Abstract

We investigate the propagation modes of gauge fields in an infinite Randall-Sundrum scenario. In this model a sine-Gordon soliton represents our thick four-dimensional braneworld while an exponentially coupled scalar acts for the dilaton field. For the gauge-field motion we find a differential equation which can be transformed into a confluent Heun equation. By means of another change of variables we obtain a related Schrödinger equation with a family of symmetric rational \((\gamma - \omega z^2)/(1 - z^2)^2\) potential functions. We discuss both results and present the infinite spectrum of analytical solutions for the gauge field. Finally, we assess the existence and the relative weights of Kaluza-Klein modes in the present setup.

Keywords: Extra-dimensions, Sine-Gordon, Dilaton, Kaluza-Klein,
I. INTRODUCTION

One of the main purposes of superstring theory is the inclusion of all the relevant fields of Nature together in one single Lagrangian. Field theoretic scenarios inspired in such a theory put in contact gauge and matter fields with metric degrees of freedom, altogether defined in some extra-dimensional space [1]. Extra-dimensions, combined with the influence of the gravitational field, modify nontrivially all sectors so that gauge forces must be proven to remain the same in the usual four-dimensional (4D) subspace or predict new physics in some consistent way. Localization in the gauge sector is expected to hold and the effective 4D electromagnetic force must be mediated by massless photons as usual. On the other hand, higher-dimensional spaces help solving fundamental problems such as the hierarchy gap between the Planck and gauge-coupling scales in the Standard model [2].

Also inspired in String theory is the use of branes to represent our Universe. In String theory, gauge modes are deposited on D-branes from open strings ending on them, so we expect gauge fields in field-theoretic models to have finite localized modes on stringy topological defects of lower dimensionality. Actually, to obtain finite eigenstates in 4D it has been shown that to fulfill this task we need not just gravity but also a dilaton [3, 4], a field already predicted in String theory.

In the present paper, we describe gauge fields in a warped five-dimensional bulk with a dilaton and a brane defect that mimics the ordinary world. Both brane and dilaton configurations are geometrically consistent solutions of a two scalar world action in a curved 5D space-time where the field potential is of sine-Gordon type.

We show a relationship between the fundamental parameters of the 5D theory which is crucial to determine the dynamics of the fields both in the bulk and ordinary space. Indeed, for different choices of a parameter defined by the quotient of some power of the sine-Gordon frequency-amplitude and the 5D Planck mass, the equations of motion of the gauge field can be completely different. Notably, in Ref. [5] we have been able to find the whole spectrum of a theory involving both Maxwell and Kalb-Ramond fields for a particular value of this parameter. As we will see, there exists a minimal value for the dilaton coupling constant above which the finiteness of the action is assured and it is directly related to the localization of gauge fields.

In what follows we analytically obtain the propagation modes (massless and massive) of
a gauge theory in a background of the sine-Gordon type that results in new equations of motion. We show that the dynamics of the quantum mechanical system associated with the problem is given by a simple (rational) potential function and that the solutions to the Schrödinger equation are of the Mathieu type (with a power-law factor). In a more general case we obtain the exact spectrum given by the set of confluent Heun functions and show that Kaluza-Klein states are strongly suppressed in ordinary space.

The paper is organized as follows. In the next Section, we present the geometrical background. In Section III we introduce the action for the 5D gauge field coupled to warped gravity and a dilaton background and derive the 5D equations of motion. In Section IV we obtain the quantum analog problem showing explicitly the quantum-mechanical Schrödinger potential. The eigenvalue spectrum is computed and graphically shown. Next, in Sections V and VI we discuss the general problem and draw our conclusions. Other recent results about thick braneworlds can be found in e.g. [6].

II. GEOMETRICAL BACKGROUND

Our framework is a five-dimensional space-time embedding a four-dimensional membrane also called thick brane. The (space-like) extra-dimension is assumed infinite and the brane will be dynamically obtained as a solution to the Einstein equations for gravity coupled to a pair of scalar fields. One of these scalars represents a domain wall defect (the thick brane) while the other is the dilaton. The dilaton, together with the warping of the fifth dimension, happens to be crucial in the gauge theory that will be developed and makes more clear the stringy origin of the theory. Since gauge field theory is conformal [7] all the information coming from the warping of the 4D metric is automatically lost. As a consequence the photon is non-normalizable in the four-dimensional space unless the gauge coupling is dynamically modified. Indeed, the exponential coupling of both the dilaton and the 5D warping to the gauge field conveniently modifies the scaling properties and the zero-mode becomes localized [3].

The five-dimensional world action which determines the background is

\[ S_B = \int d^5x \sqrt{- \det G_{MN}} \left[ 2M^3R - \frac{1}{2} (\partial \Phi)^2 - \frac{1}{2} (\partial \Pi)^2 - V(\Phi, \Pi) \right], \tag{1} \]

where \( M \) is the Planck mass in 5D, and \( R \) is the Ricci scalar. The solution for \( \Phi \) represents the...
world membrane and the corresponding field solution for $\Pi$ will be the dilaton configuration consistent with the metric and the kink. As usual we adopt Latin capitals on the bulk and Greek lower case letters on 4D.

