements of \(E(\mathbb{F}_p)\) are uniformly distributed (as we assume by our heuristic), then on expectation, there exists a representation \((k_{12}, k_{34})\) which satisfies \(k_{12}P = (x, y)\) with \(x \in \mathbb{F}_p\). First note that the uniform distribution implies

\[ \mathbb{P}[x \in \mathbb{F}_p | (x, y) = \ell P, \ell \in S_1] = \mathbb{P}[x \in \mathbb{F}_p] = \frac{1}{p}. \]

We denote by \(N_{rep}\) the number of representation of \(k\) as the sum \(k_{12} + k_{34}\), \(k_{12} \in S_1, k_{34} \in S_2\). In other words \(N_{rep}\) is the number of elements \(k_{12} \in S_1\) such that there exists \(k_{34} \in S_2\), with \(k_{12} + k_{34} = k\). We denote by \(Y\) the number of surviving representations in \(L + L'\). In other words, \(Y\) is the number of \(k_{12} \in S_1\) such that there exists \(k_{34} \in S_2\) with \(k_{12} + k_{34} = k\), and such that \(k_{12}P = (x, y)\) with \(x \in \mathbb{F}_p\). By Lemma 1, we have

\[ \mathbb{E}[Y] = N_{rep} \frac{1}{p} > \frac{r}{p^2}. \]

By Hasse’s theorem, \(r \geq p^2 - 2p\) and therefore for sufficiently large \(p\) we expect that one representation survives. \(\square\)

4 Solving the ZJ-Problem

The running time of our new \(p^2\)-ECDLP algorithm is dominated by solving the ZJ-Problem. Recall that in the ZJ-Problem we are given two lists \(A\) and \(B\) consisting respectively of \(N\) points \((x_{11}, y_{11}) \ldots (x_{1N}, y_{1N}) \in \mathbb{F}_p^2\) and \(M\) points \((x_{21}, y_{21}) \ldots (x_{2M}, y_{2M}) \in \mathbb{F}_p^2\), and a polynomial \(f\) for which we have to find all roots \((x_{1i}, y_{1i}), (x_{2j}, y_{2j})\) in our lists, that is \(f(x_{1i}, y_{1i}, x_{2j}, y_{2j}) = 0\).

Naively, we can solve the ZJ-Problem in time \(T = \mathcal{O}(NM)\). Namely, from the first list \(A\) of points \((x_i, y_i)\) we construct a list \(A\) of bivariate polynomials

\[ f_i(X, Y) = f(x_{1i}, y_{1i}, X, Y). \]
Then we successively evaluate all \( f_i(X, Y) \) in all \( M \) points \((x_1, y_1) \ldots (x_M, y_M) \in \mathbb{F}_p^2\) from the second list \( B \). As each polynomial has constant degree, each of the \( NM \) evaluations costs time \( \mathcal{O}(1) \). As a result we obtain a list \( C \) of all the \((f_i, (x_j, y_j)) \in \bar{A} \times B\), such that \( f_i(x_j, y_j) = 0 \). Since we have \( NM = p^2 \), this gives us an ECDLP algorithm with run time \( \mathcal{O}(p^2) \).

**Fast Polynomial multiplication.** Let \( I \subset [1, M] \). Obviously, if

\[
F_I(X,Y) = \prod_{i \in I} f_i(X,Y) = 0,
\]

then there is an \( i \in I \) with \( f_i(x, y) = 0 \). This gives rise to the following algorithm.

1. Partition the set \( A \) of polynomials into buckets \( A_{I_1}, A_{I_2}, \ldots A_{I_k} \), for some \( k \geq 1 \), such that \( f_i \in A_{I_i} \) iff \( i \in I_i \).
2. For each \( I_i \), compute the set \( B_{I_i} \) of points \( (x_j, y_j) \in B \), such that \( F_{I_i}(x_j, y_j) = 0 \).
3. For each \( f_i \in A_{I_i} \), find all \((x_j, y_j) \in B_{I_i}\), such that \( f_i(x_j, y_j) = 0 \).

Our solution uses fast bivariate polynomial multi-point evaluation, that has on optimal choice \( N = \sqrt{p}, M = p \), for which only a single \( F_I = F \) has to be computed. This special case is given in Algorithm 4. The following multi-point evaluation result is due to Niüksen and Ziegler [NZ04].

**Lemma 4 ([NZ04, Result 4]).** For any fixed \( \epsilon > 0 \), a bivariate polynomial \( f \in \mathbb{F}_p[X,Y] \) of degree in \( X, Y \leq d \), specified by its coefficients, can be evaluated simultaneously at \( M \) given points \((x,y) \in \mathbb{F}_p^2\), with pair-wise different \( x \)-coordinates using \( \mathcal{O} \left( (M + d^2)\omega^{-1+\epsilon} \right) \) operations in \( \mathbb{F}_p \), where \( \omega_2 \leq 3.257 \) is the exponent of \( n \times n \) by \( n \times n^2 \) matrices multiplications.

**Algorithm 4 MultiEval(\( \bar{A}, B \)).**

**Require:** A list \( A \) of \( \sqrt{N} \) polynomials of \( \mathbb{F}_p[X,Y] \) and a list \( B \) of \( p \) points of \( \mathbb{F}_p^2 \).