We next adopt the following ansatz for the metric

$$ds^2 = e^{2\Lambda(y)} \eta_{\mu\nu} dx^\mu dx^\nu + e^{2\Sigma(y)} dy^2,$$

where $\Lambda$ and $\Sigma$ depend just on the fifth coordinate, $y$, and $\text{diag}(\eta) = (-1, 1, 1, 1)$. The equations of motion for eq. (1) are

$$\frac{1}{2}(\Phi')^2 + \frac{1}{2}(\Pi')^2 - e^{2\Sigma(y)} V(\Phi, \Pi) = 24M^3(\Lambda')^2,$$

$$\frac{1}{2}(\Phi')^2 + \frac{1}{2}(\Pi')^2 + e^{2\Sigma(y)} V(\Phi, \Pi) = -12M^3 \Lambda'' - 24M^3(\Lambda')^2 + 12M^3 \Lambda' \Sigma',$$

and

$$\Phi'' + (4\Lambda' - \Sigma')\Phi' = e^{2\Sigma} \frac{\partial V}{\partial \Phi},$$

$$\Pi'' + (4\Lambda' - \Sigma')\Pi' = e^{2\Sigma} \frac{\partial V}{\partial \Pi},$$

where the prime means derivative with respect to $y$.

By means of a supergravity motivated functional $W(\Phi)$ defined by

$$\Phi' = \frac{dW}{d\Phi}$$

the system of differential equations can be more easily handled. This method is also applicable to non-supersymmetric domain walls [9, 10] as the present one.

First, we consider the action in the absence of gravity (and no dilaton) in order to obtain an expression for $\Phi$. Then, we put this solution into the equations of motion (3) and (4).

The standard sine-Gordon Lagrangian reads

$$L_{SG} = -\frac{1}{2} \partial^2 \Phi - V(\Phi)$$

with

$$V(\Phi) = \frac{1}{b^2} (1 - \cos(b \Phi)).$$

The free parameter $b$ signals bulk-symmetries $\delta \Phi \to 2n\pi/b$ ($n \in Z$) among the vacua of this theory. Solutions interpolating vacua are possible and, assuming they depend only on $y$, one-solitons read

$$\Phi(y) = \frac{4}{b} \arctan e^y.$$
These functions kink on our 4D-world slice, namely at $y \sim 0$.

In a gravitational background of the form (2), now including also the dilaton, the equations of motion (3) and (4) are still compatible with solutions (7) provided we find the appropriate potential functional $V$ for the general action (1), viz.

$$V(\Phi, \Pi) = \exp \left( \frac{\Pi}{\sqrt{12M^3}} \left( \frac{1}{2} \frac{dW}{d\Phi} \right)^2 - \frac{5}{32M^3} W(\Phi)^2 \right).$$

Taking into account eq.(5), the superpotential functional results

$$W(\Phi) = -\frac{4}{b^2} \cos \left( \frac{b}{2} \Phi \right)$$

and then

$$V(\Phi, \Pi) = -e^{\left( \frac{\Pi}{\sqrt{12M^3}} \right)} \left( \frac{4}{b^2} \sin^2 \frac{b}{2} \Phi + \frac{5}{2M^3b^4} \cos^2 \frac{b}{2} \Phi \right).$$

If we now conveniently write the Hamiltonian à la Bogomol’nyi, we can detect the following relations among the warping functions, the dilaton and the superpotential

$$\Pi = -\sqrt{3M^3} \Lambda, \quad \Sigma = \Lambda/4, \quad \Lambda' = -W/12M^3.$$ 

Finally, totally solving the equations of motion, the dilaton field is given by

$$\Pi(y) = \frac{1}{\sqrt{3M^3b^2}} \ln \cosh y,$$

and

$$\Lambda = -\frac{1}{3M^3b^2} \ln \cosh y, \quad \Sigma = -\frac{1}{12M^3b^2} \ln \cosh y.$$

The relation between $\Pi$ and $\Phi$ allows also writing $V$ as

$$V(\Phi) = -\frac{4}{b^2} \left( \sin \frac{b}{2} \Phi \right)^{1/6M^3b^2} \left( 1 + \left( \frac{5}{8M^3b^2} - 1 \right) \cos^2 \frac{b}{2} \Phi \right),$$

which fully shows its dependence on $b$ and $M$ (see Fig. 1).

As it happens with dilaton configurations related to D-brane solutions, functions such as (7) and (12) are singular when $|y| \to \infty$. However, since the metric vanishes exponentially and both dilaton and warp factors operate under an exponential coupling, the model is kept free of divergences.

The warping functions amount to a shift in the effective four-dimensional Planck scale, which remains finite with the following definition

$$M_P^2 \equiv M^3 \int_{-\infty}^{\infty} dy \ e^{4\Lambda(y) + \Sigma(y)}.$$
Figure 1. Family of background potential functionals $V(\Phi)$ (eq.14) for different values of $a \equiv 1/6M^3b^2$: even $a = 2, 4, 6, 8, 10$ (solid line), odd $a = 1, 3, 5, 7, 9$ (dashed line). For clarity we adopted thinner lines for bigger values of $a$.

Using the consistency relation (11) just found, the action reads

$$S_B \sim \int dy \ e^{4\Lambda(y) + \frac{1}{2}\Lambda(y) + \frac{1}{2}\sqrt{3M^3}\Lambda(y)} \ S_{(4)}$$

where $S_{(4)}$ is the remaining of the action integrated in 4D. According to the solution $\Lambda(y) = 2a \ln \text{sech}y$ (c.f. eq.11 - eq.13) the 5D factor results finite provided $c \equiv (17 + 2\lambda\sqrt{3M^3})/4 > 0$, namely $\lambda > -\frac{17}{2\sqrt{3M^3}} = \lambda_0$.

Studying the fluctuations of the metric about the above background configuration, it is possible to see that this model supports a massless zero-mode of the gravitational field localized on the membrane even in the presence of the dilaton. In order to prove the stability of the background solution, we would have to show that there are no negative mass solutions to the equations of motion of a perturbation $h_{\mu\nu}$ of the metric. Actually, a gravitational Kaluza-Klein spectrum appears, starting from zero and presenting no gap. This can be easily seen after an appropriate change of variables and decomposition of the gravitational field, and a subsequent supersymmetric type expression of the Schrödinger type operator resulting from the equation of motion (see [3, 11] for details). The issue of the coupling of these massive modes to the brane has been analyzed in detail in [12].
III. GAUGE FIELD ACTION IN A WARPED SPACE WITH DILATON

Let us consider the following 5D action where a five-dimensional electromagnetic field $A_N$ is coupled to the dilaton in a warped space-time

$$S_g = \int dy dx \sqrt{-\det G_{AB}} e^{-\frac{\lambda}{2} \Pi} \left\{ -\frac{1}{4} F_{MN} F^{MN} \right\}$$

where $F_{MN} = \partial_M A_N$.

Assuming that the gauge field energy density should not strongly modify the geometrical background, we can study the behavior of the propagating modes in the background of the topological configuration studied in the last Section. In general, most of the attempts to stabilize 5D brane worlds by means of a scalar field in the bulk do not take into account the back-reaction of the scalar field on the background metric and those in order to compute the scalar back-reaction on the metric were unsuccessful except in a few special cases.

The factor $\exp(\Sigma - \lambda \Pi/2)$, present in the integrand, will lead to a change in the integration measure which is crucial to conserve the effect of the warping function on the 4D gauge field. As a consequence, zero-modes (namely photons) are normalizable in the 4D effective theory. To see it in detail, we need to solve the 5D equations of motion for $A_M$

$$\frac{1}{\sqrt{-G}} \partial_M (G^{MR} G^{NP} F_{RP} \sqrt{-G} e^{-\frac{\lambda}{2} \Pi(y)}) = 0$$

where $\text{diag } G_{MN} = (e^{2\Lambda} \eta_{\mu\nu}, e^{2\Sigma})$. For this, we adopt the following gauge choice $A^5 = 0$, $\partial_{\mu} A^\mu = 0$ and separate the fifth from the ordinary coordinates as follows

$$A^\mu(x, y) = a^\mu(x) u(y).$$

Now, from eq. (18) we just get

$$[\Box + \frac{1}{u} f \partial_5 (f \partial^5 u)] a^\mu = 0.$$ 

Note that the warped metric and the dilaton deform the solutions of this differential equation by means of the factor $f(y) \equiv e^{4\Lambda + \Sigma - \lambda \Pi/2}$ multiplying $u(y)$ and $u'(y)$. A full Kaluza-Klein spectrum results from the solution of the general case

$$\partial_5 (f \partial^5 u) = -m^2 f u,$$
where $m^2$ is an arbitrary constant representing the 4D squared boson mass of the vector gauge field. It means that $a^\mu = a^\mu(0)e^{ipx}$ with $p^2 = - m^2$.

By expanding eq. (20), we obtain the most general $y$-dependent equation of motion for the modified sine-Gordon potential (14) derived from action (17) in a form which exhibits its dependence on $a = 1/6M^3b^2$, and

$$u''(y) + a(1 - 2c) \tanh y \ u'(y) + m^2 \sech^a y \ u(y) = 0,$$  \hspace{0.5cm} (22)

where $y \in (-\infty, \infty)$ as already stated. Looking back at the definition of the auxiliary constants we get the explicit dependence of the solutions on the original parameters $b$, $\lambda$ and $M$.

Below, we will discuss the possible values of $m^2$ as resulting from an eigenvalue problem related to the equation of motion (22). Indeed, there exists a Schrödinger like equation equivalent to eq. (22) with a potential function which concentrates all the richness implicit in the complicated equation (22). Note that the particular solution $u(y) = \text{constant}$ represents the $m^2 = 0$ photon state of the 5D theory. Since this solution satisfies eq. (22) for any value of $a$ and $c$, any member of the family of problems has a guaranteed localized zero-mode. See [5] for details.

Localization of gauge-field modes in the ordinary space can be established by verifying that the corresponding 5D action is finite. From eq. (19) one has $F^{\mu \nu} = f^{\mu \nu}u(y)$, where $f^{\mu \nu} = G^{\mu \alpha}G^{\nu \beta}f_{\alpha \beta}$, so that for a gauge mode $A^{\text{sol}}_M$ the relevant part of eq. (17) reads

$$S_g[A^{\text{sol}}_M] = \int dy \ u^2(y)e^{4\Lambda(y) + \Sigma(y) - \lambda \Pi(y)/2} \int d^4x \ \frac{1}{4} f_{\mu \nu} f^{\mu \nu}.$$  \hspace{0.5cm} (23)

Using the field solutions found in eq. (7) and the equations thereafter, the fifth dimension factor will remain finite for each mode $u(y)$ growing below $e^{ac}$ at infinity. Thus, any finite solution is a physically acceptable Kaluza-Klein state (as we have seen above, to have a finite 5D Planck mass and background action $S_B$ we already need $c > 0$, i.e. $\lambda > \lambda_0$).