**Ensure:** The list \( C \) of all the \((f_i, (x_j, y_j)) \in \bar{A} \times B \) such that \( f_i(x_j, y_j) = 0 \).

1. \( B', C \leftarrow \perp \)
2. \( F \leftarrow \prod_{i=1}^{\sqrt{p}} f_i \)
3. \( E \leftarrow \text{BivariatePolynomialMultipointEvaluation}(F, B) \)
4. for all \( 1 \leq j \leq p \): \( E[j] = 0 \)
5. \( B' \leftarrow B' \cup \{(x_j, y_j)\} \)
6. for all \( f_i \in \bar{A} \)
7. for all \((x_j, y_j) \in B' \)
8. if \( f_i(x_j, y_j) = 0 \) then
9. \( C \leftarrow C \cup (f_i, (x_j, y_j)) \)

**return** \( C \)

We make use of the Schwartz-Zippel Lemma, from which we derive an upper bound on the number of zeroes of \( F \) in \( B \) in Algorithm 4.
Lemma 5 (Schwartz-Zippel). Given a polynomial $F \in \mathbb{F}_p[X,Y]$ of degree at most $d$ in $X,Y$, a random point $(x,y) \in \mathbb{F}_p^2$ is a zero of $F$ with probability

$$\mathbb{P}[F(x,y) = 0] \leq \frac{d}{p}.$$ 

Theorem 2. RepECDLP in combination with MultiEval solves $p^2$-ECDLP in time $T = \tilde{O}(p^{1.314})$.

Proof. We start by showing that the time complexity of MultiEval is dominated by the bivariate polynomial multi-point evaluation line 3. At this aim, we denote by $T_F$, $T_E$, $T_{B'}$, and $T_C$ respectively the time complexity required to compute $F$ at line 2, to perform the multi-point evaluation at line 3, to execute the for-loop in line 4 and to execute the for-loop in line 6. The total runtime of the MultiEval procedure is given by

$$T = \max(T_F, T_E, T_{B'}, T_C). \tag{4}$$

First we estimate $T_F$. Notice that the degree of $F$ in $X$ and in $Y$ is bounded by a constant $c$ times $\sqrt{p}$, since $F$ is the product of $\sqrt{p}$ polynomials of constant degree in $X$ and $Y$. It follows that $F$ can be computed in $T_F = \tilde{O}(p)$ operations, using fast polynomial multiplication algorithms, where logarithmic factors are hidden in the $\tilde{O}$.

Next, we have to evaluate this polynomial simultaneously in all the $p$ points. From Lemma 4, this takes time $O\left(p^{\frac{1}{2}(1+\omega^2)+\epsilon}\right)$ for any fixed $\epsilon > 0$.

There is a small twist, however as lemma 4 can only be applied for a list of points $(x,y)$ with pair-wise different $x$-coordinates. Considering that all $x$ are in $\mathbb{F}_p$ and that $|B| = p$, this condition implies that all elements of $\mathbb{F}_p$ are present once and only once as the $x$-coordinate of an element of $B$. This is very unlikely. In fact, we proceed as follows. We partition $B$ according to the $x$-coordinate and apply the Nüsken-Ziegler algorithm with one element of each partition of $B$. We restart until all elements of each partitions have been processed.

The number of time we have to restart is bounded by the size of the largest partition of $B$. If the $x$-coordinated are uniformly distributed over $\mathbb{F}_p$, we can estimate this size, using maximum-load results [Mit96]. We obtain that the number of time we have to restart is with high probability bounded by a constant times $\frac{\log p}{\log \log p}$. Replacing $\omega_2$ by the best known bound 3.257 [LG14], and for $\epsilon < 10^{-4}$, its follows that $T_E = \tilde{O}(p^{1.314})$.

We may assume that for each evaluated value $E[j]$ we kept track of the corresponding $(x_j, y_j)$. Then building $B'$ from $E$ requires only to scan through each entry of $E$ once, and add $(x_j, y_j)$ in $B'$ for all $E[j] = 0$ that are encountered. The runtime of this step is thus linear in $|E| = |B|$, and therefore $T_{B'} = \mathcal{O}(p)$.

The last step consists in evaluating all $f_i$ simultaneously in all the point of $B'$. We proceed in a naive way by taking all the polynomials, one by one, and evaluating each of them simultaneously in all the point of $B'$. This results in the two entwined for-loops in line 6 and 7. The first one iterates over all the polynomials and thus is iterated $\sqrt{p}$ times. The second one iterates over all the
points of $B'$ and thus is iterated $|B'|$ times. Each iteration of the second loop can be performed in $O(1)$ as all the $f_i$ are of constant degree. It follows that $T_C = O\left(\sqrt{p}|B'|\right)$.

It remains to estimate $|B'|$. From Lemma 5, for any random $(x, y) \in F_p^2$

$$\mathbb{P}[F(x, y) = 0] \leq \frac{\sqrt{p}}{p}.$$  

Assuming that the points of $B$ are uniformly distributed over $F_p^2$, it follows that the expected size $Z$ of $B'$ satisfies

$$\mathbb{E}[Z] = \sqrt{p},$$  

and thus the expected time complexity of this third step is $O(p)$. From Equation 4, it follows that

$$T = O\left(\max(p, p^{1.314})\right) = O\left(p^{1.314}\right).$$  

Building the list $\bar{A}$ of the polynomials $f_i$ from the list $A$ of points $(x_i, y_i)$ and the polynomial $f$ can be done in time linear in $|A| = \sqrt{p}$, since $f$ has constant total degree. Thus the ZJ-Problem can be solved in time $T$ too. From Theorem 1, we can conclude that $\text{RepECDLP}$ solves $p^2\text{-ECDLP}$ in time $O\left(p^{1.314}\right)$. \hfill \Box

We hope that the result of Theorem 2 may be further improved. A possible direction is to replace the (unnecessary) multi-evaluation of $F$ by some presumably more efficient zero testing method. An other research direction, as pointed out by one of the reviewers, could be to have a look at a different elliptic curve model than the one of Weierstraß (e.g. Edwards Curve). However, we are not sure whether the problem would become easier in this case.

**Acknowledgement** The authors would like to thank the reviewers for their comments, as well as Andre Esser for proof reading this paper.