It is known that by means of a transformation

$$u(y) = e^{-\alpha \Lambda/2} U(z), \quad \frac{dz}{dy} = e^{-\beta \Lambda}$$  \hspace{0.5cm} (24)

we can turn eq. (22) into a Schrödinger-like equation in the variable $z$ (see e.g. [2, 3]). In general, the existence of an analog Schrödinger equation is useful to give us a feeling of the
physical profile of the solutions of the original problem, as e.g. parity and eigenvalues. With \( \alpha = c - 1/4 \) and \( \beta = -1/4 \) we can eliminate the first derivative term in \( U \) and have a pure mass term as usual. The resulting differential equation reads precisely

\[
\left[ -\frac{d^2}{dz^2} + \mathcal{V}_a(z) \right] U(z) = m^2 U(z),
\]

where \( \mathcal{V}_a(z) = e^{-\Lambda/2}(\frac{\alpha}{2} \Lambda'' - \gamma \Lambda'^2) \) and \( \gamma = \frac{1}{4} \alpha(\frac{1}{2} - \alpha) \). In a few cases the last expression can be inverted after exact integration in order that an analytical expression for the analog non-relativistic potential comes about. In Ref. [5] we have solved the \( a = 2 \) case and found

\[
\mathcal{V}_2(z) = -2\alpha \left[ 1 - (2\alpha - 1) \tan^2 z \right].
\]

In this paper, for \( a = 4 \) we find

\[
\mathcal{V}_4(z) = \frac{(\gamma - \omega z^2)}{(1 - z^2)^2},
\]

where \( \gamma \) and \( \omega \) are constants and we shall analyze it in what follows.

**IV. THE QUANTUM ANALOG**

In the present case we can turn eq. (22) into a Sturm-Liouville problem by means of

\[
z = \tanh y,
\]

\[
u(y) = (\cosh y)^{4c-1} U(z)
\]

(see eq. (24)). Now, we have a related Schrodinger equation defined in the \( z \) variable

\[
\left[ -\frac{d^2}{dz^2} + \mathcal{V}_4(z) \right] U(z) = m^2 U(z),
\]

with

\[
\mathcal{V}_4(z) = \frac{1 - 4c}{(1 - z^2)^2} \left[ 1 + 2(1 - 2c)z^2 \right].
\]

We can see that the potential function diverges at \( z = \pm 1 \) and so the boundary conditions of this analog problem are \( \{ U(z = \pm 1) = 0, \ U''(z = \pm 1) \text{ finite} \} \) which must be in order to match finite \( u(y) \) solutions to eq. (22) at \( y \to \pm \infty \). After solving the quantum analog we have to transform back variables and functions to check the finiteness and continuity of the original solution \( u(y) \) in order to be physically acceptable.
We now better introduce the variable $\theta$ by means of

$$z = \cos \theta$$

which results in equation

$$U''(\theta) - \cot(\theta) U'(\theta) - \frac{1 - 4c}{\sin^2 \theta} \left[1 + 2(1 - 2c) \cos^2 \theta\right] U(\theta) = -m^2 \sin^2 \theta U(\theta)$$

for the analog wave function $U(\theta)$ with $U(\theta = \pi, 0) = 0$.

According to the arguments of localization seen in the previous section, physically acceptable solutions require $c > 0$ so we shall be restricted to that region.

1. The $c=1/4$ case

Equation (30) gets strongly simplified for the value $c = 1/4$. In this case we obtain

$$\frac{1}{\sin \theta} \frac{d}{d\theta} \left( \frac{1}{\sin \theta} U'(\theta) \right) + m^2 \sin^2 \theta U(\theta) = 0$$

with solutions

$$U^{(1)}(\theta) = U_0 \sin(m \cos(\theta))$$

$$U^{(2)}(\theta) = U_0 \cos(m \cos(\theta)),$$

which in terms of the original variable and function read

$$u^{(1)}(y) = u_0 \sin(m \tanh y)$$

$$u^{(2)}(y) = u_0 \cos(m \tanh y),$$

(see Figs. 2, 3). The zero-mode, $m = 0$, is then related to $u(y) = u_0$ as already mentioned.

Since $\Phi(z)$ is an even function (in this case trivial), solutions must have definite parity. Besides, the potential divergence at $z = \pm 1$ implies that the corresponding solutions are expected to be zero there. Thus, antisymmetric solutions correspond to the eigenvalues of the Schrodinger equation (27) $m = n\pi$ while symmetric solutions correspond to $m = (2n+1)\pi/2$, with $n \in \mathbb{N}$ (or simply $m = (n+1)\pi/2$ with $n$ even for symmetric solutions and odd for the antisymmetric ones).
Figure 2. Plot of \( \sin(m \tanh(y)) \), for \( c = 1/4, \ m = \pi \) (black line), \( m = 2\pi \) (long-dashed blue line), and \( m = 3\pi \) (dashed red line).

Figure 3. Plot of \( \cos(m \tanh(y)) \), for \( c = 1/4, \ m = \pi/2 \) (black line), \( m = 3\pi/2 \) (long-dashed blue line), and \( m = 5\pi/2 \) (dashed red line).

2. Other analytical solutions

If we perform the transformation

\[ U(\theta) = \sin^{\kappa} \theta \mathcal{M}(\theta), \tag{36} \]

in place of eq.(30) we get the following problem for \( \mathcal{M}(\theta) \)

\[
\mathcal{M}''(\theta) + (2\kappa - 1) \cot(\theta) \mathcal{M}'(\theta) + \left[ \kappa(\kappa - 2) \cot^2(\theta) - \kappa + \frac{1 - 4c}{\sin^2\theta} \left[ 1 + 2(1 - 2c) \cos^2\theta \right] \right] \mathcal{M}(\theta) = -m^2 \sin^2\theta \mathcal{M}(\theta). \tag{37}
\]

Now, we can choose a convenient power for the last transformation, \( \kappa = 1/2 \), in order to
turn this into

$$M''(\theta) - 4 \left[ \cot^2(\theta) \left( 4c^2 - 4c + \frac{15}{16} \right) + \frac{3}{8} - c \right] M(\theta) = -m^2 \sin^2 \theta M(\theta) \quad (38)$$

which, for $4c^2 - 4c + \frac{15}{16} = 0$, is known as the Mathieu differential equation

$$M''(\theta) + \left( 4c - 3/2 + m^2 \sin^2 \theta \right) M(\theta) = 0, \quad (39)$$

with $c = 3/8$ or $c = 5/8$.

3. The case $c = 5/8$

In this case, Eq. (39) results in

$$M''(\theta) + \left( 1 + \frac{m^2}{2} - \frac{m^2}{2} \cos(2\theta) \right) M(\theta) = 0 \quad (40)$$

whose analytic solutions are the general Mathieu functions

Table I. List of the first 21 values of $m_s$ (symmetric solutions) and $m_a$ (antisymmetric ones) for $c = 5/8$

... ...
Figure 4. Symmetric and antisymmetric eigenfunctions $U$ in $z$ space for $c = 5/8$; $m = 0$ (black line, symmetric), $m = 2.380795874$ (dashed blue line, anti-symmetric), $m = 4.0649860$ (long-dashed red line, symmetric), $m = 5.6914019$ (dotted black line, antisymmetric), and $m = 7.2962115$ (solid green line, symmetric).

\[ M^{(1)}(\theta) = Mc \left( 1 + \frac{m^2}{2}, \frac{m^2}{4}, \theta \right) \tag{41} \]

\[ M^{(2)}(\theta) = Ms \left( 1 + \frac{m^2}{2}, \frac{m^2}{4}, \theta \right), \tag{42} \]

which, in terms of the $z$ variable, result in the analog wave-functions $U(z)$

\[ U^{(1)}(z) = (1 - z^2)^{1/4} Mc \left( 1 + \frac{m^2}{2}, \frac{m^2}{4}, \arccos(z) \right) \tag{43} \]

\[ U^{(2)}(z) = (1 - z^2)^{1/4} Ms \left( 1 + \frac{m^2}{2}, \frac{m^2}{4}, \arccos(z) \right) \tag{44} \]

(see [16] for details about Mathieu functions).

As mentioned above, the boundary conditions of the present problem are \{\(U(z = \pm 1) = 0, \ U'(z = \pm 1) \) finite\}, related to finite $u(y)$ solutions to the original equation, recalling that $y \in (-\infty, \infty)$. The first set of solutions, $U^{(1)}(z)$, is not physically interesting because the derivatives of these functions are divergent at the boundary. The reason is that $Mc(\arccos(z))$ cannot be zero at $z = 1$ for any value of $m$. The second set, on the other hand, has physically acceptable solutions for a discrete set of values of $m$, the (twenty) first of which we show in Table II. These solutions are symmetric or antisymmetric, as expected (see Fig. 4). Note the presence of a zero mode.
In terms of \( y \), we have

\[
\begin{align*}
    u^{(1)}(y) &= \cosh y \, Mc \left( 1 + \frac{m^2}{2}, \frac{m^2}{4}, \arccos(\tanh y) \right) \\
    u^{(2)}(y) &= \cosh y \, Ms \left( 1 + \frac{m^2}{2}, \frac{m^2}{4}, \arccos(\tanh y) \right),
\end{align*}
\]

where the set \( u^{(1)}(y) \) diverges when \( y \to \pm \infty \), as due from the comments above, so we just keep the solutions \( u^{(2)}(y) \) (see Figs. 5 and 6).
4. The case $c = 3/8$

Now, Eq. (39) reads

$$M''(\theta) + \left(\frac{m^2}{2} - \frac{m^2}{2} \cos(2\theta)\right) M(\theta) = 0$$

(47)

with solutions given by

$$M^{(1)}(\theta) = Mc \left(\frac{m^2}{2}, \frac{m^2}{4}, \theta\right)$$

(48)

$$M^{(2)}(\theta) = Ms \left(\frac{m^2}{2}, \frac{m^2}{4}, \theta\right),$$

(49)

corresponding to

$$U^{(1)}(z) = (1 - z^2)^{1/4} Mc \left(\frac{m^2}{2}, \frac{m^2}{4}, \arccos(z)\right)$$

(50)

$$U^{(2)}(z) = (1 - z^2)^{1/4} Ms \left(\frac{m^2}{2}, \frac{m^2}{4}, \arccos(z)\right).$$

(51)

in the $z$ space with the boundary conditions already seen.

Table II. List of the first 20 values of $m_s$ and $m_a$ for $c = 3/8$.

... ...
Figure 7. Symmetric solutions $U^{(2)}(z)$ for $c = 3/8$; $m = 1.14718042$ (solid black line), $m = 4.30206964$ (long-dashed blue line), $m = 7.44879288$ (dashed red line), and $m = 13.73629872$ (solid green line).

Figure 8. Antisymmetric solutions $U^{(2)}(z)$ for $c = 3/8$; $m = 2.72632477$ (solid black line), $m = 5.87592007$ (long-dashed blue line), $m = 9.02110025$ (dashed red line), and $m = 15.30771212$ (solid green line).

As we discussed in the previous ($c = 5/8$) case, only the second set of solutions is physically relevant and just for a discrete (infinite) sequence of $m$ eigenvalues. For such values solutions have definite parity according to $\mathcal{V}(z)$, Eq. (28), (see Figs. (7) and (8)).

Note that the solutions to the Schrodinger equation (the analytical expressions (50) and (51)) are not compatible with a zero-mode for the $z$-boundary conditions given above. Actually, as a general result, for any value excluded from the sequence starting in Table II, $U^{(1)}(z)$ -eq. (50)- has divergent derivatives at $z = \pm 1$ and $U^{(2)}(z)$ -eq. (51)- is not even symmetric. For this reason the zero-mass solutions of eq. (17), $M(\theta, m = 0) \in \{\text{cons.}, \theta\}$,
do not correspond to valid solutions of the Schrodinger problem. In Fig. 9 we can see all the first mass values of the sequence which nullify the Mathieu functions $M_s$ at the boundary. These values, also listed in Table III, guarantee finite derivatives of $U^{(2)}(z)$. The absence of the zero mode in this list indicates a limitation of the Schrodinger analogue approach. We will come again to this point in the next Section. In terms of $y$ we have

\begin{align}
    u^{(1)}(y) &= M_c \left( \frac{m^2}{2}, \frac{m^2}{4}, \arccos(\tanh y) \right) \\
    u^{(2)}(y) &= M_s \left( \frac{m^2}{2}, \frac{m^2}{4}, \arccos(\tanh y) \right),
\end{align}

of which $u^{(2)}$ represents the only non-divergent set of solutions, as we illustrate in Figs. 10 and 11 for the first quantum values of $m$.

V. THE CONFLUENT HEUN EQUATION

We now investigate our original problem by relaxing the quantum analogy condition. In order to obtain the general solution of Eq. (22) we perform the following change of variable

\[ x = \tanh y. \tag{54} \]

It maps the $y$ space to $x \in (-1, 1)$ and we will eventually transform it back in order to come into the original space and variables. Note that Eq. (22) is symmetric under a parity transformation and thus the differential equation admits even as well as odd parity solutions, as it should. Now, Eq. (22) becomes
\[ u''(x) + (2 - \tilde{c}) \frac{x}{x^2 - 1} u'(x) + m^2 (1 - x^2)^{3/2} u(x) = 0. \] (55)

which is an homogeneous second-order linear differential equation with polynomial coefficients provided \( a \) is even. Here \( \tilde{c} = a(1 - 2c) \) so that \( \tilde{c} = (-\infty, a) \). Now, Eq. (55) looks more familiar if we change \( x^2 \) into \( z \)

\[ u''(z) + \left( \frac{1/2}{z} + \frac{1 - \tilde{c}/2}{z - 1} \right) u'(z) + \frac{m^2 u(z)}{4 z} = 0. \] (56)

Figure 10. Symmetric solutions \( u^{(2)}(y) \), eq.(53), for \( c = 3/8; \) \( m = 1.14718042 \) (solid black line), \( m = 4.30206964 \) (long-dashed blue line), \( m = 7.44879288 \) (dashed red line), and \( m = 13.73629872 \) (solid black line).

Figure 11. Antisymmetric solutions \( u^{(2)}(y) \), eq.(53), for \( c = 3/8; \) \( m = 2.72632477 \) (solid black line), \( m = 5.87592007 \) (long-dashed blue line), \( m = 9.02110025 \) (dashed red line), and \( m = 15.30771212 \) (solid black line).
for the case under study. Formally, this equation has two regular singular (Fuchsian) points at \( z = 0, 1 \), and an irregular one at \( z = \infty \). This is known as a Confluent Heun equation [17–19].

We can compare Eq. (56) with the canonical non-symmetrical general form of the confluent Heun equation as given in [18–20]

\[
Hc''(z) + \left( \frac{\beta + 1}{z} + \frac{\gamma + 1}{z - 1} \right) Hc'(z) + \left[ \frac{\delta + \frac{\eta}{2}(\beta + \gamma + 2)}{z(z - 1)} \right] Hc(z) = 0,
\]

(57)

whose solutions around \( z = 0 \) are denoted by

\[
H^{(1)} = Hc(\alpha, \beta, \gamma, \delta, \eta; z)
\]

(58)

\[
H^{(2)} = z^{-\beta} Hc(\alpha, -\beta, \gamma, \delta, \eta; z).
\]

(59)

In general, there are two linearly independent local series solutions around each singular point. In the region of interest, \( z < 1 \), we look for a regular local solution around \( z = 0 \) which is defined by the Heun series as

\[
Hc(z) = \sum_{n=0}^{\infty} d_n z^n.
\]

(60)

Here the constants \( d_n \) (with \( d_{-1} = 0 \) and \( d_0 = 1 \)) are determined by the three-term recurrence relation [21]

\[
A_n d_n = B_n d_{n-1} + C_n d_{n-2},
\]

(61)

where

\[
A_n = 1 + \frac{\beta}{n} \to 1 - \frac{1}{2n}
\]

(62)

\[
B_n = 1 + \frac{\eta + (\alpha - \beta - \gamma)/2 - \alpha \beta/2 + \beta \gamma/2}{n^2} \to 1 + \frac{-\tilde{c}/2 - 3/2}{n^2} + \frac{\tilde{c}/2 + 1/2 - m^2/4}{n^2}
\]

(63)

\[
C_n = \frac{1}{n^2} \left( \delta + \frac{\alpha(\beta + \gamma)}{2} + \alpha(n - 1) \right) \to \frac{m^2}{4n^2}.
\]

(64)

By comparing Eqs. (56) and (57), it is easy to identify \( \alpha = 0, \beta = -1/2, \gamma = -\tilde{c}/2, \delta = m^2/4, \) and \( \eta = \tilde{c}/8 + 1/4 - m^2/4 \). Then the solutions of Eq. (22) are given by

\[
u^{(1)}(y) = Hc \left( 0, -\frac{1}{2}, -\frac{\tilde{c}}{2}, \frac{m^2}{4}, \frac{1}{4} + \frac{\tilde{c}}{8} - \frac{m^2}{4}; \tanh^2 y \right)
\]

(65)

\[
u^{(2)}(y) = \tanh y Hc \left( 0, \frac{1}{2}, -\frac{\tilde{c}}{2}, \frac{m^2}{4}, \frac{1}{4} + \frac{\tilde{c}}{8} - \frac{m^2}{4}; \tanh^2 y \right)
\]

(66)
for arbitrary values of \( \tilde{c} \) (or \( c \)), namely of the dilaton coupling constant. The conditions these Heun \( u(y) \) solutions must obey to be acceptable are the original ones, i.e. finiteness and continuity in the whole space.

Table III. List of first values of \( m_s \) and \( m_a \) for \( \tilde{c} = -30 \).

| \( m_s \)     | \( m_a \)     |
|--------------|--------------|
| 0            | --           |
| 8.69355330   | 5.90953031   |
| 13.16860126  | 11.03547247  |
| 17.10643340  | 15.17836781  |
| 20.80307154  | 18.97642242  |
| 24.36269818  | 22.59620420  |
| \ldots       | \ldots       |

Figure 12. Symmetric solutions of the Heun equation \((\tilde{c} = -30)\) for \( m = 0 \) (black dash-doted), \( m = 8.69355330 \) (blue dashed), \( m = 13.16860126 \) (red dashed), \( m = 17.10643340 \) (black solid), \( m = 20.80307154 \) (brown solid), \( m = 24.36269818 \) (orange solid). Curves required masses with thirty significant digits of which only the first are shown. (a) Solutions eq. \((65)\) near the origin

A noteworthy point in the present approach is that now, depending on \( \tilde{c} \), the mass values \( m^2 \) can be quantized, as we saw in Sect. [IV] or not, as we will explain in what follows.

After a lengthy numerical exam, we found clear evidence that for \( \tilde{c} \leq 0 \) (namely \( \lambda \geq \lambda_1 \equiv 15/17\lambda_0 \)) all the mass spectra are discrete. For \( \tilde{c} \in (0, 4) \), \( \lambda_0 < \lambda < \lambda_1 \), on the other hand, the corresponding spectra start with a zero mode and grow continuously. This sharp
Figure 13. Antisymmetric solutions of the Heun equation ($\tilde{c} = -30$) for $m = 5.90953031$ (black solid), $m = 11.03547247$ (blue dashed), $m = 15.17836781$ (red dashed), $m = 18.97642242$ (brown solid). (a) Solutions eq.(66) near the origin.

contrast may be traced back to eq. (22) where the second term of the differential equation flips precisely with the sign of $\tilde{c}$. Note that for any well-behaved solution $u(y)$, the third term of eq. (22) can be disregarded at infinity. The remainder differential equation can be easily solved showing that, for $\tilde{c} > 0$, solutions are always convergent to zero and for $\tilde{c} \leq 0$ they diverge at the boundary. Guided by this result, we performed a numerical survey in each region arriving at the conclusion above: for $\tilde{c} > 0$ there exist physical solutions for arbitrary $m$ while, otherwise, only a discrete sequence of masses allow for finite solutions at the border.

It should be mentioned that for small values of $\tilde{c}$ the solutions stabilize quickly. On the contrary, for $\tilde{c} \lesssim -10$ the numerical calculation is more difficult and more digits are needed in the mass precision to stabilize solutions at large values of $y$. For example, for $\tilde{c} = -30$, which corresponds to $\lambda = 0$, more than thirty significant digits were necessary in the mass spectrum to find the solutions as shown in Figs. 12 and 13. In Table II we listed the first values of the mass up to the eighth decimal place.

As awaited, for the cases studied in the previous Section we find again the same results. Note however that the zero-mode in the $\tilde{c} = 1$ ($c = 3/8$) case now appears explicitly. This was expected since there exists an analytical $m = 0$ solution to Eq. (22), namely $u_0(y) = e_1 \arctan(e^y) + e_2$, which must be present in a full approach. Furthermore, for $\tilde{c} = 1$ the Heun solution indicates that Table II would not only start from zero but would also be continuously filled in as mentioned above. In Figs. 14 and 15 we can see finite analytic
Heun solutions, given by eq. (65) and eq. (66), for some arbitrary values of $m$ besides the quantum-mechanical analog ones. Another way to see it is by means Fig. 16 and Fig. 17 where $m$ has been fixed arbitrarily to one of the eigenvalues of $\tilde{c} = 1$ and $\tilde{c}$ is then varied. In the $\tilde{c} = -1$ ($c = 5/8$) case the spectrum still obeys quantized values as given in Table I.

Figure 14. Symmetric solutions Eq. (65) for $\tilde{c} = 1$; $m = 0$ (dash-dotted black line), $m = 1.14718042$ (solid black line), $m = 4$ (dot green line), $m = 4.30206964$ (solid blue line), $m = 7$ (dashed black line), and $m = 7.44879288$ (solid red line).

Figure 15. Antisymmetric solutions Eq. (66) for $\tilde{c} = 1$; $m = 0$ (solid black line), $m = 2.726324772$ (solid blue line), $m = 3.5$ (dotted green line), $m = 5$ (long-dashed black line), $m = 5.5$ (dashed black line), and $m = 5.875920066$ (solid red line).

Thus, although Mathieu functions have been sufficient to characterize a part of the spectrum of the Schrodinger analog of our problem, we actually need to consider confluent Heun functions to cover all the cases. In other words, even when we achieved fully analytical solutions of the quantum analog differential equation, the spectra appeared just discrete not
Figure 16. Symmetric Heun solutions, Eq. (65), for $m = 4.30206964$ and several values of $\tilde{c}$: $\tilde{c} = 0.7$ (solid black line), $\tilde{c} = 1$ (long-dashed blue line), $\tilde{c} = 1.5$ (solid red line), $\tilde{c} = 2$ (dashed green line), and $\tilde{c} = 3$ (dotted black line).

Figure 17. Antisymmetric Heun solutions, Eq. (66), for $m = 2.72632477$ and several values of $\tilde{c}$: $\tilde{c} = 0.7$ (solid black line), $\tilde{c} = 1$ (long-dashed blue line), $\tilde{c} = 1.5$ (solid red line), $\tilde{c} = 2$ (dashed green line), and $\tilde{c} = 3$ (dotted black line).

revealing that some of them could be eventually continua.

The set of confluent Heun functions therefore provide all the possible physical solutions of the actual problem in the 5D space. This was not apparent from the Hamiltonian point of view which assumes the Sturm-Liouville operator $\mathcal{H} = \left[-\frac{d^2}{dz^2} + \mathcal{V}(z)\right]$ to represent the physical situation.
VI. FINAL REMARKS AND CONCLUSION

In order to physically assess massive modes, one can evaluate the variation of the effective gauge coupling as a function of the Kaluza-Klein masses. Actually, KK contributions can not be significant as compared with the Coulomb potential because the coupling of massive modes to (fermion) matter on the brane develops a Yukawa type potential in the non-relativistic limit. To show that this is a decreasing function of $m$ we should evaluate the coefficients that multiply the relevant sector of the four-dimensional action

$$\sim \int dy \ e^{\Sigma(y) - \Lambda \Pi(y)/2} \left( u^2_{m=0}(y) + \sum_n u^2_{mn}(y) \right) \int d^4x f f^{\mu \nu}.$$  \hspace{1cm} (67)

However, in order to simplify this computation we can assume that the coupling with the brane takes place exactly on the 4D ordinary space-time, namely at $y = 0$. It is precisely at this value of $y$ where the relevant physical effects should be much stronger. For simplicity let us consider the series of the quantum analog eigenvalues which serves as a discrete representative of the continuum. Thus, the effective 4D electrostatic potential would read

$$V(r) \sim q_1 q_2 \left( \frac{e^0}{r} + \sum_n e^{-m_n} \frac{r}{u^2_{mn}(0)} \right)$$  \hspace{1cm} (68)

where $q_1, q_2$ are two test charges separated a distance $r$ in ordinary 3D space and the Kaluza-Klein masses $m$ are numbered with $n$ in ascending order. See Fig. 14 where the first $u^{(1)}_{even}(y)$ modes are fully displayed, and Fig. 18 where the first and the tenth modes are compared. See Fig. 19 to appreciate the first 10 values at the origin. This, together with the negative exponential factor, essentially decouples the massive modes from the physics on the domain wall. Far from the membrane, all massive modes become constants like the zero-mode is, and as a consequence the 5D phenomenology results completely modified from ordinary 4D electromagnetism. See e.g. Refs. [2, 12] for the study of this issue in the case of gravity.

In this paper we have studied bulk and four-dimensional gauge propagation modes in a warped extra-dimensional space with a dilaton field. We have set up a sine-Gordon thick membrane which bounces at the extra-coordinate origin. A five-dimensional metric was dynamically generated consistently with the soliton brane and the dilaton background. In such a framework we studied the solutions of a five-dimensional gauge field.
Figure 18. First and tenth even KK eigenmodes exhibit their relative weights.

Figure 19. Sequence of the first KK values of $u_{\text{even}}^2(0)$ for $c = 3/8$ displaying the relative weights of the KK modes on the brane.

First, we have found the exact quantum-mechanical analog of our original five-dimensional stringy problem. We have shown that the corresponding Schrödinger potential function is a quotient of simple second- and fourth-order polynomials that we could solve analytically. We next obtained the exact quantum-mechanical analog eigenspectrum and used it as a guide to analyze eventually the general solution. A localized zero-mode corresponding to the ordinary photon was guaranteed for a dilaton coupling constant above $\lambda_0$. In general, we have found that the gauge-field dynamics are analytically given by confluent Heun functions which we have displayed for several representative cases. Furthermore, in contrast to the quantum analog results, in the general approach the mass of the gauge-field modes can be arbitrary for $\lambda \in (\lambda_0, \lambda_1)$. In any case, we have shown that the Kaluza-Klein gauge spectrum is strongly attenuated on the brane as compared to the zero-mode of the theory. On the
other hand, we observed that in the bulk, far from the brane, the amplitude of an infinite tower of massive modes gets progressively relevant. Interestingly, the quantum-mechanical discrete mass eigenfunctions are completely decoupled in that region.
